

具有 Eco-mode™ 的 TPS54540 4.5V 至 42V 输入、5A 降压 直流/直流转换器

1 特性

- 轻负载条件下使用脉冲跳跃实现的高效率 Eco-mode。™
- 92mΩ 高侧金属氧化物半导体场效应晶体管 (MOSFET)
- 146μA 静态运行电流和 2μA 关断电流
- 100kHz 至 2.5MHz 的固定开关频率
- 同步至外部时钟
- 轻负载条件下使用集成型引导 (BOOT) 再充电场效应晶体管 (FET) 实现的低压降
- 可调欠压闭锁 (UVLO) 电压和滞后
- 0.8V 1% 内部电压基准
- 8 引脚 HSOP, 带有 PowerPAD™ 的封装
- -40°C 至 150°C T_J 运行范围
- 使用 TPS54540 并借助 WEBENCH® 电源设计器 创建定制设计方案增加了 WEBENCH 信息

2 应用

- 工业自动化和电机控制
- 车辆配件: 全球卫星定位系统 (GPS), 娱乐系统
- USB 专用充电端口和电池充电器
- 12V 和 24V 工业、汽车和通信电源系统

3 说明

TPS54540 是一款 42V, 5A, 降压稳压器, 此稳压器具有一个集成的高侧 MOSFET。按照 ISO 7637 标准, 此器件能够耐受高达 45V 的抛负载脉冲。电流模式控制提供了简单的外部补偿和灵活的组件选择。一个低纹波脉冲跳跃模式将无负载时的电源电流减小至 146μA。当启用引脚被拉至低电平时, 关断电源电流被减少至 2μA。

欠压闭锁在内部设定为 4.3V, 但可用使能引脚将其提高。输出电压启动斜升由内部控制以提供一个受控的启动并且消除过冲。

宽开关频率范围可实现对效率或者外部组件尺寸的优化。输出电流是受限的逐周期电流。频率折返和热关断在过载条件下保护内部和外部组件。

TPS54540 可提供 8 引脚热增强型 HSOP PowerPAD™ 封装。

4 修订历史记录

Changes from Revision A (March 2014) to Revision B	Page
• 在特性、详细设计流程和器件支持部分.....	1
• Changed the <i>Handling Ratings</i> table To <i>ESD Ratings</i> table.....	5
• Changed V_{IN} MIN Value From: 4.5 V To: $V_O + V_{DO}$, and added Note 1 in the <i>Recommended Operating Conditions</i>	5
• Deleted last graph: "5 V Start and Stop Voltage" from the <i>Typical Characteristics</i>	10
• Updated text and added Equation 1 in the <i>Low Dropout Operation and Bootstrap Voltage (BOOT)</i>	13
• Deleted text: "The start and stop voltage for a typical 5 V..." from the <i>Low Dropout Operation and Bootstrap Voltage (BOOT)</i> section.....	13
• Changed Equation 7 and Equation 8	15
• Changed Equation 27	26
• Added new section: <i>Minimum V_{IN}</i>	31
• Deleted 2 graphs named "Low Dropout Operation" from the <i>Application Curves</i> section.....	33

Changes from Original (May 2013) to Revision A	Page
• 增加了器件信息表、推荐运行条件表、引脚配置和功能部分、处理额定值表、特性说明部分、器件功能模式、应用和 实施部分、电源相关建议部分、布局部分、器件和文档支持部分以及机械、封装和可订购信息部分。.....	1
• Changed the <i>Electrical Characteristics</i> Conditions From: $V_{IN} = 4.5$ to 60 V To: $V_{IN} = 4.5$ to 42 V.....	6
• Changed the Operating: nonswitching supply current TEST CONDITIONS From: $FB = 0.83$ V To: $FB = 0.9$ V.....	6
• Changed RT/CLK high threshold MAX value From: 1.7 V To: 2 V.....	6
• Changed the title of graph "5 V Start and Stop Voltage" to include a link to the Low Dropout Operation section.	10
• Changed the FBD, removed the Logic block and Shutdown signal from the OV comparator.....	12
• Changed V_F = Forward Drop of the Catch Diode To: V_D = Forward Drop of the Catch Diode.....	14
• Deleted value $TSW = 1 / f_{sw}$ from the list following Equation 2	14
• Changed $V_{B2SW} = V_{BOOT} + V_F$ To: $V_{B2SW} = V_{BOOT} + V_D$	14
• Changed $V_{BOOT} = (1.41 \times V_{IN} - 0.554 - V_F / TSW - 1.847 \times 10^3 \times IB2SW) / (1.41 + 1 / Tsw)$ To: $V_{BOOT} = (1.41 \times V_{IN} - 0.554 - V_D \times f_{sw} - 1.847 \times 10^3 \times IB2SW) / (1.41 + f_{sw})$	14
• Deleted figure: "5V Start/Stop Voltage".....	14

- Added a title to [Figure 23](#) 14
- Changed the section title From: Selecting the Switching Frequency To: Accurate Current Limit Operation and Maximum Switching Frequency..... 16
- Changed text in the Synchronization to RT/CLK terminal section From: "0.5 V and higher than 1.7 V" To: "0.5 V and higher than 2 V" 17
- Changed [Equation 33](#) From: $(5.13V^2 - 5 V^2)$ To: $3.43 V^2 - 3.3 V^2$ 28
- Changed [Figure 36](#), VOUT From: 200 mV/div To 100 mV/div 33
- Changed [Figure 38](#) , EN From: 1 V/div To: 2 V/div, VOUT From: 4 V/div To: 2 V/div, and Time = 2 ms/div To: Time = 20 ms/div 33
- Changed [Figure 39](#) , VOUT From: 4 V/div To: 2 V/div..... 33

5 Pin Configuration and Functions

Pin Functions

TERMINAL		I/O	DESCRIPTION
NAME	NO.		
BOOT	1	O	A bootstrap capacitor is required between BOOT and SW. If the voltage on this capacitor is below the minimum required to operate the high side MOSFET, the output is switched off until the capacitor is refreshed.
VIN	2	I	Input supply voltage with 4.5 V to 42 V operating range.
EN	3	I	Enable terminal, with internal pull-up current source. Pull below 1.2 V to disable. Float to enable. Adjust the input undervoltage lockout with two resistors. See the Enable and Adjusting Undervoltage Lockout section.
RT/CLK	4	I	Resistor Timing and External Clock. An internal amplifier holds this terminal at a fixed voltage when using an external resistor to ground to set the switching frequency. If the terminal is pulled above the PLL upper threshold, a mode change occurs and the terminal becomes a synchronization input. The internal amplifier is disabled and the terminal is a high impedance clock input to the internal PLL. If clocking edges stop, the internal amplifier is re-enabled and the operating mode returns to resistor frequency programming.
FB	5	I	Inverting input of the transconductance (gm) error amplifier.
COMP	6	O	Error amplifier output and input to the output switch current (PWM) comparator. Connect frequency compensation components to this terminal.
GND	7	–	Ground
SW	8	I	The source of the internal high-side power MOSFET and switching node of the converter.
Thermal Pad	9	–	GND terminal must be electrically connected to the exposed pad on the printed circuit board for proper operation.

6 Specifications

6.1 Absolute Maximum Ratings⁽¹⁾

over operating free-air temperature range (unless otherwise noted)

		VALUE		UNIT
		MIN	MAX	
Input voltage	VIN	-0.3	45	V
	EN	-0.3	8.4	
	BOOT		53	
	FB	-0.3	3	
	COMP	-0.3	3	
	RT/CLK	-0.3	3.6	
Output voltage	BOOT-SW		8	V
	SW	-0.6	45	
	SW, 10-ns Transient	-2	45	
Operating junction temperature, T _J		-40	150	°C
Storage temperature, T _{STG}		-65	150	°C

- (1) Stresses beyond those listed under *absolute maximum ratings* may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under *recommended operating conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

		VALUE	UNIT
V _{ESD} ⁽¹⁾	Human Body Model (HBM) ESD Stress Voltage ⁽²⁾	±2000	V
	Charged Device Model (HBM) ESD Stress Voltage ⁽³⁾	±500	V

- (1) Electrostatic discharge (ESD) to measure device sensitivity and immunity to damage caused by assembly line electrostatic discharges into the device.
- (2) Level listed above is the passing level per ANSI/ESDA/JEDEC JS-001. JEDEC document JEP155 states that 500V HBM allows safe manufacturing with a standard ESD control process. terminals listed as 1000V may actually have higher performance.
- (3) Level listed above is the passing level per EIA-JEDEC JESD22-C101. JEDEC document JEP157 states that 250V CDM allows safe manufacturing with a standard ESD control process. terminals listed as 250V may actually have higher performance.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	MAX	UNIT
V _{IN}	Supply input voltage ⁽¹⁾	V _O + V _{DO}	42	V
V _O	Output voltage	0.8	41.1	V
I _O	Output current	0	5	A
T _J	Junction Temperature	-40	150	°C

- (1) See [Equation 1](#)

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾⁽²⁾		TPS54540	UNIT
		DDA (8 PINS)	
θ _{JA}	Junction-to-ambient thermal resistance (standard board)	42.0	°C/W
ψ _{JT}	Junction-to-top characterization parameter	5.9	°C/W
ψ _{JB}	Junction-to-board characterization parameter	23.4	°C/W
θ _{Jctop}	Junction-to-case(top) thermal resistance	45.8	°C/W
θ _{Jcbot}	Junction-to-case(bottom) thermal resistance	3.6	°C/W
θ _{JB}	Junction-to-board thermal resistance	23.4	v

- (1) For more information about traditional and new thermal metrics, see the IC Package Thermal Metrics application report, [SPRA953](#).
- (2) Power rating at a specific ambient temperature T_A should be determined with a junction temperature of 150°C. This is the point where distortion starts to substantially increase. See power dissipation estimate in application section of this data sheet for more information.

