Note: \* Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

### 16.3.8 Serial Port Register (SCSPTR)

SCSPTR is an 8-bit register that controls input/output and data for the ports multiplexed with the SCI function pins. Data to be output through the TXD pin can be specified to control break of serial transfer. Through bits 3 and 2, data reading and writing through the SCK pin can be specified. Bit 7 enables or disables RXI interrupts. The CPU can always read and write to SCSPTR. When reading the value on the SCI pins, use the respective port register. For details, refer to section 23, I/O Ports.

### 16.3.9 Serial Direction Control Register (SCSDCR)

The DIR bit in the serial direction control register (SCSDCR) selects LSB-first or MSB-first transfer. With an 8-bit data length, LSB-first/MSB-first selection is available regardless of the communication mode.

### 16.3.10 Bit Rate Register (SCBRR)

SCBRR is an 8-bit register that, together with the baud rate generator clock source selected by the CKS1 and CKS0 bits in the serial mode register (SCSMR), determines the serial transmit/receive bit rate.

The CPU can always read and write to SCBRR.

The SCBRR setting is calculated as follows:

Asynchronous mode:

- When the ABCS bit in serial extended mode register (SCSEMR) is 0

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

- When the ABCS bit in serial extended mode register (SCSEMR) is 1

$$N = \frac{P\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Clock synchronous mode:

$$N = \frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bits/s)

N: SCBRR setting for baud rate generator ( $0 \leq N \leq 255$ )  
(The setting value should satisfy the electrical characteristics.)

P $\phi$ : Operating frequency for peripheral modules (MHz)

n: Baud rate generator clock source ( $n = 0, 1, 2, 3$ ) (for the clock sources and values of n, see table 16.3.)

**Table 16.3 SCSMR Settings**

| n | Clock Source | SCSMR Settings |      |
|---|--------------|----------------|------|
|   |              | CKS1           | CKS0 |
| 0 | P $\phi$     | 0              | 0    |
| 1 | P $\phi$ /4  | 0              | 1    |
| 2 | P $\phi$ /16 | 1              | 0    |
| 3 | P $\phi$ /64 | 1              | 1    |

Note: The bit rate error in asynchronous is given by the following formula:

- When the ABCS bit in serial extended mode register (SCSEMR) is 0

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

- When the ABCS bit in serial extended mode register (SCSEMR) is 1

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$

Tables 16.4 to 16.6 show examples of SCBRR settings in asynchronous mode, and tables 16.7 to 16.9 show examples of SCBRR settings in clock synchronous mode.

**Table 16.4 Bit Rates and SCBRR Settings in Asynchronous Mode (1)**

| Bit<br>Rate<br>(bits/s) | P $\Phi$ (MHz) |     |           |    |     |           |    |     |           |    |     |           |    |     |           |    |     |           |

[Legend]

Blank: No setting possible

—: Setting possible, but error occurs

\*: Continuous transmission/reception is disabled.

Note: Settings with an error of 1% or less are recommended.

Table 16.10 indicates the maximum bit rates in asynchronous mode when the baud rate generator is used. Table 16.11 indicates the maximum bit rates in clock synchronous mode when the baud rate generator is used. Tables 16.12 and 16.13 list the maximum rates for external clock input.

**Table 16.10 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (Asynchronous Mode)**

| P $\phi$ (MHz) | At Non-Continuous<br>Transmission/Reception |          |   | At Continuous<br>Transmission/Reception |          |   |
|----------------|---------------------------------------------|----------|---|-----------------------------------------|----------|---|

## 16.4 Operation

### 16.4.1 Overview

For serial communication, the SCI has an asynchronous mode in which characters are synchronized individually, and a clock synchronous mode in which communication is synchronized with clock pulses.

Asynchronous or clock synchronous mode is selected and the transmit format is specified in the serial mode register (SCSMR) as shown in table 16.14. The SCI clock source is selected by the combination of the C/A bit in SCSMR and the CKE1 and CKE0 bits in the serial control register (SCSCR) as shown in table 16.15.

#### (1) Asynchronous Mode

- Data length is selectable: 7 or 8 bits.
- Parity bit is selectable. So is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors, parity errors, overrun errors, and breaks.
- An internal or external clock can be selected as the SCI clock source.
  - When an internal clock is selected, the SCI operates using the clock supplied by the on-chip baud rate generator and can output a clock with a frequency 16 times the bit rate.
  - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

#### (2) Clock Synchronous Mode

- The transmission/reception format has a fixed 8-bit data length.
- In receiving, it is possible to detect overrun errors.
- An internal or external clock can be selected as the SCI clock source.
  - When an internal clock is selected, the SCI operates using the on-chip baud rate generator, and outputs a serial clock signal to external devices.
  - When an external clock is selected, the SCI operates on the input serial clock. The on-chip baud rate generator is not used.

## 16.4.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCI are independent, so full duplex communication is possible. Both the transmitter and receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transfer.

Figure 16.2 shows the general format of asynchronous serial communication. In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCI monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCI synchronizes at the falling edge of the start bit. The SCI samples each data bit on the eighth pulse of a clock with a frequency 16 times the bit rate. Receive data is latched at the center of each bit.

**Figure 16.2 Example of Data Format in Asynchronous Communication  
(8-Bit Data with Parity and Two Stop Bits)**

## (1) Transmit/Receive Formats

Table 16.16 shows the transfer formats that can be selected in asynchronous mode. Any of 12 transfer formats can be selected according to the SCSMR settings.

**Table 16.16 Serial Transfer Formats (Asynchronous Mode)**

| SCSMR Settings |    |    |      | Serial Transfer Format and Frame Length |            |   |   |   |   |   |   |      |      |      |      |
|----------------|----|----|------|-----------------------------------------|------------|---|---|---|---|---|---|------|------|------|------|

| 1              | 1  | 0  | 0    | S                                       | 7-bit data |   |   |   |   |   |   | P    | STOP |      |      |
| 1              | 1  | 0  | 1    | S                                       | 7-bit data |   |   |   |   |   |   | P    | STOP | STOP |      |
| 0              | x  | 1  | 0    | S                                       | 8-bit data |   |   |   |   |   |   |      | MPB  | STOP |      |
| 0              | x  | 1  | 1    | S                                       | 8-bit data |   |   |   |   |   |   |      | MPB  | STOP | STOP |
| 1              | x  | 1  | 0    | S                                       | 7-bit data |   |   |   |   |   |   | MPB  | STOP |      |      |
| 1              | x  | 1  | 1    | S                                       | 7-bit data |   |   |   |   |   |   | MPB  | STOP | STOP |      |

[Legend]

S: Start bit

STOP: Stop bit

P: Parity bit

MPB: Multiprocessor bit

x: Don't care

## (2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCI transmit/receive clock. The clock source is selected by the  $C/\bar{A}$  bit in the serial mode register (SCSMR) and bits CKE1 and CKE0 in the serial control register (SCSCR) (table 16.15).

When an external clock is input at the SCK pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCI operates on an internal clock, it can output a clock signal at the SCK pin. The frequency of this output clock is equal to 16 times the desired bit rate.

## (3) Transmitting and Receiving Data

- SCI Initialization (Asynchronous Mode)

Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCI as follows.

When changing the operation mode or the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing the TE bit to 0 sets the TDRE flag to 1 and initializes the transmit shift register (SCTSR). Clearing the RE bit to 0, however, does not initialize the RDRF, PER, FER, and ORER flags or receive data register (SCRDR), which retain their previous contents.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCI operation becomes unreliable if the clock is stopped.

- [1] Set the clock selection in SCSCR.
- [2] Set the data transfer format in SCSMR and SCSDCR.
- [3] Write a value corresponding to the bit rate to SCBRR. Not necessary if an external clock is used.
- [4] Set PFC of the external pin used. Set RXD input during receiving and TXD output during transmitting. Set SCK input/output according to contents set by CKE1 and CKE0. When CKE1 and CKE0 are 0 in asynchronous mode, setting the SCK pin is unnecessary. Outputting clocks from the SCK pin starts at synchronous clock output setting.
- [5] Set the TE bit or RE bit in SCSCR to 1.\* Also make settings of the RIE, TIE, TEIE, and MPIE bits. At this time, the TXD, RXD, and SCK pins are ready to be used. The TXD pin is in a mark state during transmitting, and RXD pin is in an idle state for waiting the start bit during receiving.

Note : \* In simultaneous transmit/receive operation, the TE and RE bits must be cleared to 0 or set to 1 simultaneously.

