

Precision Analog Microcontroller, 16-Bit Analog Input/Output with MDIO Interface, Arm Cortex-M33

Data Sheet

ADuCM410

FEATURES

Analog input/output

- Multichannel, 16-bit, 2 MSPS ADC
- Up to 16 external channels
- On-chip die temperature monitor
- 4 power monitor channels
- 4 PGA/TIA channels supporting voltage and current measurements
- Fully differential and single-ended modes
- 0 V to VREF analog input range
- 12-bit voltage output DACs
 - 8× 0 V to 2.5 V, 1 kΩ load
 - 4× 0 V to 2.5 V, 2.5 kΩ load
- On-chip low drift voltage reference, 1.25 V or 2.5 V
 - Buffered 1.25 V or 2.5 V output
- 4 voltage comparators

Microcontroller

- 32-bit Arm Cortex-M33 core, 32-bit RISC architecture, FPU
- Serial wire port supports code download and debug

Clocking options

- 16 MHz on-chip oscillator
- 160 MHz PLL output with programmable divider
- External clock source

Memory

- 2× 512 kB independent Flash/EE memories
 - 10,000 cycles Flash/EE endurance
 - 10-year Flash/EE retention
- 128 kB SRAM with ECC

Software triggered, in circuit reprogrammability via MDIO or I²C

On-chip peripherals

- 2× UART, 3× SPI, 3× I²C serial input/output
- Multilevel voltage (3.3 V, 1.8 V, 1.2 V) GPIOs
- MDIO slave up to 10 MHz
- 5× general-purpose timers
- Wake-up timer (WUTs)
- Watchdog timers (WDTs)
- 32-element PLA
- 16-bit PWM
- 10 external interrupts

Power

- Multiple supplies: 3.3 V for voltage DACs and ADCs, and 3.3 V, 1.8 V, or 1.2 V for digital inputs/outputs

Flexible operating modes for low power applications

Packages and temperature range

- 5 mm × 5 mm, 81-ball CSP_BGA and 3.46 mm × 3.46 mm 64-ball WLCS
- BGA package uses ULA molding compounds

Fully specified for –40°C to +105°C operation

Tools

- Low cost quick start development system
- Full third-party support

APPLICATIONS

- Optical networking 100 Gbps/200 Gbps/400 Gbps and higher frequency modules
- Industrial control, automation, and instrumentation systems

GENERAL DESCRIPTION

The ADuCM410 is a fully integrated, single package device that includes high performance analog peripherals together with digital peripherals (controlled by a 160 MHz Arm[®] Cortex[™]-M33 processor) and integrated flash for code and data.

The analog-to-digital converter (ADC) on the ADuCM410 provides 16-bit, 2 MSPS data acquisition using up to 16 input pins that can be programmed for single-ended or differential operation with a programmable gain amplifier (PGA) or transimpedance amplifier (TIA) for voltage and current measurements. Additionally, the die temperature and supply voltages can be measured.

The ADC input voltage is 0 V to VREF. A sequencer is provided that allows a user to select a set of ADC channels to be measured in sequence without software involvement during the sequence. The sequence can optionally repeat automatically at a user selectable rate.

Up to 12 channels of 12-bit voltage digital-to-analog converters (VDACs) are provided with output buffers supported.

The ADuCM410 can be configured so that the digital and analog outputs retain their output voltages through a watchdog or software reset sequence. Therefore, a product can remain functional even while the ADuCM410 is resetting itself.

The ADuCM410 has a low power ARM Cortex-M33 processor and a 32-bit reduced instruction set computer (RISC) machine that offers up to 240 MIPS peak performance with a floating-point unit (FPU). Also integrated are 2× 512 kB Flash/EE memory and 128 kB static random access memory (SRAM)—both with single-error correction (SEC) and double error detection (DED) error checking and correction (ECC). The flash comprises two separate 512 kB blocks supporting execution from one flash block and simultaneous writing and/or erasing of the other flash block.