6.5 Electrical Characteristics

 $T_J = -40^{\circ}\text{C}$ to 150°C , $V_{IN} = 4.5$ to 42 V (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT
SUPPLY VOLTAGE (VIN TERMINAL)

7 Detailed Description

7.1 Overview

The TPS54540 is a 42 V, 5 A, step-down (buck) regulator with an integrated high side n-channel MOSFET. The device implements constant frequency, current mode control which reduces output capacitance and simplifies external frequency compensation. The wide switching frequency range of 100 kHz to 2500 kHz allows either efficiency or size optimization when selecting the output filter components. The switching frequency is adjusted using a resistor to ground connected to the RT/CLK terminal. The device has an internal phase-locked loop (PLL) connected to the RT/CLK terminal that will synchronize the power switch turn on to a falling edge of an external clock signal.

The TPS54540 has a default input start-up voltage of approximately 4.3 V. The EN terminal can be used to adjust the input undervoltage lockout (UVLO) threshold with two external resistors. An internal pull up current source enables operation when the EN terminal is floating. The operating current is 146 μ A under no load condition (not switching). When the device is disabled, the supply current is 2 μ A.

The integrated 92 m Ω high side MOSFET supports high efficiency power supply designs capable of delivering 5 amperes of continuous current to a load. The gate drive bias voltage for the integrated high side MOSFET is supplied by a bootstrap capacitor connected from the BOOT to SW terminals. The TPS54540 reduces the external component count by integrating the bootstrap recharge diode. The BOOT terminal capacitor voltage is monitored by a UVLO circuit which turns off the high side MOSFET when the BOOT to SW voltage falls below a preset threshold. An automatic BOOT capacitor recharge circuit allows the TPS54540 to operate at high duty cycles approaching 100%. Therefore, the maximum output voltage is near the minimum input supply voltage of the application. The minimum output voltage is the internal 0.8 V feedback reference.

Output overvoltage transients are minimized by an Overvoltage Transient Protection (OVP) comparator. When the OVP comparator is activated, the high side MOSFET is turned off and remains off until the output voltage is less than 106% of the desired output voltage.

The TPS54540 includes an internal soft-start circuit that slows the output rise time during start-up to reduce in-rush current and output voltage overshoot. Output overload conditions reset the soft-start timer. When the overload condition is removed, the soft-start circuit controls the recovery from the fault output level to the nominal regulation voltage. A frequency foldback circuit reduces the switching frequency during start-up and overcurrent fault conditions to help maintain control of the inductor current.

7.2 Functional Block Diagram

Copyright © 2016, Texas Instruments Incorporated

7.3 Feature Description

7.3.1 Fixed Frequency PWM Control

The TPS54540 uses fixed frequency, peak current mode control with adjustable switching frequency. The output voltage is compared through external resistors connected to the FB terminal to an internal voltage reference by an error amplifier. An internal oscillator initiates the turn on of the high side power switch. The error amplifier output at the COMP terminal controls the high side power switch current. When the high side MOSFET switch current reaches the threshold level set by the COMP voltage, the power switch is turned off. The COMP terminal voltage will increase and decrease as the output current increases and decreases. The device implements current limiting by clamping the COMP terminal voltage to a maximum level. The pulse skipping Eco-mode is implemented with a minimum voltage clamp on the COMP terminal.

7.3.2 Slope Compensation Output Current

The TPS54540 adds a compensating ramp to the MOSFET switch current sense signal. This slope compensation prevents sub-harmonic oscillations at duty cycles greater than 50%. The peak current limit of the high side switch is not affected by the slope compensation and remains constant over the full duty cycle range.

Feature Description (continued)

7.3.3 Pulse Skip Eco-mode

The TPS54540 operates in a pulse skipping Eco-mode at light load currents to improve efficiency by reducing switching and gate drive losses. If the output voltage is within regulation and the peak switch current at the end of any switching cycle is below the pulse skipping current threshold, the device enters Eco-mode. The pulse skipping current threshold is the peak switch current level corresponding to a nominal COMP voltage of 600 mV.

When in Eco-mode, the COMP terminal voltage is clamped at 600 mV and the high side MOSFET is inhibited. Since the device is not switching, the output voltage begins to decay. The voltage control loop responds to the falling output voltage by increasing the COMP terminal voltage. The high side MOSFET is enabled and switching resumes when the error amplifier lifts COMP above the pulse skipping threshold. The output voltage recovers to the regulated value, and COMP eventually falls below the Eco-mode pulse skipping threshold at which time the device again enters Eco-mode. The internal PLL remains operational when in Eco-mode. When operating at light load currents in Eco-mode, the switching transitions occur synchronously with the external clock signal.

During Eco-mode operation, the TPS54540 senses and controls peak switch current, not the average load current. Therefore the load current at which the device enters Eco-mode is dependent on the output inductor value. The circuit in [Figure 35](#) enters Eco-mode at about 18 mA output current. As the load current approaches zero, the device enters a pulse skip mode during which it draws only 146 μ A input quiescent current.

7.3.4 Low Dropout Operation and Bootstrap Voltage (BOOT)

The TPS54540 provides an integrated bootstrap voltage regulator. A small capacitor between the BOOT and SW terminals provides the gate drive voltage for the high side MOSFET. The BOOT capacitor is refreshed when the high side MOSFET is off and the external low side diode conducts. The recommended value of the BOOT capacitor is 0.1 μ F. A ceramic capacitor with an X7R or X5R grade dielectric with a voltage rating of 10 V or higher is recommended for stable performance over temperature and voltage.

When operating with a low voltage difference from input to output, the high side MOSFET of the TPS54540 will operate at 100% duty cycle as long as the BOOT to SW terminal voltage is greater than 2.1V. When the voltage from BOOT to SW drops below 2.1V, the high side MOSFET is turned off and an integrated low side MOSFET pulls SW low to recharge the BOOT capacitor. To reduce the losses of the small low side MOSFET at high output voltages, it is disabled at 24 V output and re-enabled when the output reaches 21.5 V.

Since the gate drive current sourced from the BOOT capacitor is small, the high side MOSFET can remain on for many switching cycles before the MOSFET is turned off to refresh the capacitor. Thus the effective duty cycle of the switching regulator can be high, approaching 100%. The effective duty cycle of the converter during dropout is mainly influenced by the voltage drops across the power MOSFET, the inductor resistance, the low side diode voltage and the printed circuit board resistance.

[Equation 1](#) calculates the minimum input voltage required to regulate the output voltage and ensure normal operation of the device. This calculation must include tolerance of the component specifications and the variation of these specifications at their maximum operating temperature in the application

$$V_{IN}(\min) = \frac{V_{OUT} + V_F + R_{dc} \times I_{OUT}}{0.99} + R_{DS(on)} \times I_{OUT} - V_F$$

where

- V_F = Schottky diode forward voltage
- R_{dc} = DC resistance of inductor and PCB
- $R_{DS(on)}$ = High-side MOSFET $R_{DS(on)}$

(1)

During high duty cycle (low dropout) conditions, inductor current ripple increases when the BOOT capacitor is being recharged resulting in an increase in output voltage ripple. Increased ripple occurs when the off time required to recharge the BOOT capacitor is longer than the high side off time associated with cycle by cycle PWM control.

At heavy loads, the minimum input voltage must be increased to insure a monotonic startup. [Equation 2](#) can be used to calculate the minimum input voltage for this condition.

Feature Description (continued)

$$V_{OUT(max)} = D_{(max)} \times (V_{IN(min)} - I_{OUT(max)} \times R_{DS(on)} + V_D) - V_D + I_{OUT(max)} \times R_{dc}$$

where

- $D_{(max)} \geq 0.9$
- $IB2SW = 100 \mu A$
- $V_D =$ Forward Drop of the Catch Diode
- $VB2SW = VBOOT + V_D$
- $VBOOT = (1.41 \times V_{IN} - 0.554 - V_D \times f_{SW} - 1.847 \times 10^3 \times IB2SW) / (1.41 + f_{SW})$
- $R_{DS(on)} = 1 / (-0.3 \times VB2SW^2 + 3.577 \times VB2SW - 4.246)$ (2)

7.3.5 Error Amplifier

The TPS54540 voltage regulation loop is controlled by a transconductance error amplifier. The error amplifier compares the FB terminal voltage to the lower of the internal soft-start voltage or the internal 0.8 V voltage reference. The transconductance (gm) of the error amplifier is 350 $\mu A/V$ during normal operation. During soft-start operation, the transconductance is reduced to 78 $\mu A/V$ and the error amplifier is referenced to the internal soft-start voltage.

The frequency compensation components (capacitor, series resistor and capacitor) are connected between the error amplifier output COMP terminal and GND terminal.

7.3.6 Adjusting the Output Voltage

The internal voltage reference produces a precise 0.8 V $\pm 1\%$ voltage reference over the operating temperature and voltage range by scaling the output of a bandgap reference circuit. The output voltage is set by a resistor divider from the output node to the FB terminal. It is recommended to use 1% tolerance or better divider resistors. Select the low side resistor R_{LS} for the desired divider current and use Equation 3 to calculate R_{HS} . To improve efficiency at light loads consider using larger value resistors. However, if the values are too high, the regulator will be more susceptible to noise and voltage errors from the FB input current may become noticeable.

$$R_{HS} = R_{LS} \times \left(\frac{V_{out} - 0.8V}{0.8V} \right) \quad (3)$$

7.3.7 Enable and Adjusting Undervoltage Lockout

The TPS54540 is enabled when the VIN terminal voltage rises above 4.3 V and the EN terminal voltage exceeds the enable threshold of 1.2 V. The TPS54540 is disabled when the VIN terminal voltage falls below 4 V or when the EN terminal voltage is below 1.2 V. The EN terminal has an internal pull-up current source, I1, of 1.2 μA that enables operation of the TPS54540 when the EN terminal floats.