**Figure 16.3 Sample Flowchart for SCI Initialization**

- Transmitting Serial Data (Asynchronous Mode)

Figure 16.4 shows a sample flowchart for serial transmission. Use the following procedure for serial data transmission after enabling the SCI for transmission.

**Figure 16.4 Sample Flowchart for Transmitting Serial Data**

In serial transmission, the SCI operates as described below.

1. The SCI monitors the TDRE flag in the serial status register (SCSSR). If it is cleared to 0, the SCI recognizes that data has been written to the transmit data register (SCTDR) and transfers the data from SCTDR to the transmit shift register (SCTSR).
2. After transferring data from SCTDR to SCTSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in the serial control register (SCSCR) is set to 1 at this time, a transmit-data-empty interrupt (TXI) request is generated.

The serial transmit data is sent from the TXD pin in the following order.

- A. Start bit: One-bit 0 is output.
  - B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - C. Parity bit or multiprocessor bit: One parity bit (even or odd parity) or one multiprocessor bit is output. (A format in which neither parity nor multiprocessor bit is output can also be selected.)
  - D. Stop bit(s): One or two 1 bits (stop bits) are output.
  - E. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCI checks the TDRE flag at the timing for sending the stop bit.  
If the TDRE flag is 0, the data is transferred from SCTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.  
If the TDRE flag is 1, the TEND flag in SCSSR is set to 1, the stop bit is sent, and then the "mark state" is entered in which 1 is output. If the TEIE bit in SCSCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 16.5 shows an example of the operation for transmission.

**Figure 16.5 Example of Transmission in Asynchronous Mode  
(8-Bit Data, Parity, One Stop Bit)**

- Receiving Serial Data (Asynchronous Mode)

Figure 16.6 shows a sample flowchart for serial reception. Use the following procedure for serial data reception after enabling the SCI for reception.

**Figure 16.6 Sample Flowchart for Receiving Serial Data (1)**

**Figure 16.6 Sample Flowchart for Receiving Serial Data (2)**

In serial reception, the SCI operates as described below.

1. The SCI monitors the transmission line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
2. The received data is stored in SCRSR in LSB-to-MSB order.
3. The parity bit and stop bit are received.

After receiving these bits, the SCI carries out the following checks.

- A. Parity check: The SCI counts the number of 1s in the received data and checks whether the count matches the even or odd parity specified by the O/E bit in the serial mode register (SCSMR).
- B. Stop bit check: The SCI checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
- C. Status check: The SCI checks whether the RDRF flag is 0 and the received data can be transferred from the receive shift register (SCRSR) to SCRDR.

If all the above checks are passed, the RDRF flag is set to 1 and the received data is stored in SCRDR. If a receive error is detected, the SCI operates as shown in table 16.17.

Note: When a receive error occurs, subsequent reception cannot be continued. In addition, the RDRF flag will not be set to 1 after reception; be sure to clear the error flag to 0.

4. If the EIO bit in SCSPTR is cleared to 0 and the RIE bit in SCSCR is set to 1 when the RDRF flag changes to 1, a receive-data-full interrupt (RXI) request is generated. If the RIE bit in SCSCR is set to 1 when the ORER, PER, or FER flag changes to 1, a receive error interrupt (ERI) request is generated.

**Table 16.17 Receive Errors and Error Conditions**

| Receive Error | Abbreviation | Error Condition                                                                    | Data Transfer                                             |
|---------------|--------------|------------------------------------------------------------------------------------|-----------------------------------------------------------|
| Overrun error | ORER         | When the next data reception is completed while the RDRF flag in SCSSR is set to 1 | The received data is not transferred from SCRSR to SCRDR. |
| Framing error | FER          | When the stop bit is 0                                                             | The received data is transferred from SCRSR to SCRDR.     |
| Parity error  | PER          | When the received data does not match the even or odd parity specified in SCSMR    | The received data is transferred from SCRSR to SCRDR.     |

Figure 16.7 shows an example of the operation for reception.

**Figure 16.7 Example of SCI Receive Operation  
(8-Bit Data, Parity, One Stop Bit)**

### 16.4.3 Clock Synchronous Mode

In clock synchronous mode, the SCIF transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCI transmitter and receiver are independent, so full-duplex communication is possible while sharing the same clock. Both the transmitter and receiver have a double-buffered structure so that data can be read or written during transmission or reception, enabling continuous data transfer.

Figure 16.8 shows the general format in clock synchronous serial communication.

**Figure 16.8 Data Format in Clock Synchronous Communication**

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data is guaranteed valid at the rising edge of the serial clock. In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB.

In clock synchronous mode, the SCI transmits or receives data by synchronizing with the rising edge of the serial clock.

### (1) Communication Format

The data length is fixed at eight bits. No parity bit can be added.

### (2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCI transmit/receive clock. For selection of the SCI clock source, see table 16.15.

When the SCI operates on an internal clock, it outputs the clock signal at the SCK pin. Eight clock pulses are output per transmitted or received character. When the SCI is not transmitting or receiving, the clock signal remains in the high state. However, in reception-only operation, the synchronizing clock is output until an overrun error occurs or the RE bit is cleared to 0. In operations for the reception of n characters, select the external clock as the clock source for the SCI. If the internal clock is to be used instead, set the RE and TE bits to 1, and then transmit n characters of dummy data during reception of the n characters to be received.

### (3) Transmitting and Receiving Data

- SCI Initialization (Clock Synchronous Mode)

Before transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCI. Clearing TE to 0 sets the TDRE flag to 1 and initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDRF, PER, FER, and ORER flags and receive data register (SCRDR), which retain their previous contents.

Figure 16.9 shows a sample flowchart for initializing the SCI.

**Figure 16.9 Sample Flowchart for SCI Initialization**

- Transmitting Serial Data (Clock Synchronous Mode)

Figure 16.10 shows a sample flowchart for transmitting serial data. Use the following procedure for serial data transmission after enabling the SCI for transmission.

**Figure 16.10 Sample Flowchart for Transmitting Serial Data**

In transmitting serial data, the SCI operates as follows:

1. The SCI monitors the TDRE flag in the serial status register (SCSSR). If it is cleared to 0, the SCI recognizes that data has been written to the transmit data register (SCTDR) and transfers the data from SCTDR to the transmit shift register (SCTSR).
2. After transferring data from SCTDR to SCTSR, the SCI sets the TDRE flag to 1 and starts transmission. If the transmit-data-empty interrupt enable bit (TIE) in the serial control register (SCSCR) is set to 1 at this time, a transmit-data-empty interrupt (TXI) request is generated. If clock output mode is selected, the SCI outputs eight synchronous clock pulses. If an external clock source is selected, the SCI outputs data in synchronization with the input clock. Data is output from the TXD pin in order from the LSB (bit 0) to the MSB (bit 7).
3. The SCI checks the TDRE flag at the timing for sending the MSB (bit 7). If the TDRE flag is 0, the data is transferred from SCTDR to SCTSR and serial transmission of the next frame is started. If the TDRE flag is 1, the TEND flag in SCSSR is set to 1, the MSB (bit 7) is sent, and then the TXD pin holds the states. If the TEIE bit in SCSCR is set to 1 at this time, a TEI interrupt request is generated.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 16.11 shows an example of SCI transmit operation.

**Figure 16.11 Example of SCI Transmit Operation**

- Receiving Serial Data (Clock Synchronous Mode)

Figure 16.12 shows a sample flowchart for receiving serial data. Use the following procedure for serial data reception after enabling the SCIF for reception.

When switching from asynchronous mode to clock synchronous mode, make sure that the ORER, PER, and FER flags are all cleared to 0. If the FER or PER flag is set to 1, the RDRF flag will not be set and data reception cannot be started.

**Figure 16.12 Sample Flowchart for Receiving Serial Data (1)**

**Figure 16.12 Sample Flowchart for Receiving Serial Data (2)**

In receiving, the SCI operates as follows:

1. The SCI synchronizes with serial clock input or output and initializes internally.
2. Receive data is shifted into SCRSR in order from the LSB to the MSB. After receiving the data, the SCI checks whether the RDRF flag is 0 and the receive data can be transferred from SCRSR to SCRDR. If this check is passed, the SCI sets the RDRF flag to 1 and stores the received data in SCRDR. If a receive error is detected, the SCI operates as shown in table 16.17. In this state, subsequent reception cannot be continued. In addition, the RDRF flag will not be set to 1 after reception; be sure to clear the RDRF flag to 0.
3. After setting RDRF to 1, if the receive-data-full interrupt enable bit (RIE) is set to 1 in SCSCR, the SCI requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the RIE bit in SCSCR is also set to 1, the SCI requests a receive error interrupt (ERI).