REVISION HISTORY

9/2020—Revision 0: Initial Version

The ADuCM410 operates from an on-chip oscillator and has a phase-locked loop (PLL) of 160 MHz. This clock can optionally be divided down to reduce current consumption. Additional low power modes can be set via the ADuCM410 software.

The device includes a management data input/output (MDIO) interface capable of operating up to 10 MHz. User programming is eased by incorporating physical address (PHYADR) and device address (DEVAD) hardware comparators. The nonerasable kernel code combined with flags in user flash allow user code to reliably switch between the two hardware independent flash blocks.

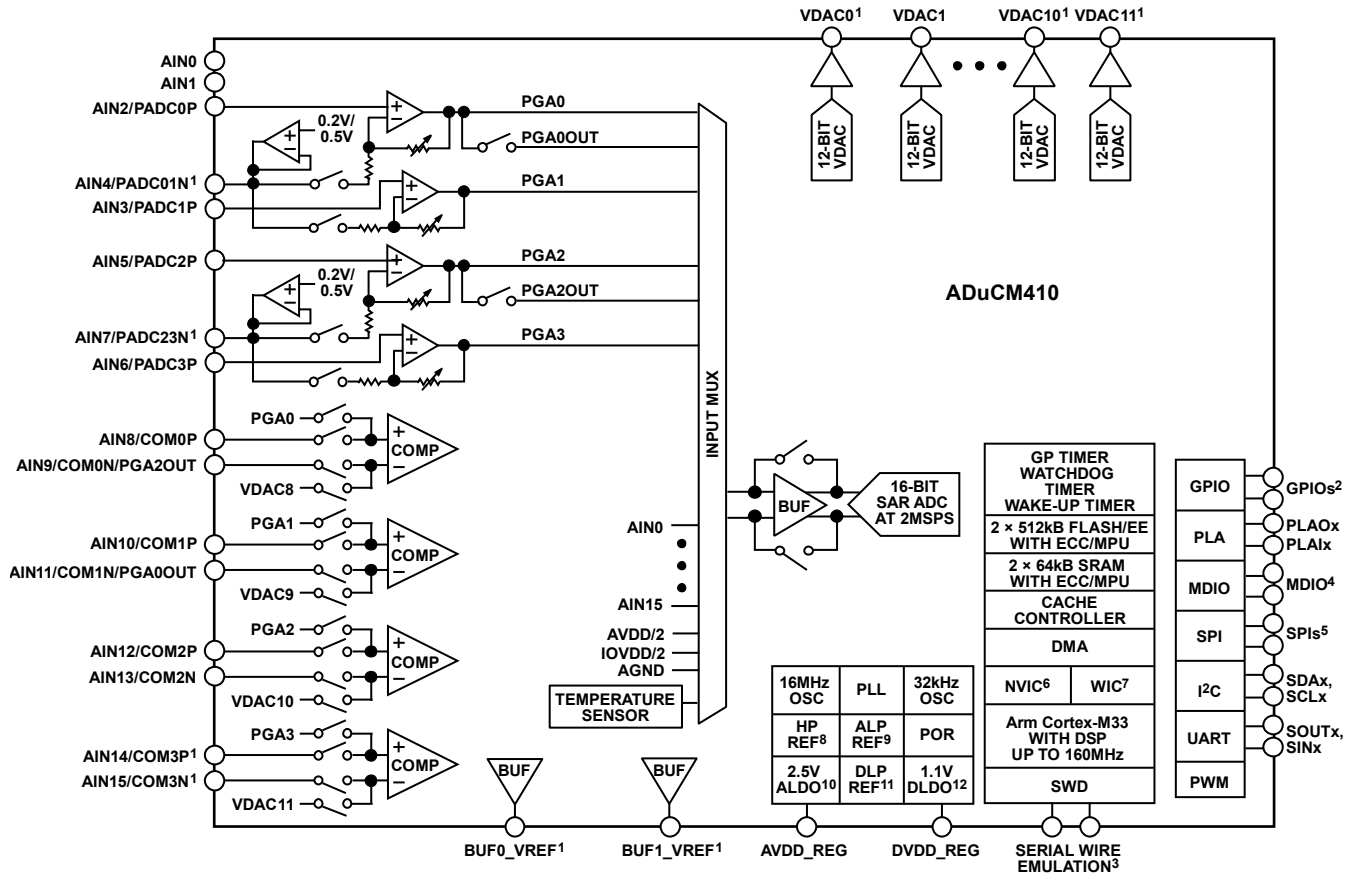

The ADuCM410 integrates a range of on-chip peripherals that can be configured under software control, as required in the application. These peripherals include 2× universal asynchronous receiver transmitter (UART), 3× I²C, and 3× serial peripheral interface (SPI) serial input/output communication controllers, general-purpose inputs/outputs (GPIOs), 32-element programmable logic arrays (PLAs), five general-purpose timers, a wake-up timer (WUT), and a system watchdog timer (WDT). A 16-bit pulse-width modulation (PWM) with eight output channels is also provided.

The GPIO pins (Px.x) power up in high impedance input mode. In output mode, the software chooses between open-drain mode and push/pull mode. The pull-up and pull-down resistors can be disabled and enabled in the software. The GPIO pins can be configured with different voltage levels according to the IOVDDx pin, such as 3.3 V, 1.8 V, and 1.2 V. In GPIO output mode, the inputs can remain enabled to monitor the GPIO pins. The GPIO pins can also be programmed to handle digital or analog peripheral signals, in which case, the pin characteristics are matched to the specific requirement.

A large support ecosystem is available for the Arm Cortex-M33 processor to ease product development of the ADuCM410. Access is via the Arm serial wire debug port. On-chip factory firmware supports in-circuit serial download via MDIO or I²C. These features are incorporated into a low cost, quick start development system supporting this precision analog microcontroller.