If an application requires a higher undervoltage lockout (UVLO) threshold, use the circuit shown in Figure 22 to adjust the input voltage UVLO with two external resistors. When the EN terminal voltage exceeds 1.2 V, an additional 3.4 μA of hysteresis current, I_{HYS} , is sourced out of the EN terminal. When the EN terminal is pulled below 1.2 V, the 3.4 μA I_{hys} current is removed. This additional current facilitates adjustable input voltage UVLO hysteresis. Use Equation 4 to calculate R_{UVLO1} for the desired UVLO hysteresis voltage. Use Equation 5 to calculate R_{UVLO2} for the desired VIN start voltage.

In applications designed to start at relatively low input voltages (that is, from 4.5 V to 9 V) and withstand high input voltages (that is, up to 42 V), the EN terminal may experience a voltage greater than the absolute maximum voltage of 8.4 V during the high input voltage condition. To avoid exceeding this voltage when using the EN resistors, the EN terminal is clamped internally with a 5.8 V zener diode that will sink up to 150 μA .

Feature Description (continued)

Copyright © 2017, Texas Instruments Incorporated

Figure 22. Adjustable Undervoltage Lockout (UVLO)

$$R_{UVLO1} = \frac{V_{START} - V_{STOP}}{I_{HYS}} \tag{4}$$

$$R_{UVLO2} = \frac{V_{ENA}}{\frac{V_{START} - V_{ENA}}{R_{UVLO1}} + I_1} \tag{5}$$

7.3.8 Internal Soft-Start

The TPS54540 has an internal digital soft-start that ramps the reference voltage from zero volts to its final value in 1024 switching cycles. The internal soft-start time (10% to 90%) is calculated using Equation 6.

$$t_{SS}(ms) = \frac{1024}{f_{SW}(kHz)} \tag{6}$$

If the EN terminal is pulled below the stop threshold of 1.2 V, switching stops and the internal soft-start resets. The soft-start also resets in thermal shutdown.

7.3.9 Constant Switching Frequency and Timing Resistor (RT/CLK) Terminal)

The switching frequency of the TPS54540 is adjustable over a wide range from 100 kHz to 2500 kHz by placing a resistor between the RT/CLK terminal and GND terminal. The RT/CLK terminal voltage is typically 0.5 V and must have a resistor to ground to set the switching frequency. To determine the timing resistance for a given switching frequency, use Equation 7 or Equation 8 or the curves in Figure 5 and Figure 6. To reduce the solution size one would typically set the switching frequency as high as possible, but tradeoffs of the conversion efficiency, maximum input voltage and minimum controllable on time should be considered. The minimum controllable on time is typically 135 ns which limits the maximum operating frequency in applications with high input to output step down ratios. The maximum switching frequency is also limited by the frequency foldback circuit. A more detailed discussion of the maximum switching frequency is provided in the next section.

$$R_T (k\Omega) = \frac{101756}{f_{sw} (kHz)^{1.008}} \tag{7}$$

$$f_{sw} (kHz) = \frac{92417}{RT (k\Omega)^{0.991}} \tag{8}$$

Figure 23. Internal EN Terminal Clamp

Feature Description (continued)

7.3.10 Accurate Current Limit Operation and Maximum Switching Frequency

The TPS54540 implements peak current mode control in which the COMP terminal voltage controls the peak current of the high side MOSFET. A signal proportional to the high side switch current and the COMP terminal voltage are compared each cycle. When the peak switch current intersects the COMP control voltage, the high side switch is turned off. During overcurrent conditions that pull the output voltage low, the error amplifier increases switch current by driving the COMP terminal high. The error amplifier output is clamped internally at a level which sets the peak switch current limit. The TPS54540 provides an accurate current limit threshold with a typical current limit delay of 60 ns. With smaller inductor values, the delay will result in a higher peak inductor current. The relationship between the inductor value and the peak inductor current is shown in [Figure 24](#).

Figure 24. Current Limit Delay

To protect the converter in overload conditions at higher switching frequencies and input voltages, the TPS54540 implements a frequency foldback. The oscillator frequency is divided by 1, 2, 4, and 8 as the FB terminal voltage falls from 0.8 V to 0 V. The TPS54540 uses a digital frequency foldback to enable synchronization to an external clock during normal start-up and fault conditions. During short-circuit events, the inductor current can exceed the peak current limit because of the high input voltage and the minimum controllable on time. When the output voltage is forced low by the shorted load, the inductor current decreases slowly during the switch off time. The frequency foldback effectively increases the off time by increasing the period of the switching cycle providing more time for the inductor current to ramp down.

With a maximum frequency foldback ratio of 8, there is a maximum frequency at which the inductor current can be controlled by frequency foldback protection. [Equation 10](#) calculates the maximum switching frequency at which the inductor current will remain under control when V_{OUT} is forced to $V_{OUT(SC)}$. The selected operating frequency should not exceed the calculated value.

[Equation 9](#) calculates the maximum switching frequency limitation set by the minimum controllable on time and the input to output step down ratio. Setting the switching frequency above this value will cause the regulator to skip switching pulses to achieve the low duty cycle required at maximum input voltage.

$$f_{SW(max skip)} = \frac{1}{t_{ON}} \times \left(\frac{I_O \times R_{dc} + V_{OUT} + V_d}{V_{IN} - I_O \times R_{DS(on)} + V_d} \right) \quad (9)$$

Feature Description (continued)

$$f_{SW(shift)} = \frac{f_{DIV}}{t_{ON}} \times \left(\frac{I_{CL} \times R_{dc} + V_{OUT(sc)} + V_d}{V_{IN} - I_{CL} \times R_{DS(on)} + V_d} \right) \quad (10)$$

I_o	Output current
I_{CL}	Current limit
R_{dc}	inductor resistance
V_{IN}	maximum input voltage
V_{OUT}	output voltage
V_{OUTSC}	output voltage during short
V_d	diode voltage drop
$R_{DS(on)}$	switch on resistance
t_{ON}	controllable on time
f_{DIV}	frequency divide equals (1, 2, 4, or 8)

7.3.11 Synchronization to RT/CLK Terminal

The RT/CLK terminal can receive a frequency synchronization signal from an external system clock. To implement this synchronization feature connect a square wave to the RT/CLK terminal through either circuit network shown in Figure 25. The square wave applied to the RT/CLK terminal must switch lower than 0.5 V and higher than 2 V and have a pulsewidth greater than 15 ns. The synchronization frequency range is 160 kHz to 2300 kHz. The rising edge of the SW will be synchronized to the falling edge of RT/CLK terminal signal. The external synchronization circuit should be designed such that the default frequency set resistor is connected from the RT/CLK terminal to ground when the synchronization signal is off. When using a low impedance signal source, the frequency set resistor is connected in parallel with an ac coupling capacitor to a termination resistor (that is, 50 Ω) as shown in Figure 25. The two resistors in series provide the default frequency setting resistance when the signal source is turned off. The sum of the resistance should set the switching frequency close to the external CLK frequency. It is recommended to ac couple the synchronization signal through a 10 pF ceramic capacitor to RT/CLK terminal.

The first time the RT/CLK is pulled above the PLL threshold the TPS54540 switches from the RT resistor free-running frequency mode to the PLL synchronized mode. The internal 0.5 V voltage source is removed and the RT/CLK terminal becomes high impedance as the PLL starts to lock onto the external signal. The switching frequency can be higher or lower than the frequency set with the RT/CLK resistor. The device transitions from the resistor mode to the PLL mode and locks onto the external clock frequency within 78 microseconds. During the transition from the PLL mode to the resistor programmed mode, the switching frequency will fall to 150 kHz and then increase or decrease to the resistor programmed frequency when the 0.5 V bias voltage is reapplied to the RT/CLK resistor.

The switching frequency is divided by 8, 4, 2, and 1 as the FB terminal voltage ramps from 0 to 0.8 volts. The device implements a digital frequency foldback to enable synchronizing to an external clock during normal start-up and fault conditions. Figure 26, Figure 27 and Figure 28 show the device synchronized to an external system clock in continuous conduction mode (CCM), discontinuous conduction (DCM), and pulse skip mode (Eco-Mode).

Figure 28. Plot of Synchronizing in Eco-mode
7.3.12 Overvoltage Protection

The TPS54540 incorporates an output overvoltage protection (OVP) circuit to minimize voltage overshoot when recovering from output fault conditions or strong unload transients in designs with low output capacitance. For example, when the power supply output is overloaded the error amplifier compares the actual output voltage to the internal reference voltage. If the FB terminal voltage is lower than the internal reference voltage for a considerable time, the output of the error amplifier will increase to a maximum voltage corresponding to the peak current limit threshold. When the overload condition is removed, the regulator output rises and the error amplifier output transitions to the normal operating level. In some applications, the power supply output voltage can increase faster than the response of the error amplifier output resulting in an output overshoot.

Feature Description (continued)

The OVP feature minimizes output overshoot when using a low value output capacitor by comparing the FB terminal voltage to the rising OVP threshold which is nominally 109% of the internal voltage reference. If the FB terminal voltage is greater than the rising OVP threshold, the high side MOSFET is immediately disabled to minimize output overshoot. When the FB voltage drops below the falling OVP threshold which is nominally 106% of the internal voltage reference, the high side MOSFET resumes normal operation.

7.3.13 Thermal Shutdown

The TPS54540 provides an internal thermal shutdown to protect the device when the junction temperature exceeds 176°C. The high side MOSFET stops switching when the junction temperature exceeds the thermal trip threshold. Once the die temperature falls below 164°C, the device reinitiates the power up sequence controlled by the internal soft-start circuitry.

7.3.14 Small Signal Model for Loop Response

Figure 29 shows an equivalent model for the TPS54540 control loop which can be simulated to check the frequency response and dynamic load response. The error amplifier is a transconductance amplifier with a $g_{m_{EA}}$ of 350 $\mu\text{A/V}$. The error amplifier can be modeled using an ideal voltage controlled current source. The resistor R_O and capacitor C_O model the open loop gain and frequency response of the amplifier. The 1mV ac voltage source between the nodes a and b effectively breaks the control loop for the frequency response measurements. Plotting c/a provides the small signal response of the frequency compensation. Plotting a/b provides the small signal response of the overall loop. The dynamic loop response can be evaluated by replacing R_L with a current source with the appropriate load step amplitude and step rate in a time domain analysis. This equivalent model is only valid for continuous conduction mode (CCM) operation.