Figure 16.13 shows an example of SCI receive operation.

**Figure 16.13 Example of SCI Receive Operation**

- Transmitting and Receiving Serial Data Simultaneously (Clock Synchronous Mode)

Figure 16.14 shows a sample flowchart for transmitting and receiving serial data simultaneously. Use the following procedure for serial data transmission and reception after enabling the SCI for transmission and reception.

- [1] SCI status check and transmit data write:  
Read SCSSR and check that the TDRE flag is set to 1, then write transmit data to SCTDR and clear the TDRE flag to 0.  
Transition of the TDRE flag from 0 to 1 can also be identified by a TXI interrupt.
- [2] Receive error processing:  
If a receive error occurs, read the ORER flag in SCSSR, and after performing the appropriate error processing, clear the ORER flag to 0.  
Reception cannot be resumed if the ORER flag is set to 1.
- [3] SCI status check and receive data read:  
Read SCSSR and check that the RDRF flag is set to 1, then read the receive data in SCRDR and clear the RDRF flag to 0. Transition of the RDRF flag from 0 to 1 can also be identified by an RXI interrupt.
- [4] Serial transmission/reception continuation procedure:  
To continue serial transmission/reception, before the MSB (bit 7) of the current frame is received, finish reading the RDRF flag, reading SCRDR, and clearing the RDRF flag to 0. Also, before the MSB (bit 7) of the current frame is transmitted, read 1 from the TDRE flag to confirm that writing is possible. Then write data to SCTDR and clear the TDRE flag to 0. Checking and clearing of the TDRE flag is automatic when the DTC is activated by a transmit data empty interrupt (TXI) request and data is written to SCTDR. Also, the RDRF flag is cleared automatically when the DTC is activated by a receive data full interrupt (RXI) request and the SCRDR value is read.

Note: When switching from transmit or receive operation to simultaneous transmit and receive operations, first clear the TE bit and RE bit to 0, then set both these bits to 1 simultaneously.

**Figure 16.14 Sample Flowchart for Transmitting/Receiving Serial Data**

### 16.4.4 Multiprocessor Communication Function

Use of the multiprocessor communication function enables data transfer to be performed among a number of processors sharing communication lines by means of asynchronous serial communication using the multiprocessor format, in which a multiprocessor bit is added to the transfer data. When multiprocessor communication is carried out, each receiving station is addressed by a unique ID code. The serial communication cycle consists of two component cycles: an ID transmission cycle which specifies the receiving station, and a data transmission cycle. The multiprocessor bit is used to differentiate between the ID transmission cycle and the data transmission cycle. If the multiprocessor bit is 1, the cycle is an ID transmission cycle, and if the multiprocessor bit is 0, the cycle is a data transmission cycle. Figure 16.15 shows an example of inter-processor communication using the multiprocessor format. The transmitting station first sends the ID code of the receiving station with which it wants to perform serial communication as data with a 1 multiprocessor bit added. It then sends transmit data as data with a 0 multiprocessor bit added. The receiving station skips data until data with a 1 multiprocessor bit is sent. When data with a 1 multiprocessor bit is received, the receiving station compares that data with its own ID. The station whose ID matches then receives the data sent next. Stations whose ID does not match continue to skip data until data with a 1 multiprocessor bit is again received.

The SCI uses the MPIE bit in SCSCR to implement this function. When the MPIE bit is set to 1, transfer of receive data from SCRSR to SCRDR, error flag detection, and setting the SCSSR status flags, RDRF, FER, and OER to 1 are inhibited until data with a 1 multiprocessor bit is received. On reception of receive character with a 1 multiprocessor bit, the MPBR bit in SCSSR is set to 1 and the MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCSCR is set to 1 at this time, an RXI interrupt is generated.

When the multiprocessor format is selected, the parity bit setting is invalid. All other bit settings are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

**Figure 16.15 Example of Communication Using Multiprocessor Format  
(Transmission of Data H'AA to Receiving Station A)**

## 16.4.5 Multiprocessor Serial Data Transmission

Figure 16.16 shows a sample flowchart for multiprocessor serial data transmission. For an ID transmission cycle, set the MPBT bit in SCSSR to 1 before transmission. Keep MPBT at 1 until the ID is actually transmitted. For a data transmission cycle, clear the MPBT bit in SCSSR to 0 before transmission. All other SCI operations are the same as those in asynchronous mode.

**Figure 16.16 Sample Multiprocessor Serial Transmission Flowchart**

## 16.4.6 Multiprocessor Serial Data Reception

Figure 16.18 shows a sample flowchart for multiprocessor serial data reception. If the MPIE bit in SCSCR is set to 1, data is skipped until data with a 1 multiprocessor bit is sent. On receiving data with a 1 multiprocessor bit, the receive data is transferred to SCRDR. An RXI interrupt request is generated at this time. All other SCI operations are the same as in asynchronous mode. Figure 16.17 shows an example of SCI operation for multiprocessor format reception.

**Figure 16.17 Example of SCI Operation in Reception**  
(Example with 8-Bit Data, Multiprocessor Bit, One Stop Bit)

- [1] SCI initialization:  
Set the RXD pin using the PFC.
- [2] ID reception cycle:  
Set the MPIE bit in SCSSR to 1.
- [3] SCI status check, ID reception and comparison:  
Read SCSSR and check that the RDRF flag is set to 1, then read the receive data in SCRDR and compare it with this station's ID.  
If the data is not this station's ID, set the MPIE bit to 1 again, and clear the RDRF flag to 0.  
If the data is this station's ID, clear the RDRF flag to 0.
- [4] SCI status check and data reception:  
Read SCSSR and check that the RDRF flag is set to 1, then read the data in SCRDR.
- [5] Receive error processing and break detection:  
If a receive error occurs, read the ORER and FER flags in SCSSR to identify the error.  
After performing the appropriate error processing, ensure that the ORER and FER flags are all cleared to 0.  
Reception cannot be resumed if either of these flags is set to 1.  
In the case of a framing error, a break can be detected by reading the RXD pin value.

Figure 16.18 Sample Multiprocessor Serial Reception Flowchart (1)

**Figure 16.18 Sample Multiprocessor Serial Reception Flowchart (2)**

## 16.5 SCI Interrupt Sources and DTC

The SCI has four interrupt sources: transmit end (TEI), receive error (ERI), receive-data-full (RXI), and transmit-data-empty (TXI) interrupt requests.

Table 16.18 shows the interrupt sources. The interrupt sources are enabled or disabled by means of the TIE, RIE, and TEIE bits in SCSCR and the EIO bit in SCSPTR. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When the TDRE flag in the serial status register (SCSSR) is set to 1, a TDR empty interrupt request is generated. This request can be used to activate the data transfer controller (DTC) to transfer data. The TDRE flag is automatically cleared to 0 when data is written to the transmit data register (SCTDR) through the DTC.

When the RDRF flag in SCSSR is set to 1, an RDR full interrupt request is generated. This request can be used to activate the DTC to transfer data. The RDRF flag is automatically cleared to 0 when data is read from the receive data register (SCRDR) through the DTC.

When the ORER, FER, or PER flag in SCSSR is set to 1, an ERI interrupt request is generated. This request cannot be used to activate the DTC. In processing for data reception, generation of ERI interrupt requests can only be enabled if generation of RXI interrupt requests is disabled. In this case, set the RIE bit and the EIO bit in SCSPTR to 1. However, note that the DMAC or DTC will not transfer received data since RXI interrupt requests are not generated while the EIO bit is set to 1.

When the TEND flag in SCSSR is set to 1, a TEI interrupt request is generated. This request cannot be used to activate the DTC.

The TXI interrupt indicates that transmit data can be written, and the TEI interrupt indicates that transmission has been completed.

**Table 16.18 SCI Interrupt Sources**

| Interrupt Source | Description                                           | DTC Activation |
|------------------|-------------------------------------------------------|----------------|
| ERI              | Interrupt caused by receive error (ORER, FER, or PER) | Not possible   |
| RXI              | Interrupt caused by receive data full (RDRF)          | Possible       |
| TXI              | Interrupt caused by transmit data empty (TDRE)        | Possible       |
| TEI              | Interrupt caused by transmit end (TENT)               | Not possible   |

## 16.6 Serial Port Register (SCSPTR) and SCI Pins

The relationship between SCSPTR and the SCI pins is shown in figures 16.19 and 16.20.