Note that throughout this data sheet, multifunction pins, such as VDACC7/P4.2, are referred to either by the entire pin name or by a single function of the pin, for example, P4.2, when only that function is relevant.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

θ_{JA} is the natural convection junction to ambient thermal resistance measured in a one cubic foot sealed enclosure. θ_{JC} is the junction to case thermal resistance.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

The ADuCM410 is an on-chip system. The ADuCM410 is mixed-signal microcontroller based on the Arm Cortex-M33 processor.

See the [ADuCM410 hardware reference manual](#) for full details on the operation of the ADuCM410, including, but not limited

to, all register details and information about the various features and operation of the power management unit, the Arm Cortex-M33 processor, the ADC circuit, the flash controller, and the SPI, I²C, and UART interfaces.

RMS NOISE RESOLUTION OF ADC

The rms noise specifications for the ADC with different ADC digital filter settings are described in Table 14.

The internal 2.5 V reference was used for all measurements.

For gain = 1, single-ended measurements with $V_{IN} = 2$ V was used.

For PGA gains ≥ 2 , a differential input voltage was applied, ensuring the PGA output to the ADC was always 2 V. For example, for gain = 4, $V_{IN} = 500$ mV.

Table 15 shows the rms and peak-to-peak effective number of bits based on the noise results in Table 14 for various PGA gain

settings. Peak-to-peak effective bit results are shown in parentheses. RMS bits are calculated as follows:

$$\log\left(\frac{\text{Input Range}}{\text{RMS Noise}}\right)$$

Peak-to-peak bits are calculated as follows:

$$\log_2\left(\frac{\text{Input Range}}{6.6 \times \text{RMS Noise}}\right)$$

APPLICATIONS INFORMATION

POWER SUPPLIES

The ADuCM410 operational power supply voltage range is 2.85 V to 3.6 V for AVDD and IOVDD0.

IOVDD1 can be 1.2 V, 1.8 V, or the same as IOVDD0. The DVDD range is 1.8 V to 3.6 V.

Separate analog (AVDD) and digital power supply pins (IOVDD1 and DVDD) allow AVDD to be kept relatively free of noisy digital signals often present in the system DVDD line. In this mode, the ADuCM410 can also operate with split supplies. That is, the device can use different voltage levels for each supply (see Table 1). A typical split supply configuration is shown in Figure 16.