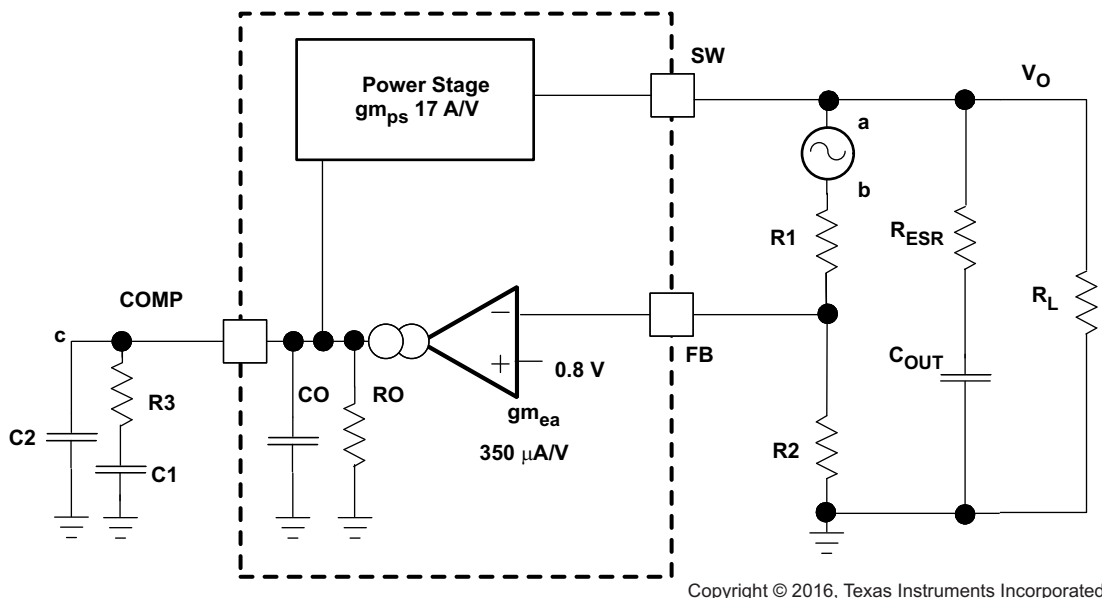

Figure 29. Small Signal Model for Loop Response

7.3.15 Simple Small Signal Model for Peak Current Mode Control

Figure 30 describes a simple small signal model that can be used to design the frequency compensation. The TPS54540 power stage can be approximated by a voltage-controlled current source (duty cycle modulator) supplying current to the output capacitor and load resistor. The control to output transfer function is shown in Equation 11 and consists of a dc gain, one dominant pole, and one ESR zero. The quotient of the change in switch current and the change in COMP terminal voltage (node c in Figure 29) is the power stage transconductance, $g_{m_{PS}}$. The $g_{m_{PS}}$ for the TPS54540 is 17 A/V. The low-frequency gain of the power stage is the product of the transconductance and the load resistance as shown in Equation 12.

Feature Description (continued)

As the load current increases and decreases, the low-frequency gain decreases and increases, respectively. This variation with the load may seem problematic at first glance, but fortunately the dominant pole moves with the load current (see [Equation 13](#)). The combined effect is highlighted by the dashed line in the right half of [Figure 30](#). As the load current decreases, the gain increases and the pole frequency lowers, keeping the 0-dB crossover frequency the same with varying load conditions. The type of output capacitor chosen determines whether the ESR zero has a profound effect on the frequency compensation design. Using high ESR aluminum electrolytic capacitors may reduce the number frequency compensation components needed to stabilize the overall loop because the phase margin is increased by the ESR zero of the output capacitor (see [Equation 14](#)).

Figure 30. Simple Small Signal Model and Frequency Response for Peak Current Mode Control

Feature Description (continued)

$$\frac{V_{OUT}}{V_C} = A_{dc} \times \frac{\left(1 + \frac{s}{2\pi \times f_Z}\right)}{\left(1 + \frac{s}{2\pi \times f_P}\right)} \tag{11}$$

$$A_{dc} = g_{m_{ps}} \times R_L \tag{12}$$

$$f_P = \frac{1}{C_{OUT} \times R_L \times 2\pi} \tag{13}$$

$$f_Z = \frac{1}{C_{OUT} \times R_{ESR} \times 2\pi} \tag{14}$$

7.3.16 Small Signal Model for Frequency Compensation

The TPS54540 uses a transconductance amplifier for the error amplifier and supports three of the commonly-used frequency compensation circuits. Compensation circuits Type 2A, Type 2B, and Type 1 are shown in Figure 31. Type 2 circuits are typically implemented in high bandwidth power-supply designs using low ESR output capacitors. The Type 1 circuit is used with power-supply designs with high-ESR aluminum electrolytic or tantalum capacitors. Equation 15 and Equation 16 relate the frequency response of the amplifier to the small signal model in Figure 31. The open-loop gain and bandwidth are modeled using the R_O and C_O shown in Figure 31. See the application section for a design example using a Type 2A network with a low ESR output capacitor.

Equation 15 through Equation 24 are provided as a reference. An alternative is to use WEBENCH software tools to create a design based on the power supply requirements.

7.4 Device Functional Modes

7.4.1 Operation with $V_{IN} < 4.5\text{ V}$ (Minimum V_{IN})

The device is recommended to operate with input voltages above 4.5 V. The typical V_{IN} UVLO threshold is 4.3 V and the device may operate at input voltages down to the UVLO voltage. At input voltages below the actual UVLO voltage, the device will not switch. If EN is externally pulled up to V_{IN} or left floating, when V_{IN} passes the UVLO threshold the device will become active. Switching is enabled, and the soft start sequence is initiated. The TPS54540 will start at the soft start time determined by the internal soft start time.

7.4.2 Operation with EN Control

The enable threshold voltage is 1.2 V typical. With EN held below that voltage the device is disabled and switching is inhibited even if V_{IN} is above its UVLO threshold. The IC quiescent current is reduced in this state. If the EN voltage is increased above the threshold while V_{IN} is above its UVLO threshold, the device becomes active. Switching is enabled, and the soft start sequence is initiated. The TPS54540 will start at the soft start time determined by the internal soft start time.

7.4.3 Alternate Power Supply Topologies

7.4.3.1 Inverting Power

The TPS54540 can be used to convert a positive input voltage to a negative output voltage. Idea applications are amplifiers requiring a negative power supply. For a more detailed example see [SLVA317](#).

8 Application and Implementation

NOTE

Information in the following applications and Implementation sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

8.1 Application Information

The TPS54540 is a 42 V, 5 A, step down regulator with an integrated high side MOSFET. Idea applications are: 12 V and 24 V Industrial, Automotive and Communications Power Systems.

8.2 Typical Application

Figure 35. 3.3 V Output TPS54540 Design Example

8.2.1 Design Requirements

This guide illustrates the design of a high frequency switching regulator using ceramic output capacitors. A few parameters must be known in order to start the design process. These requirements are typically determined at the system level. Calculations can be done with the aid of WEBENCH or the excel spreadsheet (SLVC452) located on the product page. For this example, start with the following known parameters:

Table 1. Design Parameters

PARAMETER	VALUE
Output Voltage	3.3 V
Transient Response 1.25 A to 3.75 A load step	$\Delta V_{OUT} = 4\%$
Maximum Output Current	5 A
Input Voltage	12 V nom. 6 V to 42 V
Output Voltage Ripple	0.5% of V_{OUT}
Start Input Voltage (rising VIN)	5.75 V
Stop Input Voltage (falling VIN)	4.5 V

8.2.2 Detailed Design Procedure

8.2.2.1 Custom Design with WEBENCH® Tools

[Click here](#) to create a custom design using the TPS54540 device with the WEBENCH® Power Designer.

1. Start by entering your V_{IN} , V_{OUT} , and I_{OUT} requirements.
2. Optimize your design for key parameters like efficiency, footprint and cost using the optimizer dial and compare this design with other possible solutions from Texas Instruments.
3. The WEBENCH Power Designer provides you with a customized schematic along with a list of materials with real time pricing and component availability.
4. In most cases, you will also be able to:
 - Run electrical simulations to see important waveforms and circuit performance
 - Run thermal simulations to understand the thermal performance of your board
 - Export your customized schematic and layout into popular CAD formats
 - Print PDF reports for the design, and share your design with colleagues
5. Get more information about WEBENCH tools at www.ti.com/WEBENCH.

8.2.2.2 Selecting the Switching Frequency

The first step is to choose a switching frequency for the regulator. Typically, the designer uses the highest switching frequency possible since this produces the smallest solution size. High switching frequency allows for lower value inductors and smaller output capacitors compared to a power supply that switches at a lower frequency. The switching frequency that can be selected is limited by the minimum on-time of the internal power switch, the input voltage, the output voltage and the frequency foldback protection.

[Equation 9](#) and [Equation 10](#) should be used to calculate the upper limit of the switching frequency for the regulator. Choose the lower value result from the two equations. Switching frequencies higher than these values results in pulse skipping or the lack of overcurrent protection during a short circuit.

The typical minimum on time, t_{onmin} , is 135 ns for the TPS54540. For this example, the output voltage is 3.3 V and the maximum input voltage is 42 V. Assuming a diode voltage of 0.52 V, inductor DC resistance of 10.3 m Ω , typical switch resistance of 92 m Ω and 5 A load, from [Equation 25](#) the maximum switch frequency to avoid pulse skipping is 680 kHz. To ensure overcurrent runaway is not a concern during short circuits use [Equation 26](#) to determine the maximum switching frequency for frequency foldback protection. With a current limit value of 6.3 A and short circuit output voltage of 0.1 V, the maximum switching frequency is 960 kHz.