**Figure 16.19 SCKIO Bit, SCKDT Bit, and SCK Pin**

**Figure 16.20 SPBDT Bit and TXD Pin**

## 16.7 Usage Notes

### 16.7.1 SCTDR Writing and TDRE Flag

The TDRE flag in the serial status register (SCSSR) is a status flag indicating transferring of transmit data from SCTDR into SCTSR. The SCI sets the TDRE flag to 1 when it transfers data from SCTDR to SCTSR.

Data can be written to SCTDR regardless of the TDRE bit status.

If new data is written in SCTDR when TDRE is 0, however, the old data stored in SCTDR will be lost because the data has not yet been transferred to SCTSR. Before writing transmit data to SCTDR, be sure to check that the TDRE flag is set to 1.

### 16.7.2 Multiple Receive Error Occurrence

If multiple receive errors occur at the same time, the status flags in SCSSR are set as shown in table 16.19. When an overrun error occurs, data is not transferred from the receive shift register (SCRSR) to the receive data register (SCRDR) and the received data will be lost.

**Table 16.19 SCSSR Status Flag Values and Transfer of Received Data**

| Receive Errors Generated                     | SCSSR Status Flags |      |     |     | Receive Data Transfer from SCRSR to SCRDR |
|----------------------------------------------|--------------------|------|-----|-----|-------------------------------------------|
|                                              | RDRF               | ORER | FER | PER |                                           |
| Overrun error                                | 1                  | 1    | 0   | 0   | Not transferred                           |
| Framing error                                | 0                  | 0    | 1   | 0   | Transferred                               |
| Parity error                                 | 0                  | 0    | 0   | 1   | Transferred                               |
| Overrun error + framing error                | 1                  | 1    | 1   | 0   | Not transferred                           |
| Overrun error + parity error                 | 1                  | 1    | 0   | 1   | Not transferred                           |
| Framing error + parity error                 | 0                  | 0    | 1   | 1   | Transferred                               |
| Overrun error + framing error + parity error | 1                  | 1    | 1   | 1   | Not transferred                           |

### 16.7.3 Break Detection and Processing

Break signals can be detected by reading the RXD pin directly when a framing error (FER) is detected. In the break state the input from the RXD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set. Note that, although transfer of receive data to SCRDR is halted in the break state, the SCI receiver continues to operate.

### 16.7.4 Sending a Break Signal

The I/O condition and level of the TXD pin are determined by SPB0DT bit in the serial port register (SCSPTR). This feature can be used to send a break signal.

Until TE bit is set to 1 (enabling transmission) after initializing, TXD pin does not work. During the period, mark status is performed by SPB0DT bit. Therefore, the SPB0DT bit should be set to 1 (high level output).

To send a break signal during serial transmission, clear the SPB0DT bit to 0 (low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TXD pin.

### 16.7.5 Receive Data Sampling Timing and Receive Margin (Asynchronous Mode)

The SCI operates on a base clock with a frequency of 16 times the transfer rate in asynchronous mode. In reception, the SCI synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse. The timing is shown in figure 16.21.

**Figure 16.21 Receive Data Sampling Timing in Asynchronous Mode**

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

**Equation 1:**

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1+F) \right| \times 100 \%$$

Where: M: Receive margin (%)

N: Ratio of bit rate to clock (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

**Equation 2:**

When D = 0.5 and F = 0:

$$\begin{aligned} M &= (0.5 - 1/(2 \times 16)) \times 100\% \\ &= 46.875\% \end{aligned}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

### 16.7.6 Note on Using DTC

When the external clock source is used for the clock for synchronization, input the external clock after waiting for five or more cycles of the peripheral operating clock after SCTDR is modified through the DTC. If a transmit clock is input within four cycles after SCTDR is modified, a malfunction may occur (figure 16.22).

**Figure 16.22 Example of Clock Synchronous Transfer Using DTC**

When data is written to SCTDR by activating the DTC by a TXI interrupt, the TEND flag value becomes undefined. In this case, do not use the TEND flag as the transmit end flag.

### 16.7.7 Note on Using External Clock in Clock Synchronous Mode

TE and RE must be set to 1 after waiting for four or more cycles of the peripheral operating clock after the SCK external clock is changed from 0 to 1.

TE and RE must be set to 1 only while the SCK external clock is 1.

### 16.7.8 Module Standby Mode Setting

SCI operation can be disabled or enabled using the standby control register. The initial setting is for SCI operation to be halted. Register access is enabled by clearing module standby mode. For details, refer to section 30, Power-Down Modes.

## Section 17 Serial Communication Interface with FIFO (SCIF)

This LSI has one channel of serial communication interface with FIFO (SCIF) that supports both asynchronous and clocked synchronous serial communication. It also has 16-stage FIFO registers for both transmission and reception independently for each channel that enable this LSI to perform efficient high-speed continuous communication.

### 17.1 Features

- Asynchronous serial communication:
  - Serial data communication is performed by start-stop in character units. The SCIF can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communications interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are eight selectable serial data communication formats.
  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even, odd, or none
  - Receive error detection: Parity, framing, and overrun errors
  - Break detection: Break is detected when a framing error is followed by at least one frame at the space 0 level (low level). It is also detected by reading the RXD level directly from the serial port register when a framing error occurs.
- Clocked synchronous serial communication:
  - Serial data communication is synchronized with a clock signal. The SCIF can communicate with other chips having a clocked synchronous communication function. There is one serial data communication format.
  - Data length: 8 bits
  - Receive error detection: Overrun errors
- Full duplex communication: The transmitting and receiving sections are independent, so the SCIF can transmit and receive simultaneously. Both sections use 16-stage FIFO buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal) or SCK pin (external)

- Four types of interrupts: Transmit-FIFO-data-empty interrupt, break interrupt, receive-FIFO-data-full interrupt, and receive-error interrupts are requested independently.
- When the SCIF is not in use, it can be stopped by halting the clock supplied to it, saving power.
- The quantity of data in the transmit and receive FIFO data registers and the number of receive errors of the receive data in the receive FIFO data register can be ascertained.
- A time-out error (DR) can be detected when receiving in asynchronous mode.

Figure 17.1 shows a block diagram of the SCIF.

**Figure 17.1 Block Diagram of SCIF**

## 17.2 Input/Output Pins

Table 17.1 shows the pin configuration of the SCIF.

**Table 17.1 Pin Configuration**

| Channel | Pin Name           | Symbol | I/O    | Function             |
|---------|--------------------|--------|--------|----------------------|
| 3       | Serial clock pins  | SCK3   | I/O    | Clock I/O            |
|         | Receive data pins  | RXD3   | Input  | Receive data input   |
|         | Transmit data pins | TXD3   | Output | Transmit data output |

## 17.3 Register Descriptions

The SCIF has the following registers.

**Table 17.2 Register Configuration**

| Channel | Register Name                   | Abbreviation | R/W                 | Initial Value | Address    | Access Size |
|---------|---------------------------------|--------------|---------------------|---------------|------------|-------------|
| 3       | Serial mode register_3          | SCSMR_3      | R/W                 | H'0000        | H'FFFE9800 | 16          |
|         | Bit rate register_3             | SCBRR_3      | R/W                 | H'FF          | H'FFFE9804 | 8           |
|         | Serial control register_3       | SCSCR_3      | R/W                 | H'0000        | H'FFFE9808 | 16          |
|         | Transmit FIFO data register_3   | SCFTDR_3     | W                   | Undefined     | H'FFFE980C | 8           |
|         | Serial status register_3        | SCFSR_3      | R/(W)* <sup>1</sup> | H'0060        | H'FFFE9810 | 16          |
|         | Receive FIFO data register_3    | SCFRDR_3     | R                   | Undefined     | H'FFFE9814 | 8           |
|         | FIFO control register_3         | SCFCR_3      | R/W                 | H'0000        | H'FFFE9818 | 16          |
|         | FIFO data count register_3      | SCFDR_3      | R                   | H'0000        | H'FFFE981C | 16          |
|         | Serial port register_3          | SCSPTR_3     | R/W                 | H'005x        | H'FFFE9820 | 16          |
|         | Line status register_3          | SCLSR_3      | R/(W)* <sup>2</sup> | H'0000        | H'FFFE9824 | 16          |
|         | Serial extended mode register_3 | SCSEMR_3     | R/W                 | H'00          | H'FFFE9900 | 8           |

- Notes: 1. Only 0 can be written to clear the flag. Bits 15 to 8, 3, and 2 are read-only bits that cannot be modified.
2. Only 0 can be written to clear the flag. Bits 15 to 1 are read-only bits that cannot be modified.