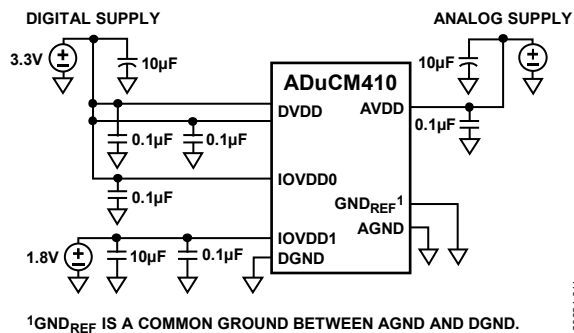

Figure 16. External Multiple Supply Connections

As an alternative to providing two separate power supplies, the user can reduce noise on AVDD by placing a small series resistor and/or ferrite bead between AVDD and DVDD, and then decouple AVDD separately to ground. An example of this configuration is shown in Figure 17. With this configuration, other analog circuitry (such as op amps and voltage reference) can be powered from the AVDD supply line as well.

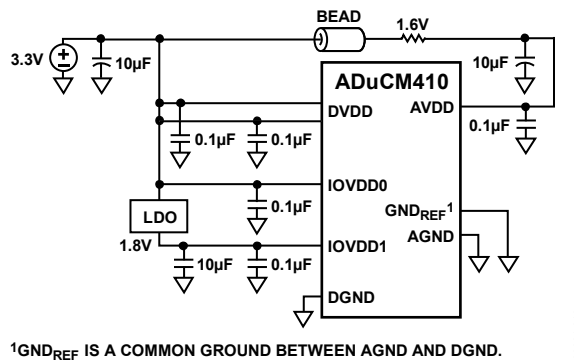

Figure 17. External Single-Supply Connections

In both Figure 16 and Figure 17, a large value (10 µF) reservoir capacitor is connected to DVDD, and a separate 10 µF capacitor is connected to AVDD. In addition, local small value (0.1 µF) capacitors are located at each AVDD, IOVDD0, IOVDD1, and DVDD pin of the chip. Include all recommended capacitors shown, and ensure that the smaller capacitors are close to each supply pin with trace lengths as short as possible. Connect the ground terminal of each of these capacitors directly to the underlying ground plane.

The analog and digital ground pins on the ADuCM410 must be referenced to the same system ground reference point.

POWER-UP REQUIREMENTS

Figure 18 and Figure 19 show the power-up requirements for DVDD and AVDD. Figure 20 shows the power-up requirement for IOVDD0 if no external pull-up is applied to the P2.3/BM/PLAI10 pin.

RECOMMENDED CIRCUIT AND COMPONENT VALUES

Figure 21 shows a typical connection diagram for the ADuCM410.

Adequately decouple the supplies and regulators with capacitors connected between the AVDD_REG, DVDD_REG, and IOVDDx balls and their associated ground balls (AGND and DGND). Table 12 and Table 13 indicate which ground balls are paired with which supply balls.

There are three digital supply balls, IOVDD0, IOVDD1, and DVDD. Decouple these balls with a 0.1 μF capacitor placed as near as possible to each of the three balls and their associated ground balls (DGND and AGND, respectively). In addition, place a 10 μF capacitor near these balls. For DVDD, to improve noise reduction, place a ferrite bead in series with a 10 μF capacitor to DGND.

Similarly, the analog supply pin (AVDD) requires a 0.1 μF capacitor placed as near as possible to each ball and its associated AGND ball. Also place a 10 μF capacitor near these balls.

The ADC reference requires a 4.7 μF capacitor be placed between ADCREFP and ADCREFN and located as near as possible to each ball. ADCREFN must be connected directly to AGND. The ADuCM410 contains two internal regulators. These regulators require external decoupling capacitors. The DVDD_REG and AVDD_REG balls each require a 0.47 μF capacitor to DGND and AGND, respectively. Take care in the layout to ensure that currents flowing from the ground end of each decoupling capacitor to its associated ground ball share as little track as possible with other ground currents on the PCB.