For this design, a lower switching frequency of 400 kHz is chosen to operate comfortably below the calculated maximums. To determine the timing resistance for a given switching frequency, use [Equation 27](#) or the curve in [Figure 6](#). The switching frequency is set by resistor R_3 shown in [Figure 35](#). For 400 kHz operation, the closest standard value resistor is 243 k Ω .

$$f_{SW(max\ skip)} = \frac{1}{135ns} \times \left(\frac{5\ A \times 10.3\ m\Omega + 3.3\ V + 0.52\ V}{42\ V - 5\ A \times 92\ m\Omega + 0.52\ V} \right) = 680\ kHz \quad (25)$$

$$f_{SW(shift)} = \frac{8}{135\ ns} \times \left(\frac{6.3\ A \times 10.3\ m\Omega + 0.1\ V + 0.52\ V}{42\ V - 6.3\ A \times 92\ m\Omega + 0.52\ V} \right) = 960\ kHz \quad (26)$$

$$RT\ (k\Omega) = \frac{101756}{400\ (kHz)^{1.008}} = 242\ k\Omega \quad (27)$$

8.2.2.3 Output Inductor Selection (L_O)

To calculate the minimum value of the output inductor, use [Equation 28](#).

K_{IND} is a ratio that represents the amount of inductor ripple current relative to the maximum output current. The inductor ripple current is filtered by the output capacitor. Therefore, choosing high inductor ripple currents impacts the selection of the output capacitor since the output capacitor must have a ripple current rating equal to or greater than the inductor ripple current. In general, the inductor ripple value is at the discretion of the designer, however, the following guidelines may be used.

For designs using low ESR output capacitors such as ceramics, a value as high as $K_{IND} = 0.3$ may be desirable. When using higher ESR output capacitors, $K_{IND} = 0.2$ yields better results. Since the inductor ripple current is part of the current mode PWM control system, the inductor ripple current should always be greater than 150 mA for stable PWM operation. In a wide input voltage regulator, it is best to choose relatively large inductor ripple current. This provides sufficient ripple current with the input voltage at the minimum.

For this design example, $K_{IND} = 0.3$ and the inductor value is calculated to be 5.1 μH . It is important that the RMS current and saturation current ratings of the inductor not be exceeded. The RMS and peak inductor current can be found from [Equation 30](#) and [Equation 31](#). For this design, the RMS inductor current is 5 A and the peak inductor current is 5.79 A. The chosen inductor is a WE 744325550, which has a saturation current rating of 12 A and an RMS current rating of 10 A. This also has a typical inductance of 5.5 μH at no load and 4.8 μH at 5 A load. Lastly it has a DCR of 10.3 m Ω .

As the equation set demonstrates, lower ripple currents will reduce the output voltage ripple of the regulator but will require a larger value of inductance. Selecting higher ripple currents will increase the output voltage ripple of the regulator but allow for a lower inductance value.

The current flowing through the inductor is the inductor ripple current plus the output current. During power up, faults or transient load conditions, the inductor current can increase above the peak inductor current level calculated above. In transient conditions, the inductor current can increase up to the switch current limit of the device. For this reason, the most conservative design approach is to choose an inductor with a saturation current rating equal to or greater than the switch current limit of the TPS54540 which is nominally 7.5 A.

$$L_{O(\min)} = \frac{V_{IN(\max)} - V_{OUT}}{I_{OUT} \times K_{IND}} \times \frac{V_{OUT}}{V_{IN(\max)} \times f_{SW}} = \frac{42 \text{ V} - 3.3 \text{ V}}{5 \text{ A} \times 0.3} \times \frac{3.3 \text{ V}}{42 \text{ V} \times 400 \text{ kHz}} = 5.1 \mu\text{H} \quad (28)$$

$$I_{RIPPLE} = \frac{V_{OUT} \times (V_{IN(\max)} - V_{OUT})}{V_{IN(\max)} \times L_O \times f_{SW}} = \frac{3.3 \text{ V} \times (42 \text{ V} - 3.3 \text{ V})}{42 \text{ V} \times 4.8 \mu\text{H} \times 400 \text{ kHz}} = 1.58 \text{ A} \quad (29)$$

$$I_{L(\text{rms})} = \sqrt{(I_{OUT})^2 + \frac{1}{12} \times \left(\frac{V_{OUT} \times (V_{IN(\max)} - V_{OUT})}{V_{IN(\max)} \times L_O \times f_{SW}} \right)^2} = \sqrt{(5 \text{ A})^2 + \frac{1}{12} \times \left(\frac{3.3 \text{ V} \times (42 \text{ V} - 3.3 \text{ V})}{42 \text{ V} \times 4.8 \mu\text{H} \times 400 \text{ kHz}} \right)^2} = 5 \text{ A} \quad (30)$$

$$I_{L(\text{peak})} = I_{OUT} + \frac{I_{RIPPLE}}{2} = 5 \text{ A} + \frac{1.58 \text{ A}}{2} = 5.79 \text{ A} \quad (31)$$

8.2.2.4 Output Capacitor

There are three primary considerations for selecting the value of the output capacitor. The output capacitor determines the modulator pole, the output voltage ripple, and how the regulator responds to a large change in load current. The output capacitance needs to be selected based on the most stringent of these three criteria.

The desired response to a large change in the load current is the first criteria. The output capacitor needs to supply the increased load current until the regulator responds to the load step. A regulator does not respond immediately to a large, fast increase in the load current such as transitioning from no load to a full load. The regulator usually needs two or more clock cycles for the control loop to sense the change in output voltage and adjust the peak switch current in response to the higher load. The output capacitance must be large enough to supply the difference in current for 2 clock cycles to maintain the output voltage within the specified range. Equation 32 shows the minimum output capacitance necessary, where ΔI_{OUT} is the change in output current, f_{sw} is the regulators switching frequency and ΔV_{OUT} is the allowable change in the output voltage. For this example, the transient load response is specified as a 4% change in V_{OUT} for a load step from 1.25 A to 3.75 A. Therefore, ΔI_{OUT} is 3.75 A - 1.25 A = 2.5 A and $\Delta V_{OUT} = 0.04 \times 3.3 \text{ V} = 0.13 \text{ V}$. Using these numbers gives a minimum capacitance of 95 μF . This value does not take the ESR of the output capacitor into account in the output voltage change. For ceramic capacitors, the ESR is usually small enough to be ignored. Aluminum electrolytic and tantalum capacitors have higher ESR that must be included in load step calculations.

The output capacitor must also be sized to absorb energy stored in the inductor when transitioning from a high to low load current. The catch diode of the regulator can not sink current so energy stored in the inductor can produce an output voltage overshoot when the load current rapidly decreases. A typical load step response is shown in Figure 36. The excess energy absorbed in the output capacitor will increase the voltage on the capacitor. The capacitor must be sized to maintain the desired output voltage during these transient periods. Equation 33 calculates the minimum capacitance required to keep the output voltage overshoot to a desired value, where L_O is the value of the inductor, I_{OH} is the output current under heavy load, I_{OL} is the output under light load, V_f is the peak output voltage, and V_i is the initial voltage. For this example, the worst case load step will be from 3.75 A to 1.25 A. The output voltage increases during this load transition and the stated maximum in our specification is 4 % of the output voltage. This makes $V_f = 1.04 \times 3.3 \text{ V} = 3.43 \text{ V}$. V_i is the initial capacitor voltage which is the nominal output voltage of 3.3 V. Using these numbers in Equation 33 yields a minimum capacitance of 68 μF .

Equation 34 calculates the minimum output capacitance needed to meet the output voltage ripple specification, where f_{sw} is the switching frequency, $V_{ORIPPLE}$ is the maximum allowable output voltage ripple, and I_{RIPPLE} is the inductor ripple current. Equation 34 yields 30 μF .

Equation 35 calculates the maximum ESR an output capacitor can have to meet the output voltage ripple specification. Equation 35 indicates the equivalent ESR should be less than 10 $\text{m}\Omega$.

The most stringent criteria for the output capacitor is 95 μF required to maintain the output voltage within regulation tolerance during a load transient.

Capacitance de-ratings for aging, temperature and dc bias increases this minimum value. For this example, 2 x 100 μF , 6.3 V type X5R ceramic capacitors with 2 $\text{m}\Omega$ of ESR will be used. The derated capacitance is 130 μF , well above the minimum required capacitance of 95 μF .

Capacitors are generally rated for a maximum ripple current that can be filtered without degrading capacitor reliability, especially non ceramic capacitors. Some capacitor data sheets specify the Root Mean Square (RMS) value of the maximum ripple current. Equation 36 can be used to calculate the RMS ripple current that the output capacitor must support. For this example, Equation 36 yields 460 mA.

$$C_{OUT} > \frac{2 \times \Delta I_{OUT}}{f_{SW} \times \Delta V_{OUT}} = \frac{2 \times 2.5 \text{ A}}{400 \text{ kHz} \times 0.13 \text{ V}} = 95 \mu\text{F} \quad (32)$$

$$C_{OUT} > L_O \times \frac{\left((I_{OH})^2 - (I_{OL})^2 \right)}{\left((V_f)^2 - (V_i)^2 \right)} = 4.8 \mu\text{H} \times \frac{\left(3.75 \text{ A}^2 - 1.25 \text{ A}^2 \right)}{\left(3.43 \text{ V}^2 - 3.3 \text{ V}^2 \right)} = 68 \mu\text{F} \quad (33)$$

$$C_{OUT} > \frac{1}{8 \times f_{SW}} \times \frac{1}{\left(\frac{V_{ORIPPLE}}{I_{RIPPLE}} \right)} = \frac{1}{8 \times 400 \text{ kHz}} \times \frac{1}{\left(\frac{16 \text{ mV}}{1.58 \text{ A}} \right)} = 30 \mu\text{F} \quad (34)$$

$$R_{ESR} < \frac{V_{ORIPPLE}}{I_{RIPPLE}} = \frac{16 \text{ mV}}{1.58 \text{ A}} = 10 \text{ m}\Omega \quad (35)$$

$$I_{\text{COUT(rms)}} = \frac{V_{\text{OUT}} \times (V_{\text{IN(max)}} - V_{\text{OUT}})}{\sqrt{12} \times V_{\text{IN(max)}} \times L_{\text{O}} \times f_{\text{SW}}} = \frac{3.3 \text{ V} \times (42 \text{ V} - 3.3 \text{ V})}{\sqrt{12} \times 42 \text{ V} \times 4.8 \mu\text{H} \times 400 \text{ kHz}} = 460 \text{ mA} \quad (36)$$

8.2.2.5 Catch Diode

The TPS54540 requires an external catch diode between the SW terminal and GND. The selected diode must have a reverse voltage rating equal to or greater than $V_{\text{IN(max)}}$. The peak current rating of the diode must be greater than the maximum inductor current. Schottky diodes are typically a good choice for the catch diode due to their low forward voltage. The lower the forward voltage of the diode, the higher the efficiency of the regulator.