### 17.3.1 Receive Shift Register (SCRSR)

SCRSR receives serial data. Data input at the RXD pin is loaded into SCRSR in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to the receive FIFO data register (SCFRDR).

The CPU cannot read or write to SCRSR directly.

|                |   |   |   |   |   |   |   |   |
|----------------|---|---|---|---|---|---|---|---|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |   |   |   |   |   |   |   |   |
| Initial value: | - | - | - | - | - | - | - | - |
| R/W:           | - | - | - | - | - | - | - | - |

### 17.3.2 Receive FIFO Data Register (SCFRDR)

SCFRDR is a register that stores serial receive data. The SCIF completes the reception of one byte of serial data by moving the received data from the receive shift register (SCRSR) into SCFRDR for storage. Continuous reception is possible until 16 bytes are stored. The CPU can read but not write to SCFRDR. If data is read when there is no receive data in the SCFRDR, the value is undefined.

When SCFRDR is full of receive data, subsequent serial data is lost.

SCFRDR is initialized to an undefined value by a power-on reset.

|                |   |   |   |   |   |   |   |   |
|----------------|---|---|---|---|---|---|---|---|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |   |   |   |   |   |   |   |   |
| Initial value: | - | - | - | - | - | - | - | - |
| R/W:           | R | R | R | R | R | R | R | R |

### 17.3.3 Transmit Shift Register (SCTSR)

SCTSR transmits serial data. The SCIF loads transmit data from the transmit FIFO data register (SCFTDR) into SCTSR, then transmits the data serially from the TXD pin, LSB (bit 0) first. After transmitting one data byte, the SCIF automatically loads the next transmit data from SCFTDR into SCTSR and starts transmitting again.

The CPU cannot read or write to SCTSR directly.

|                |             |             |             |             |             |             |             |             |
|----------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Bit:           | 7           | 6           | 5           | 4           | 3           | 2           | 1           | 0           |
|                | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> |
| Initial value: | -           | -           | -           | -           | -           | -           | -           | -           |
| R/W:           | -           | -           | -           | -           | -           | -           | -           | -           |

### 17.3.4 Transmit FIFO Data Register (SCFTDR)

SCFTDR is a 16-byte FIFO register that stores data for serial transmission. When the SCIF detects that the transmit shift register (SCTSR) is empty, it moves transmit data written in the SCFTDR into SCTSR and starts serial transmission. Continuous serial transmission is performed until there is no transmit data left in SCFTDR. The CPU can write to SCFTDR at all times.

When SCFTDR is full of transmit data (16 bytes), no more data can be written. If writing of new data is attempted, the data is ignored.

SCFTDR is initialized to an undefined value by a power-on reset.

|                |             |             |             |             |             |             |             |             |
|----------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| Bit:           | 7           | 6           | 5           | 4           | 3           | 2           | 1           | 0           |
|                | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> | <div></div> |
| Initial value: | -           | -           | -           | -           | -           | -           | -           | -           |
| R/W:           | W           | W           | W           | W           | W           | W           | W           | W           |

### 17.3.5 Serial Mode Register (SCSMR)

SCSMR specifies the SCIF serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to SCSMR. SCSMR is initialized to H'0000 by a power-on reset.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7   | 6   | 5   | 4   | 3    | 2 | 1        | 0   |

### 17.3.6 Serial Control Register (SCSCR)

SCSCR operates the SCIF transmitter/receiver, enables/disables interrupt requests, and selects the transmit/receive clock source. The CPU can always read and write to SCSCR. SCSCR is initialized to H'0000 by a power-on reset.

### 17.3.7 Serial Status Register (SCFSR)

SCFSR is a 16-bit register. The upper 8 bits indicate the number of receive errors in the receive FIFO data register, and the lower 8 bits indicate the status flag indicating SCIF operating state.

The CPU can always read and write to SCFSR, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, RDF, and DR). These flags can be cleared to 0 only if they have first been read (after being set to 1). Bits 3 (FER) and 2 (PER) are read-only bits that cannot be written.

When receive data in the receive FIFO data register is transferred by using the DTC/DMAC, the receive data is cleared in the receive FIFO data register. At the same time, the PER and FER bits in SCFSR are cleared. If the DTC/DMAC is used, an error is not judged by the FER or PER bit.

If an attempt is made to read after all the data in SCFRDR has been read, the data is undefined. The quantity of receive data in SCFRDR is indicated by the lower 8 bits of SCFDR.</p> |

| Bit | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----|----------|---------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DR       | 0             | R/(W)* | <p>Receive Data Ready</p> <p>Indicates that the quantity of data in the receive FIFO data register (SCFRDR) is less than the specified receive trigger number, and that the next data has not yet been received after the elapse of 15 ETU from the last stop bit in asynchronous mode. In clocked synchronous mode, this bit is not set to 1.</p> <p>0: Receiving is in progress, or no receive data remains in SCFRDR after receiving ended normally</p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>DR is cleared to 0 when the chip undergoes a power-on reset</li> <li>DR is cleared to 0 when all receive data are read after 1 is read from DR and then 0 is written.</li> <li>DR is cleared to 0 when all receive data in SCFRDR are read by the DMAC/DTC.</li> </ul> <p>1: Next receive data has not been received</p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>DR is set to 1 when SCFRDR contains less data than the specified receive trigger number, and the next data has not yet been received after the elapse of 15 ETU from the last stop bit.*</li> </ul> <p>Note: * This is equivalent to 1.5 frames with the 8-bit, 1-stop-bit format. (ETU: elementary time unit)</p> |

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 17.3.8 Bit Rate Register (SCBRR)

SCBRR is an 8-bit register that, together with the baud rate generator clock source selected by the CKS[1:0] bits in the serial mode register (SCSMR), determines the serial transmit/receive bit rate.

The CPU can always read and write to SCBRR. SCBRR is initialized to H'FF by a power-on reset.

The SCBRR setting is calculated as follows:

Asynchronous mode:

- When the ABCS bit in serial extended mode register (SCSEMR) is 0

$$N = \frac{P\phi}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

- When the ABCS bit in serial extended mode register (SCSEMR) is 1

$$N = \frac{P\phi}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

Clocked synchronous mode:

$$N = \frac{P\phi}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bits/s)

N: SCBRR setting for baud rate generator ( $0 \leq N \leq 255$ )  
(The setting must satisfy the electrical characteristics.)

Pφ: Operating frequency for peripheral modules (MHz)

n: Baud rate generator clock source (n = 0, 1, 2, 3) (for the clock sources and values of n, see table 17.3.)

**Table 17.3 SCSMR Settings**

| <b>n</b> | <b>Clock Source</b> | <b>SCSMR Settings</b> |             |
|----------|---------------------|-----------------------|-------------|
|          |                     | <b>CKS1</b>           | <b>CKS0</b> |
| 0        | P $\phi$            | 0                     | 0           |
| 1        | P $\phi$ /4         | 0                     | 1           |
| 2        | P $\phi$ /16        | 1                     | 0           |
| 3        | P $\phi$ /64        | 1                     | 1           |

The bit rate error in asynchronous is given by the following formula:

- When the ABCS bit in serial extended mode register (SCSEMR) is 0

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

- When the ABCS bit in serial extended mode register (SCSEMR) is 1

$$\text{Error (\%)} = \left\{ \frac{P\phi \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$

Table 17.4 lists examples of SCBRR settings in asynchronous mode, and table 17.5 lists examples of SCBRR settings in clocked synchronous mode.

**Table 17.4 Bit Rates and SCBRR Settings (Asynchronous Mode) (1)**

| Bit Rate<br>(Bit/s) | P <sub>φ</sub> (MHz) |     |           |     |     |           |     |     |           |     |     |           |     |     |           |    |    |           |

Notes: Settings with an error of 1% or less are recommended.

1. Cannot be set in this LSI.
2. Continuous transmission/reception is disabled.

[Legend]

Blank: Cannot be set.

—: Can be set with an error.

Table 17.10 indicates the maximum bit rates for various frequencies in asynchronous mode when the baud rate generator is used. Table 17.11 indicates the maximum bit rates for various frequencies when the baud rate generator is used. Tables 17.12 and 17.13 list the maximum bit rates when the external clock input is used.

**Table 17.10 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (Asynchronous Mode)**

### 17.3.9 FIFO Control Register (SCFCR)

SCFCR resets the quantity of data in the transmit and receive FIFO data registers, sets the trigger data quantity, and contains an enable bit for loop-back testing. SCFCR can always be read and written to by the CPU. It is initialized to H'0000 by a power-on reset.