Typically, diodes with higher voltage and current ratings have higher forward voltages. A diode with a minimum of 42 V reverse voltage is preferred to allow input voltage transients up to the rated voltage of the TPS54540.

For the example design, the PDS760-13 Schottky diode is selected for its lower forward voltage and good thermal characteristics compared to smaller devices. The typical forward voltage of the PDS760-13 is 0.52 volts at 5 A and 25°C.

The diode must also be selected with an appropriate power rating. The diode conducts the output current during the off-time of the internal power switch. The off-time of the internal switch is a function of the maximum input voltage, the output voltage, and the switching frequency. The output current during the off-time is multiplied by the forward voltage of the diode to calculate the instantaneous conduction losses of the diode. At higher switching frequencies, the ac losses of the diode need to be taken into account. The ac losses of the diode are due to the charging and discharging of the junction capacitance and reverse recovery charge. Equation 37 is used to calculate the total power dissipation, including conduction losses and ac losses of the diode.

The PDS760-13 diode has a junction capacitance of 300 pF. Using Equation 37, the total loss in the diode at the nominal input voltage is 1.9 W.

If the power supply spends a significant amount of time at light load currents or in sleep mode, consider using a diode which has a low leakage current and slightly higher forward voltage drop.

$$P_{\text{D}} = \frac{(V_{\text{IN(max)}} - V_{\text{OUT}}) \times I_{\text{OUT}} \times V_{\text{fd}}}{V_{\text{IN}}} + \frac{C_{\text{j}} \times f_{\text{SW}} \times (V_{\text{IN}} + V_{\text{fd}})^2}{2} = \frac{(12 \text{ V} - 3.3 \text{ V}) \times 5 \text{ A} \times 0.52 \text{ V}}{12 \text{ V}} + \frac{300 \text{ pF} \times 400 \text{ kHz} \times (12 \text{ V} + 0.52 \text{ V})^2}{2} = 1.9 \text{ W} \quad (37)$$

8.2.2.6 Input Capacitor

The TPS54540 requires a high quality ceramic type X5R or X7R input decoupling capacitor with at least 3 μF of effective capacitance. Some applications will benefit from additional bulk capacitance. The effective capacitance includes any loss of capacitance due to dc bias effects. The voltage rating of the input capacitor must be greater than the maximum input voltage. The capacitor must also have a ripple current rating greater than the maximum input current ripple of the TPS54540. The input ripple current can be calculated using Equation 38.

The value of a ceramic capacitor varies significantly with temperature and the dc bias applied to the capacitor. The capacitance variations due to temperature can be minimized by selecting a dielectric material that is more stable over temperature. X5R and X7R ceramic dielectrics are usually selected for switching regulator capacitors because they have a high capacitance to volume ratio and are fairly stable over temperature. The input capacitor must also be selected with consideration for the dc bias. The effective value of a capacitor decreases as the dc bias across a capacitor increases.

For this example design, a ceramic capacitor with at least a 42 V voltage rating is required to support transients up to the maximum input voltage. Common standard ceramic capacitor voltage ratings include 4 V, 6.3 V, 10 V, 16 V, 25 V, 50 V or 100 V. For this example, four 4.7 μF, 50 V capacitors in parallel are used. Table 2 shows several choices of high voltage capacitors.

The input capacitance value determines the input ripple voltage of the regulator. The maximum input voltage ripple occurs at 50% duty cycle and can be calculated using Equation 39. Using the design example values, $I_{\text{OUT}} = 5 \text{ A}$, $C_{\text{IN}} = 18.8 \mu\text{F}$, $f_{\text{sw}} = 400 \text{ kHz}$, yields an input voltage ripple of 170 mV and a rms input ripple current of 2.5 A.

$$I_{CI(rms)} = I_{OUT} \times \sqrt{\frac{V_{OUT}}{V_{IN(min)}} \times \frac{(V_{IN(min)} - V_{OUT})}{V_{IN(min)}}} = 5 \text{ A} \times \sqrt{\frac{3.3 \text{ V}}{6 \text{ V}} \times \frac{(6 \text{ V} - 3.3 \text{ V})}{6 \text{ V}}} = 2.5 \text{ A} \quad (38)$$

$$\Delta V_{IN} = \frac{I_{OUT} \times 0.25}{C_{IN} \times f_{SW}} = \frac{5 \text{ A} \times 0.25}{18.8 \mu\text{F} \times 400 \text{ kHz}} = 170 \text{ mV} \quad (39)$$

Table 2. Capacitor Types

VALUE (μF)	EIA Size	VOLTAGE	DIELECTRIC	COMMENTS
1 to 2.2	1210	100 V	X7R	GRM32 series
1 to 4.7		50 V		
1	1206	100 V		GRM31 series
1 to 2.2		50 V		
1 to 1.8	2220	50 V		VJ X7R series

1 to 3.9	2225	50 V		
1 to 1.8		100 V		
1 to 2.2	1812	100 V		C series C4532
1.5 to 6.8		50 V		
1 to 2.2	1210	100 V		C series C3225
1 to 3.3		50 V		
1 to 4.7	1210	50 V		X7R dielectric series
1		100 V		
1 to 4.7	1812	50 V		
1 to 2.2		100 V		

8.2.2.7 Bootstrap Capacitor Selection

A 0.1-μF ceramic capacitor must be connected between the BOOT and SW terminals for proper operation. A ceramic capacitor with X5R or better grade dielectric is recommended. The capacitor should have a 10 V or higher voltage rating.

8.2.2.8 Undervoltage Lockout Set Point

The Undervoltage Lockout (UVLO) can be adjusted using an external voltage divider on the EN terminal of the TPS54540. The UVLO has two thresholds, one for power up when the input voltage is rising and one for power down or brown outs when the input voltage is falling. For the example design, the supply should turn on and start switching once the input voltage increases above 5.75 V (UVLO start). After the regulator starts switching, it should continue to do so until the input voltage falls below 4.5 V (UVLO stop).

Programmable UVLO threshold voltages are set using the resistor divider of R_{UVLO1} and R_{UVLO2} between V_{IN} and ground connected to the EN terminal. Equation 4 and Equation 5 calculate the resistance values necessary. For the example application, a 365 kΩ between V_{IN} and EN (R_{UVLO1}) and a 88.7 kΩ between EN and ground (R_{UVLO2}) are required to produce the 5.75 V and 4.5 V start and stop voltages.

$$R_{UVLO1} = \frac{V_{START} - V_{STOP}}{I_{HYS}} = \frac{5.75 \text{ V} - 4.5 \text{ V}}{3.4 \mu\text{A}} = 368 \text{ k}\Omega \quad (40)$$

$$R_{UVLO2} = \frac{V_{ENA}}{\frac{V_{START} - V_{ENA}}{R_{UVLO1}} + I_1} = \frac{1.2 \text{ V}}{\frac{5.75 \text{ V} - 1.2 \text{ V}}{365 \text{ k}\Omega} + 1.2 \mu\text{A}} = 88.7 \text{ k}\Omega \quad (41)$$

8.2.2.9 Output Voltage and Feedback Resistors Selection

The voltage divider of R5 and R6 sets the output voltage. For the example design, 10.2 kΩ was selected for R6. Using Equation 3, R5 is calculated as 31.9 kΩ. The nearest standard 1% resistor is 31.6 kΩ. Due to the input current of the FB terminal, the current flowing through the feedback network should be greater than 1 μA to maintain the output voltage accuracy. This requirement is satisfied if the value of R6 is less than 800 kΩ. Choosing higher resistor values decreases quiescent current and improves efficiency at low output currents but may also introduce noise immunity problems.

$$R_{HS} = R_{LS} \times \frac{V_{OUT} - 0.8 \text{ V}}{0.8 \text{ V}} = 10.2 \text{ k}\Omega \times \left(\frac{3.3 \text{ V} - 0.8 \text{ V}}{0.8 \text{ V}} \right) = 31.9 \text{ k}\Omega \quad (42)$$

8.2.2.10 Minimum V_{IN}

To ensure proper operation of the device and to keep the output voltage in regulation, the input voltage at the device must be above the value calculated with Equation 43. Using the typical values for the R_{HS} , R_{DC} and V_F in this application example, the minimum input voltage is 5.56 V. The BOOT-SW = 3 V curve in Figure 1 was used for $R_{DS(on)} = 0.12 \Omega$ because the device operates with low drop out. When operating with low dropout, the BOOT-SW voltage is regulated at a lower voltage because the BOOT-SW capacitor is not refreshed every switching cycle. In the final application, the values of $R_{DS(on)}$, R_{dc} and V_F used in this equation must include tolerance of the component specifications and the variation of these specifications at their maximum operating temperature in the application. In this application example, the calculated minimum input voltage is near the input voltage UVLO for the TPS54540 so the device may turn off before going into drop out.

$$V_{IN(min)} = \frac{V_{OUT} + V_F + R_{dc} \times I_{OUT}}{0.99} + R_{DS(on)} \times I_{OUT} - V_F$$

$$V_{IN(min)} = \frac{3.3 \text{ V} + 0.5 \text{ V} + 0.0103 \Omega \times 5 \text{ A}}{0.99} + 0.12 \Omega \times 5 \text{ A} - 0.5 \text{ V} = 3.99 \text{ V} \quad (43)$$

8.2.2.11 Compensation

There are several methods to design compensation for DC-DC regulators. The method presented here is easy to calculate and ignores the effects of the slope compensation that is internal to the device. Since the slope compensation is ignored, the actual crossover frequency will be lower than the crossover frequency used in the calculations. This method assumes the crossover frequency is between the modulator pole and the ESR zero and the ESR zero is at least 10 times greater the modulator pole.