### 17.3.10 FIFO Data Count Register (SCFDR)

SCFDR is a 16-bit register which indicates the quantity of data stored in the transmit FIFO data register (SCFTDR) and the receive FIFO data register (SCFRDR).

It indicates the quantity of transmit data in SCFTDR with the upper 8 bits, and the quantity of receive data in SCFRDR with the lower 8 bits. SCFDR can always be read by the CPU. SCFDR is initialized to H'0000 by a power on reset.

| 12 to 8  | T[4:0]   | 00000         | R   | T4 to T0 bits indicate the quantity of non-transmitted data stored in SCFTDR. H'00 means no transmit data, and H'10 means that SCFTDR is full of transmit data. |
| 7 to 5   | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                |
| 4 to 0   | R[4:0]   | 00000         | R   | R4 to R0 bits indicate the quantity of receive data stored in SCFRDR. H'00 means no receive data, and H'10 means that SCFRDR full of receive data.              |

### 17.3.11 Serial Port Register (SCSPTR)

SCSPTR controls input/output and data of pins multiplexed to SCIF function. Bits 3 and 2 can control input/output data of SCK pin. Bits 1 and 0 can input data from RXD pin and output data to TXD pin, so they control break of serial transmitting/receiving.

The CPU can always read and write to SCSPTR. SCSPTR is initialized to H'0050 by a power-on reset.

### 17.3.12 Line Status Register (SCLSR)

The CPU can always read or write to SCLSR, but cannot write 1 to the ORER flag. This flag can be cleared to 0 only if it has first been read (after being set to 1).

SCLSR is initialized to H'0000 by a power-on reset.

| 0       | ORER     | 0             | R/(W)* | <p>Overrun Error</p> <p>Indicates the occurrence of an overrun error.</p> <p>0: Receiving is in progress or has ended normally*<sup>1</sup></p> <p>[Clearing conditions]</p> <ul style="list-style-type: none"> <li>• ORER is cleared to 0 when the chip is a power-on reset</li> <li>• ORER is cleared to 0 when 0 is written after 1 is read from ORER.</li> </ul> <p>1: An overrun error has occurred*<sup>2</sup></p> <p>[Setting condition]</p> <ul style="list-style-type: none"> <li>• ORER is set to 1 when the next serial receiving is finished while the receive FIFO is full of 16-byte receive data.</li> </ul> <p>Notes: 1. Clearing the RE bit to 0 in SCSCR does not affect the ORER bit, which retains its previous value.</p> <p>2. The receive FIFO data register (SCFRDR) retains the data before an overrun error has occurred, and the next received data is discarded. When the ORER bit is set to 1, the SCIF cannot continue the next serial reception.</p> |

### 17.3.13 Serial Extended Mode Register (SCSEMR)

SCSEMR is an 8-bit register that extends the SCIF functions. The transfer rate can be doubled by setting the basic clock in asynchronous mode.

Be sure to set this register to H'00 in clocked synchronous mode. SCSEMR is initialized to H'00 by a power-on reset.

## 17.4 Operation

### 17.4.1 Overview

For serial communication, the SCIF has an asynchronous mode in which characters are synchronized individually, and a clocked synchronous mode in which communication is synchronized with clock pulses.

The SCIF has a 16-stage FIFO buffer for both transmission and receptions, reducing the overhead of the CPU, and enabling continuous high-speed communication.

The transmission format is selected in the serial mode register (SCSMR), as shown in table 17.14. The SCIF clock source is selected by the combination of the CKE1 and CKE0 bits in the serial control register (SCSCR), as shown in table 17.15.

#### (1) Asynchronous Mode

- Data length is selectable: 7 or 8 bits
- Parity bit is selectable. So is the stop bit length (1 or 2 bits). The combination of the preceding selections constitutes the communication format and character length.
- In receiving, it is possible to detect framing errors, parity errors, receive FIFO data full, overrun errors, receive data ready, and breaks.
- The number of stored data bytes is indicated for both the transmit and receive FIFO registers.
- An internal or external clock can be selected as the SCIF clock source.
  - When an internal clock is selected, the SCIF operates using the clock of on-chip baud rate generator.
  - When an external clock is selected, the external clock input must have a frequency 16 times the bit rate. (The on-chip baud rate generator is not used.)

#### (2) Clocked Synchronous Mode

- The transmission/reception format has a fixed 8-bit data length.
- In receiving, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the SCIF clock source.
  - When an internal clock is selected, the SCIF operates using the clock of the on-chip baud rate generator, and outputs this clock to external devices as the synchronous clock.
  - When an external clock is selected, the SCIF operates on the input synchronous clock not using the on-chip baud rate generator.

## 17.4.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCIF are independent, so full duplex communication is possible. The transmitter and receiver are 16-byte FIFO buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmitting and receiving.

Figure 17.2 shows the general format of asynchronous serial communication.

In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCIF monitors the line and starts serial communication when the line goes to the space (low) state, indicating a start bit. One serial character consists of a start bit (low), data (LSB first), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCIF synchronizes at the falling edge of the start bit. The SCIF samples each data bit on the eighth pulse of a clock with a frequency 16 times the bit rate. Receive data is latched at the center of each bit.

**Figure 17.2 Example of Data Format in Asynchronous Communication  
(8-Bit Data with Parity and Two Stop Bits)**

## (1) Transmit/Receive Formats

Table 17.16 lists the eight communication formats that can be selected in asynchronous mode. The format is selected by settings in the serial mode register (SCSMR).

**Table 17.16 Serial Communication Formats (Asynchronous Mode)**

| SCSMR Bits |    |      | Serial Transmit/Receive Format and Frame Length |            |   |   |   |   |   |      |      |      |      |    |
|------------|----|------|-------------------------------------------------|------------|---|---|---|---|---|------|------|------|------|----|
| CHR        | PE | STOP | 1                                               | 2          | 3 | 4 | 5 | 6 | 7 | 8    | 9    | 10   | 11   | 12 |
| 0          | 0  | 0    | START                                           | 8-bit data |   |   |   |   |   |      | STOP |      |      |    |
| 0          | 0  | 1    | START                                           | 8-bit data |   |   |   |   |   |      | STOP | STOP |      |    |
| 0          | 1  | 0    | START                                           | 8-bit data |   |   |   |   |   |      | P    | STOP |      |    |
| 0          | 1  | 1    | START                                           | 8-bit data |   |   |   |   |   |      | P    | STOP | STOP |    |
| 1          | 0  | 0    | START                                           | 7-bit data |   |   |   |   |   | STOP |      |      |      |    |
| 1          | 0  | 1    | START                                           | 7-bit data |   |   |   |   |   | STOP | STOP |      |      |    |
| 1          | 1  | 0    | START                                           | 7-bit data |   |   |   |   |   | P    | STOP |      |      |    |
| 1          | 1  | 1    | START                                           | 7-bit data |   |   |   |   |   | P    | STOP | STOP |      |    |

[Legend]

START: Start bit

STOP: Stop bit

P: Parity bit

## (2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCIF transmit/receive clock. The clock source is selected by the C/A bit in the serial mode register (SCSMR) and bits CKE[1:0] in the serial control register (SCSCR). For clock source selection, refer to table 17.15.

When an external clock is input at the SCK pin, it must have a frequency equal to 16 times the desired bit rate.

When the SCIF operates on an internal clock, it can output a clock signal on the SCK pin. The frequency of this output clock is 16 times the desired bit rate.

### (3) Transmitting and Receiving Data

#### • SCIF Initialization (Asynchronous Mode)

Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCIF as follows.

When changing the operating mode or the communication format, always clear the TE and RE bits to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing TE and RE to 0, however, does not initialize the serial status register (SCFSR), transmit FIFO data register (SCFTDR), or receive FIFO data register (SCFRDR), which retain their previous contents. Clear TE to 0 after all transmit data has been transmitted and the TEND flag in the SCFSR is set. The TE bit can be cleared to 0 during transmission, but the transmit data goes to the Mark state after the bit is cleared to 0. Set the TFRST bit in SCFCR to 1 and reset SCFTDR before TE is set again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIF operation becomes unreliable if the clock is stopped.

Figure 17.3 shows a sample flowchart for initializing the SCIF.

**Figure 17.3 Sample Flowchart for SCIF Initialization**

- Transmitting Serial Data (Asynchronous Mode)

Figure 17.4 shows a sample flowchart for serial transmission. Use the following procedure for serial data transmission after enabling the SCIF for transmission.

**Figure 17.4 Sample Flowchart for Transmitting Serial Data**

In serial transmission, the SCIF operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the SCIF transfers the data from SCFTDR to the transmit shift register (SCTSR) and starts transmitting. Confirm that the TDFFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 – transmit trigger setting).
2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

The serial transmit data is sent from the TXD pin in the following order.

- A. Start bit: One-bit 0 is output.
  - B. Transmit data: 8-bit or 7-bit data is output in LSB-first order.
  - C. Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
  - D. Stop bit(s): One or two 1 bits (stop bits) are output.
  - E. Mark state: 1 is output continuously until the start bit that starts the next transmission is sent.
3. The SCIF checks the SCFTDR transmit data at the timing for sending the stop bit. If data is present, the data is transferred from SCFTDR to SCTSR, the stop bit is sent, and then serial transmission of the next frame is started.

Figure 17.5 shows an example of the operation for transmission.

**Figure 17.5 Example of Transmit Operation  
(8-Bit Data, Parity, 1 Stop Bit)**

- Receiving Serial Data (Asynchronous Mode)

Figures 17.6 and 17.7 show sample flowcharts for serial reception. Use the following procedure for serial data reception after enabling the SCIF for reception.

**Figure 17.6 Sample Flowchart for Receiving Serial Data**

- Whether a framing error or parity error has occurred in the receive data that is to be read from the receive FIFO data register (SCFRDR) can be ascertained from the FER and PER bits in the serial status register (SCFSR).
- When a break signal is received, receive data is not transferred to SCFRDR while the BRK flag is set. However, note that the last data in SCFRDR is H'00, and the break data in which a framing error occurred is stored.

**Figure 17.7 Sample Flowchart for Receiving Serial Data (cont)**

In serial reception, the SCIF operates as described below.

1. The SCIF monitors the transmission line, and if a 0 start bit is detected, performs internal synchronization and starts reception.
2. The received data is stored in SCRSR in LSB-to-MSB order.
3. The parity bit and stop bit are received.

After receiving these bits, the SCIF carries out the following checks.

- A. Stop bit check: The SCIF checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
- B. The SCIF checks whether receive data can be transferred from the receive shift register (SCRSR) to SCFRDR.
- C. Overrun check: The SCIF checks that the ORER flag is 0, indicating that the overrun error has not occurred.
- D. Break check: The SCIF checks that the BRK flag is 0, indicating that the break state is not set.

If all the above checks are passed, the receive data is stored in SCFRDR.

Note: When a parity error or a framing error occurs, reception is not suspended.

4. If the RIE bit in SCSCR is set to 1 when the RDF or DR flag changes to 1, a receive-FIFO-data-full interrupt (RXI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the ER flag changes to 1, a receive-error interrupt (ERI) request is generated. If the RIE bit or the REIE bit in SCSCR is set to 1 when the BRK or ORER flag changes to 1, a break reception interrupt (BRI) request is generated.

Figure 17.8 shows an example of the operation for reception.

**Figure 17.8 Example of SCIF Receive Operation  
(8-Bit Data, Parity, 1 Stop Bit)**

### 17.4.3 Operation in Clocked Synchronous Mode

In clocked synchronous mode, the SCIF transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.

The SCIF transmitter and receiver are independent, so full-duplex communication is possible while sharing the same clock. The transmitter and receiver are also 16-byte FIFO buffered, so continuous transmitting or receiving is possible by reading or writing data while transmitting or receiving is in progress.

Figure 17.9 shows the general format in clocked synchronous serial communication.

**Figure 17.9 Data Format in Clocked Synchronous Communication**

In clocked synchronous serial communication, each data bit is output on the communication line from one falling edge of the serial clock to the next. Data is guaranteed valid at the rising edge of the serial clock.

In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB.

In clocked synchronous mode, the SCIF receives data by synchronizing with the rising edge of the serial clock.

### (1) Transmit/Receive Formats

The data length is fixed at eight bits. No parity bit can be added.

### (2) Clock

An internal clock generated by the on-chip baud rate generator by the setting of the C/A bit in SCSMR and CKE[1:0] in SCSCR, or an external clock input from the SCK pin can be selected as the SCIF transmit/receive clock.

When the SCIF operates on an internal clock, it outputs the clock signal at the SCK pin. Eight clock pulses are output per transmitted or received character. When the SCIF is not transmitting or receiving, the clock signal remains in the high state. When only receiving, the clock signal outputs while the RE bit of SCSCR is 1 and the number of data in receive FIFO is more than the receive FIFO data trigger number.

### (3) Transmitting and Receiving Data

- SCIF Initialization (Clocked Synchronous Mode)

Before transmitting, receiving, or changing the mode or communication format, the software must clear the TE and RE bits to 0 in the serial control register (SCSCR), then initialize the SCIF. Clearing TE to 0 initializes the transmit shift register (SCTSR). Clearing RE to 0, however, does not initialize the RDF, PER, FER, and ORER flags and receive data register (SCRDR), which retain their previous contents.

Figure 17.10 shows a sample flowchart for initializing the SCIF.

**Figure 17.10 Sample Flowchart for SCIF Initialization**

- Transmitting Serial Data (Clocked Synchronous Mode)

Figure 17.11 shows a sample flowchart for transmitting serial data. Use the following procedure for serial data transmission after enabling the SCIF for transmission.

**Figure 17.11 Sample Flowchart for Transmitting Serial Data**

In serial transmission, the SCIF operates as described below.

1. When data is written into the transmit FIFO data register (SCFTDR), the SCIF transfers the data from SCFTDR to the transmit shift register (SCTSR) and starts transmitting. Confirm that the TDFE flag in the serial status register (SCFSR) is set to 1 before writing transmit data to SCFTDR. The number of data bytes that can be written is (16 – transmit trigger setting).
2. When data is transferred from SCFTDR to SCTSR and transmission is started, consecutive transmit operations are performed until there is no transmit data left in SCFTDR. When the number of transmit data bytes in SCFTDR falls below the transmit trigger number set in the FIFO control register (SCFCR), the TDFE flag is set. If the TIE bit in the serial control register (SCSR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXI) request is generated.

If clock output mode is selected, the SCIF outputs eight synchronous clock pulses. If an external clock source is selected, the SCIF outputs data in synchronization with the input clock. Data is output from the TXD pin in order from the LSB (bit 0) to the MSB (bit 7).

3. The SCIF checks the SCFTDR transmit data at the timing for sending the MSB (bit 7). If data is present, the data is transferred from SCFTDR to SCTSR, and then serial transmission of the next frame is started. If there is no data, the TXD pin holds the state after the TEND flag in SCFSR is set to 1 and the MSB (bit 7) is sent.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 17.12 shows an example of SCIF transmit operation.

**Figure 17.12 Example of SCIF Transmit Operation**

### • Receiving Serial Data (Clocked Synchronous Mode)

Figures 17.13 and 17.14 show sample flowcharts for receiving serial data. When switching from asynchronous mode to clocked synchronous mode without SCIF initialization, make sure that ORER, PER, and FER are cleared to 0.

**Figure 17.13 Sample Flowchart for Receiving Serial Data (1)**

**Figure 17.14 Sample Flowchart for Receiving Serial Data (2)**

In serial reception, the SCIF operates as described below.

1. The SCIF synchronizes with serial clock input or output and starts the reception.
2. Receive data is shifted into SCRSR in order from the LSB to the MSB. After receiving the data, the SCIF checks the receive data can be loaded from SCRSR into SCFRDR or not. If this check is passed, the RDF flag is set to 1 and the SCIF stores the received data in SCFRDR. If the check is not passed (overrun error is detected), further reception is prevented.
3. After setting RDF to 1, if the receive FIFO data full interrupt enable bit (RIE) is set to 1 in SCSCR, the SCIF requests a receive-data-full interrupt (RXI). If the ORER bit is set to 1 and the receive-data-full interrupt enable bit (RIE) or the receive error interrupt enable bit (REIE) in SCSCR is also set to 1, the SCIF requests a break interrupt (BRI).

Figure 17.15 shows an example of SCIF receive operation.

**Figure 17.15 Example of SCIF Receive Operation**

- Transmitting and Receiving Serial Data Simultaneously (Clocked Synchronous Mode)

Figure 17.16 shows a sample flowchart for transmitting and receiving serial data simultaneously. Use the following procedure for the simultaneous transmission/reception of serial data, after enabling the SCIF for transmission/reception.