To get started, the modulator pole, $f_{p(mod)}$, and the ESR zero, f_{z1} must be calculated using Equation 44 and Equation 45. For C_{OUT} , use a derated value of 130 μF. Use equations Equation 46 and Equation 47 to estimate a starting point for the crossover frequency, f_{co} . For the example design, $f_{p(mod)}$ is 1850 Hz and $f_{z(mod)}$ is 610 kHz. Equation 45 is the geometric mean of the modulator pole and the ESR zero and Equation 47 is the mean of modulator pole and half of the switching frequency. Equation 46 yields 34 kHz and Equation 47 gives 19 kHz. Use the geometric mean value of Equation 46 and Equation 47 for an initial crossover frequency. For this example, after lab measurement, the crossover frequency target was increased to 30 kHz for an improved transient response.

Next, the compensation components are calculated. A resistor in series with a capacitor is used to create a compensating zero. A capacitor in parallel to these two components forms the compensating pole.

$$f_{P(mod)} = \frac{I_{OUT(max)}}{2 \times \pi \times V_{OUT} \times C_{OUT}} = \frac{5 \text{ A}}{2 \times \pi \times 3.3 \text{ V} \times 130 \mu\text{F}} = 1850 \text{ Hz} \quad (44)$$

$$f_{Z(mod)} = \frac{1}{2 \times \pi \times R_{ESR} \times C_{OUT}} = \frac{1}{2 \times \pi \times 1 \text{ m}\Omega \times 130 \mu\text{F}} = 610 \text{ kHz} \quad (45)$$

$$f_{co1} = \sqrt{f_{p(mod)} \times f_{z(mod)}} = \sqrt{1850 \text{ Hz} \times 610 \text{ kHz}} = 34 \text{ kHz} \quad (46)$$

$$f_{co2} = \sqrt{f_{p(mod)} \times \frac{f_{SW}}{2}} = \sqrt{1850 \text{ Hz} \times \frac{400 \text{ kHz}}{2}} = 19 \text{ kHz} \quad (47)$$

To determine the compensation resistor, R4, use Equation 48. The typical power stage transconductance, g_{mps} , is 17 A/V. The output voltage, V_{O} , reference voltage, V_{REF} , and amplifier transconductance, g_{mea} , are 3.3 V, 0.8 V and 350 μ A/V, respectively. R4 is calculated to be 17 k Ω and a standard value of 16.9 k Ω is selected. Use Equation 49 to set the compensation zero to the modulator pole frequency. Equation 49 yields 5100 pF for compensating capacitor C5. 4700 pF is used for this design.

$$R4 = \left(\frac{2 \times \pi \times f_{co} \times C_{OUT}}{g_{mps}} \right) \times \left(\frac{V_{OUT}}{V_{REF} \times g_{mea}} \right) = \left(\frac{2 \times \pi \times 30 \text{ kHz} \times 130 \mu\text{F}}{17 \text{ A/V}} \right) \times \left(\frac{3.3\text{V}}{0.8 \text{ V} \times 350 \mu\text{A/V}} \right) = 17 \text{ k}\Omega \quad (48)$$

$$C5 = \frac{1}{2 \times \pi \times R4 \times f_{p(mod)}} = \frac{1}{2 \times \pi \times 16.9 \text{ k}\Omega \times 1850 \text{ Hz}} = 5100 \text{ pF} \quad (49)$$

A compensation pole can be implemented if desired by adding capacitor C8 in parallel with the series combination of R4 and C5. Use the larger value calculated from Equation 50 and Equation 51 for C8 to set the compensation pole. The selected value of C8 is 47 pF for this design example.

$$C8 = \frac{C_{OUT} \times R_{ESR}}{R4} = \frac{130 \mu\text{F} \times 1 \text{ m}\Omega}{16.9 \text{ k}\Omega} = 15 \text{ pF} \quad (50)$$

$$C8 = \frac{1}{R4 \times f_{sw} \times \pi} = \frac{1}{16.9 \text{ k}\Omega \times 400 \text{ kHz} \times \pi} = 47 \text{ pF} \quad (51)$$

8.2.2.12 Discontinuous Conduction Mode and Eco-mode Boundary

With an input voltage of 12 V, the power supply enters discontinuous conduction mode when the output current is less than 560 mA. The power supply enters Eco-mode when the output current is lower than 18 mA. The input current draw is 241 μ A with no load.

8.2.2.13 Power Dissipation Estimate

The following formulas show how to estimate the TPS54540 power dissipation under continuous conduction mode (CCM) operation. These equations should not be used if the device is operating in discontinuous conduction mode (DCM).

The power dissipation of the IC includes conduction loss (P_{COND}), switching loss (P_{SW}), gate drive loss (P_{GD}) and supply current (P_Q). Example calculations are shown with the 12 V typical input voltage of the design example.

$$P_{COND} = (I_{OUT})^2 \times R_{DS(on)} \times \left(\frac{V_{OUT}}{V_{IN}} \right) = 5 \text{ A}^2 \times 92 \text{ m}\Omega \times \frac{3.3 \text{ V}}{12 \text{ V}} = 0.633 \text{ W} \quad (52)$$

$$P_{SW} = V_{IN} \times f_{SW} \times I_{OUT} \times t_{rise} = 12 \text{ V} \times 400 \text{ kHz} \times 5 \text{ A} \times 4.9 \text{ ns} = 0.118 \text{ W} \quad (53)$$

$$P_{GD} = V_{IN} \times Q_G \times f_{SW} = 12 \text{ V} \times 3 \text{ nC} \times 400 \text{ kHz} = 0.014 \text{ W} \quad (54)$$

$$P_Q = V_{IN} \times I_Q = 12 \text{ V} \times 146 \mu\text{A} = 0.0018 \text{ W} \quad (55)$$

Where:

I_{OUT} is the output current (A).

$R_{DS(on)}$ is the on-resistance of the high-side MOSFET (Ω).

V_{OUT} is the output voltage (V).

V_{IN} is the input voltage (V).

f_{sw} is the switching frequency (Hz).

t_{rise} is the SW terminal voltage rise time and can be estimated by $t_{rise} = V_{IN} \times 0.16 \text{ ns/V} + 3 \text{ ns}$

Q_G is the total gate charge of the internal MOSFET

I_Q is the operating nonswitching supply current

Therefore,

$$P_{TOT} = P_{COND} + P_{SW} + P_{GD} + P_Q = 0.633 \text{ W} + 0.118 \text{ W} + 0.014 \text{ W} + 0.0018 \text{ W} = 0.77 \text{ W} \quad (56)$$

For given T_A ,

$$T_J = T_A + R_{TH} \times P_{TOT} \quad (57)$$

For given $T_{JMAX} = 150^\circ\text{C}$

$$T_{A(max)} = T_{J(max)} - R_{TH} \times P_{TOT} \quad (58)$$

Where:

- Ptot** is the total device power dissipation (W).
- T_A** is the ambient temperature (°C).
- T_J** is the junction temperature (°C).
- R_{TH}** is the thermal resistance of the package (°C/W)
- T_{JMAX}** is maximum junction temperature (°C).
- T_{AMAX}** is maximum ambient temperature (°C).

There will be additional power losses in the regulator circuit due to the inductor ac and dc losses, the catch diode and PCB trace resistance impacting the overall efficiency of the regulator.

8.2.3 Application Curves

Measurements are taken with standard EVM using a 12 V input, 3.3 V output, and 5 A load unless otherwise noted.

9 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 4.5 V and 42 V. This input supply should be well regulated. If the input supply is located more than a few inches from the TPS54540 converter additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic capacitor with a value of 100 μ F is a typical choice.

10 Layout

10.1 Safe Operating Area

The safe operating area (SOA) of the device is shown in Figure 54, through Figure 57 for 3.3 V, 5 V and 12 V outputs and varying amounts of forced air flow. The temperature derating curves represent the conditions at which the internal and external components are at or below the manufacturer's maximum operating temperatures. Derating limits apply to devices soldered directly to a double-sided PCB with 2 oz. copper, similar to the EVM. Careful attention must be paid to the other components chosen for the design, especially the catch diode. In most of these test conditions, the thermal performance is limited by the catch diode. When operating at high duty cycles or at higher switching frequency the TPS54540's thermal performance can become the limiting factor.

10.2 Layout Guidelines

Layout is a critical portion of good power supply design. There are several signal paths that conduct fast changing currents or voltages that can interact with stray inductance or parasitic capacitance to generate noise or degrade performance.

- To reduce parasitic effects, the VIN terminal should be bypassed to ground with a low ESR ceramic bypass capacitor with X5R or X7R dielectric.
- Care should be taken to minimize the loop area formed by the bypass capacitor connections, the VIN terminal, and the anode of the catch diode.
- The GND terminal should be tied directly to the power pad under the IC and the PowerPAD™.
- The power pad should be connected to internal PCB ground planes using multiple vias directly under the IC.
- The SW terminal should be routed to the cathode of the catch diode and to the output inductor.
- Since the SW connection is the switching node, the catch diode and output inductor should be located close to the SW terminals, and the area of the PCB conductor minimized to prevent excessive capacitive coupling.
- For operation at full rated load, the top side ground area must provide adequate heat dissipating area.
- The RT/CLK terminal is sensitive to noise so the RT resistor should be located as close as possible to the IC and routed with minimal lengths of trace.
- The additional external components can be placed approximately as shown.
- It may be possible to obtain acceptable performance with alternate PCB layouts, however this layout has been shown to produce good results and is meant as a guideline.

10.3 Layout Example

Figure 58. PCB Layout Example

10.3.1 Estimated Circuit Area

Boxing in the components in the design of [Figure 35](#) the estimated printed circuit board area is 1.025 in² (661 mm²). This area does not include test points or connectors.

11 器件和文档支持

11.1 使用 WEBENCH® 工具定制设计方案

请单击[此处](#)，借助 WEBENCH®电源设计器并使用 TPS54540 器件创建定制设计方案。

1. 首先输入您的 V_{IN} 、 V_{OUT} 和 I_{OUT} 要求。
2. 使用优化器拨盘可优化效率、封装和成本等关键设计参数并将您的设计与德州仪器 (TI) 的其他可行解决方案进行比较。
3. WEBENCH Power Designer 提供一份定制原理图以及罗列实时价格和组件可用性的物料清单。
4. 在多数情况下，您还可以：
 - 运行电气仿真，观察重要波形以及电路性能
 - 运行热性能仿真，了解电路板热性能
 - 将定制原理图和布局方案导出至常用 CAD 格式
 - 打印设计方案的 PDF 报告并与同事共享
5. 有关 WEBENCH 工具的详细信息，请访问 www.ti.com/WEBENCH。

11.2 接收文档更新通知

如需接收文档更新通知，请访问 www.ti.com.cn 网站上的器件产品文件夹。点击右上角的提醒我 (Alert me) 注册后，即可每周定期收到已更改的产品信息。有关更改的详细信息，请查阅已修订文档中包含的修订历史记录。

11.3 社区资源

12 机械、封装和可订购信息

以下页中包括机械、封装和可订购信息。这些信息是针对指定器件可提供的最新数据。这些数据会在无通知且不对本文档进行修订的情况下发生改变。欲获得该数据表的浏览器版本，请查阅左侧的导航栏。

PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead/Ball Finish (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
TPS54540DDA	ACTIVE	SO PowerPAD	DDA	8	75	Green (RoHS & no Sb/Br)	CU NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	54540	Samples
TPS54540DDAR	ACTIVE	SO PowerPAD	DDA	8	2500	Green (RoHS & no Sb/Br)	CU NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	54540	Samples

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBsolete: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

PowerPAD™ PLASTIC SMALL-OUTLINE

- NOTES:
- A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5-1994.
 - B. This drawing is subject to change without notice.
 - C. Body dimensions do not include mold flash or protrusion not to exceed 0,15.
 - D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 for information regarding recommended board layout. This document is available at www.ti.com <<http://www.ti.com>>.
 - E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
 - F. This package complies to JEDEC MS-012 variation BA

PowerPAD is a trademark of Texas Instruments.

DDA (R-PDSO-G8)

PowerPAD™ PLASTIC SMALL OUTLINE

THERMAL INFORMATION

This PowerPAD™ package incorporates an exposed thermal pad that is designed to be attached to a printed circuit board (PCB). The thermal pad must be soldered directly to the PCB. After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For additional information on the PowerPAD package and how to take advantage of its heat dissipating abilities, refer to Technical Brief, PowerPAD Thermally Enhanced Package, Texas Instruments Literature No. SLMA002 and Application Brief, PowerPAD Made Easy, Texas Instruments Literature No. SLMA004. Both documents are available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

Exposed Thermal Pad Dimensions

4208951-6/D 04/12

- NOTES:
- A. All linear dimensions are in millimeters.
 - B. This drawing is subject to change without notice.
 - C. Publication IPC-7351 is recommended for alternate designs.
 - D. This package is designed to be soldered to a thermal pad on the board. Refer to Technical Brief, PowerPad Thermally Enhanced Package, Texas Instruments Literature No. SLMA002, SLMA004, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <<http://www.ti.com>>. Publication IPC-7351 is recommended for alternate designs.
 - E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Example stencil design based on a 50% volumetric metal load solder paste. Refer to IPC-7525 for other stencil recommendations.
 - F. Customers should contact their board fabrication site for solder mask tolerances between and around signal pads.

PowerPAD is a trademark of Texas Instruments.

重要声明

德州仪器 (TI) 公司有权按照最新发布的 JESD46 对其半导体产品和服务进行纠正、增强、改进和其他修改，并不再按最新发布的 JESD48 提供任何产品和服务。买方在下订单前应获取最新的相关信息，并验证这些信息是否完整且是最新的。

TI 公布的半导体产品销售条款 (<http://www.ti.com/sc/docs/stdterms.htm>) 适用于 TI 已认证和批准上市的已封装集成电路产品的销售。另有其他条款可能适用于其他类型 TI 产品及服务的使用或销售。

复制 TI 数据表上 TI 信息的重要部分时，不得变更该等信息，且必须随附所有相关保证、条件、限制和通知，否则不得复制。TI 对该等复制文件不承担任何责任。第三方信息可能受到其它限制条件的制约。在转售 TI 产品或服务时，如果存在对产品或服务参数的虚假陈述，则会失去相关 TI 产品或服务的明示或暗示保证，且构成不公平的、欺诈性商业行为。TI 对此类虚假陈述不承担任何责任。

买方和在系统中整合 TI 产品的其他开发人员（总称“设计人员”）理解并同意，设计人员在设计应用时应自行实施独立的分析、评价和判断，且应全权负责并确保应用的安全性，及设计人员的应用（包括应用中使用的 TI 产品）应符合所有适用的法律法规及其他相关要求。设计人员就自己设计的应用声明，其具备制订和实施下列保障措施所需的一切必要专业知识，能够 (1) 预见故障的危险后果，(2) 监视故障及其后果，以及 (3) 降低可能导致危险的故障几率并采取适当措施。设计人员同意，在使用或分发包含 TI 产品的任何应用前，将彻底测试该等应用和该等应用中所用 TI 产品的功能。

TI 提供技术、应用或其他设计建议、质量特点、可靠性数据或其他服务或信息，包括但不限于与评估模块有关的参考设计和材料（总称“TI 资源”），旨在帮助设计人员开发整合了 TI 产品的应用，如果设计人员（个人，或如果是代表公司，则为设计人员的公司）以任何方式下载、访问或使用任何特定的 TI 资源，即表示其同意仅为该等目标，按照本通知的条款使用任何特定 TI 资源。

TI 所提供的 TI 资源，并未扩大或以其他方式修改 TI 对 TI 产品的公开适用的质保及质保免责声明；也未导致 TI 承担任何额外的义务或责任。TI 有权对其 TI 资源进行纠正、增强、改进和其他修改。除特定 TI 资源的公开文档中明确列出的测试外，TI 未进行任何其他测试。

设计人员只有在开发包含该等 TI 资源所列 TI 产品的应用时，才被授权使用、复制和修改任何相关单项 TI 资源。但并未依据禁止反言原则或其他法理授予您任何 TI 知识产权的任何其他明示或默示的许可，也未授予您 TI 或第三方的任何技术或知识产权的许可，该等产权包括但不限于任何专利权、版权、屏蔽作品权或与美国 TI 产品或服务的任何整合、机器制作、流程相关的其他知识产权。涉及或参考了第三方产品或服务的信息不构成使用此类产品或服务的许可或与其相关的保证或认可。使用 TI 资源可能需要您向第三方获得对该等第三方专利或其他知识产权的许可。

TI 资源系“按原样”提供。TI 兹免除对资源及其使用作出所有其他明确或默示的保证或陈述，包括但不限于对准确性或完整性、产权保证、无屡发故障保证，以及适销性、适合特定用途和不侵犯任何第三方知识产权的任何默认保证。TI 不负责任何申索，包括但不限于因组合产品所致或与之有关的申索，也不为或对设计人员进行辩护或赔偿，即使该等产品组合已列于 TI 资源或其他地方。对因 TI 资源或其使用引起或与之有关的任何实际的、直接的、特殊的、附带的、间接的、惩罚性的、偶发的、从属或惩戒性损害赔偿，不管 TI 是否获悉可能会产生上述损害赔偿，TI 概不负责。

除 TI 已明确指出特定产品已达到特定行业标准（例如 ISO/TS 16949 和 ISO 26262）的要求外，TI 不对未达到任何该等行业标准要求而承担任何责任。

如果 TI 明确宣称产品有助于功能安全或符合行业功能安全标准，则该等产品旨在帮助客户设计和创作自己的符合相关功能安全标准和要求的的应用。在应用内使用产品的行为本身不会配有安全特性。设计人员必须确保遵守适用于其应用的相关安全要求和标准。设计人员不可将任何 TI 产品用于关乎性命的医疗设备，除非已由各方获得授权的管理人员签署专门的合同对此类应用专门作出规定。关乎性命的医疗设备是指出现故障会导致严重身体伤害或死亡的医疗设备（例如生命保障设备、心脏起搏器、心脏除颤器、人工心脏泵、神经刺激器以及植入设备）。此类设备包括但不限于，美国食品药品监督管理局认定为 III 类设备的设备，以及在美国以外的其他国家或地区认定为同等类别设备的所有医疗设备。

TI 可能明确指定某些产品具备某些特定资格（例如 Q100、军用级或增强型产品）。设计人员同意，其具备一切必要专业知识，可以为自己的应用选择适合的产品，并且正确选择产品的风险由设计人员承担。设计人员单方面负责遵守与该等选择有关的所有法律或监管要求。

设计人员同意向 TI 及其代表全额赔偿因其不遵守本通知条款和条件而引起的任何损害、费用、损失和/或责任。