**Figure 17.16 Sample Flowchart for Transmitting/Receiving Serial Data**

## 17.5 SCIF Interrupts

The SCIF has four interrupt sources: transmit-FIFO-data-empty (TXI), receive-error (ERI), receive FIFO data full (RXI), and break (BRI).

Table 17.17 shows the interrupt sources and their order of priority. The interrupt sources are enabled or disabled by means of the TIE, RIE, and REIE bits in SCSCR. A separate interrupt request is sent to the interrupt controller for each of these interrupt sources.

When a TXI request is enabled by the TIE bit and the TDFE flag in the serial status register (SCFSR) is set to 1, a TXI interrupt request is generated. The DMAC or DTC can be activated and data transfer performed by this TXI interrupt request. At DMAC activation, an interrupt request is not sent to the CPU.

When an RXI request is enabled by the RIE bit and the RDFE flag or the DR flag in SCFSR is set to 1, an RXI interrupt request is generated. The DMAC or DTC can be activated and data transfer performed by this RXI interrupt request. At DMAC activation, an interrupt request is not sent to the CPU. The RXI interrupt request caused by the DR flag is generated only in asynchronous mode.

When the RIE bit is set to 0 and the REIE bit is set to 1, the SCIF requests only an ERI interrupt without requesting an RXI interrupt.

The TXI interrupt indicates that transmit data can be written, and the RXI interrupt indicates that there is receive data in SCFRDR.

**Table 17.17 SCIF Interrupt Sources**

| Interrupt Source | Description                                                            | DMAC or DTC Activation | Priority on Reset Release                                                           |
|------------------|------------------------------------------------------------------------|------------------------|-------------------------------------------------------------------------------------|
| BRI              | Interrupt initiated by break (BRK) or overrun error (ORER)             | Not possible           |  |
| ERI              | Interrupt initiated by receive error (ER)                              | Not possible           |                                                                                     |
| RXI              | Interrupt initiated by receive FIFO data full (RDF) or data ready (DR) | Possible               |                                                                                     |
| TXI              | Interrupt initiated by transmit FIFO data empty (TDFE)                 | Possible               |                                                                                     |

## 17.6 Usage Notes

Note the following when using the SCIF.

### 17.6.1 SCFTDR Writing and TDFE Flag

The TDFE flag in the serial status register (SCFSR) is set when the number of transmit data bytes written in the transmit FIFO data register (SCFTDR) has fallen below the transmit trigger number set by bits TTRG[1:0] in the FIFO control register (SCFCR). After the TDFE flag is set, transmit data up to the number of empty bytes in SCFTDR can be written, allowing efficient continuous transmission.

However, if the number of data bytes written in SCFTDR is equal to or less than the transmit trigger number, the TDFE flag will be set to 1 again after being read as 1 and cleared to 0. TDFE flag clearing should therefore be carried out when SCFTDR contains more than the transmit trigger number of transmit data bytes.

The number of transmit data bytes in SCFTDR can be found from the upper 8 bits of the FIFO data count register (SCFDR).

### 17.6.2 SCFRDR Reading and RDF Flag

The RDF flag in the serial status register (SCFSR) is set when the number of receive data bytes in the receive FIFO data register (SCFRDR) has become equal to or greater than the receive trigger number set by bits RTRG[1:0] in the FIFO control register (SCFCR). After RDF flag is set, receive data equivalent to the trigger number can be read from SCFRDR, allowing efficient continuous reception.

However, if the number of data bytes in SCFRDR exceeds the trigger number, the RDF flag will be set to 1 again if it is cleared to 0. The RDF flag should therefore be cleared to 0 after being read as 1 after reading the number of the received data in the receive FIFO data register (SCFRDR) which is less than the trigger number.

The number of receive data bytes in SCFRDR can be found from the lower 8 bits of the FIFO data count register (SCFDR).

### 17.6.3 Restriction on DMAC and DTC Usage

When the DMAC or DTC writes data to SCFTDR due to a TXI interrupt request, the state of the TEND flag becomes undefined. Therefore, the TEND flag should not be used as the transfer end flag in such a case.

### 17.6.4 Break Detection and Processing

Break signals can be detected by reading the RXD pin directly when a framing error (FER) is detected. In the break state the input from the RXD pin consists of all 0s, so the FER flag is set and the parity error flag (PER) may also be set.

Note that, although transfer of receive data to SCFRDR is halted in the break state, the SCIF receiver continues to operate.

### 17.6.5 Sending a Break Signal

The I/O condition and level of the TXD pin are determined by the SPB2IO and SPB2DT bits in the serial port register (SCSPTR). This feature can be used to send a break signal.

Until TE bit is set to 1 (enabling transmission) after initializing, the TXD pin does not work. During the period, mark status is performed by the SPB2DT bit. Therefore, the SPB2IO and SPB2DT bits should be set to 1 (high level output).

To send a break signal during serial transmission, clear the SPB2DT bit to 0 (designating low level), then clear the TE bit to 0 (halting transmission). When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, and 0 is output from the TXD pin.

### 17.6.6 Receive Data Sampling Timing and Receive Margin (Asynchronous Mode)

The SCIF operates on a base clock with a frequency of 16 times the transfer rate.\* In reception, the SCIF synchronizes internally with the fall of the start bit, which it samples on the base clock. Receive data is latched at the rising edge of the eighth base clock pulse. The timing is shown in figure 17.17.

Note: \* This is an example when  $ABCS = 0$  in SCSEMR. When  $ABCS = 1$ , a frequency of 8 times the bit rate becomes the basic clock, and receive data is sampled at the fourth rising edge of the basic clock.

**Figure 17.17 Receive Data Sampling Timing in Asynchronous Mode**

The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

### Equation 1:

$$M = \left| \left( 0.5 - \frac{1}{2N} \right) - (L - 0.5) F - \frac{|D - 0.5|}{N} (1 + F) \right| \times 100 \%$$

Where: M: Receive margin (%)

N: Ratio of clock frequency to bit rate (N = 16)

D: Clock duty (D = 0 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

### Equation 2:

When D = 0.5 and F = 0:

$$\begin{aligned} M &= (0.5 - 1/(2 \times 16)) \times 100\% \\ &= 46.875\% \end{aligned}$$

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

## 17.6.7 FER Flag and PER Flag of Serial Status Register (SCFSR)

The FER flag and PER flag in the serial status register (SCFSR) are status flag that apply to next entry to be read from the receive FIFO data register (SCFRDR). After the CPU or DTC/DMAC reads the receive FIFO data register, the flags of framing errors and parity errors will disappear.

To check the received data for the states of framing errors and parity errors, only read the receive FIFO register after reading the serial status register.

## Section 18 Renesas Serial Peripheral Interface (RSPI)

This LSI includes a channel of Renesas Serial Peripheral Interface (RSPI).

The RSPI is capable of full-duplex synchronous, high-speed serial communications with multiple processors and peripheral devices.

### 18.1 Features

The RSPI of this LSI has the following features:

#### 1. RSPI Transfer Function

- Uses MOSI (Master Out Slave In), MISO (Master In Slave Out), SSL (Slave Select), and RSPCK (RSPI Clock) signals to provide SPI mode (four-wire) and clock synchronous mode (three-wire) serial communications.
- Capable of master-slave mode serial communication.
- Capable of mode fault error detection.
- Capable of overrun error detection.
- Modifiable serial transfer clock polarity.
- Modifiable serial transfer clock phase.

#### 2. Data Format

- Switchable MSB first/LSB first.
- Transfer bit length changeable to 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, and 32 bits.
- Transmission/receive buffers of 128 bits
- Up to 4 frames (up to 32 bits per frame) can be transferred at a time in transmission or reception.

#### 3. Bit Rate

- In master mode:  
An internal baud rate generator generates RSPCK by dividing  $P\phi$  by up to 4906.
- In slave mode:  
The serial clock signal is generated with division by up to 8.  
An external input clock is used as the serial clock.

#### 4. Buffer Configuration

- Transmission/receive buffers are provided in a double-buffer configuration.

#### 5. SSL Control Function

- Provided with four SSL signals (SSL0 to SSL3).
- In single-master mode, SSL0 to SSL3 signals are for output.
- In multi-master mode, SSL0 signal is for input, and SSL1 to SSL3 signals are for either output or Hi-Z.
- In slave mode, SSL0 signal is for input, and SSL1 to SSL3 signals are for Hi-Z.
- A delay from SSL output assertion to RSPCK operation (RSPCK delay) can be set.  
Settable range: 1 to 8 RSPCK cycles  
Unit: 1 RSPCK cycle
- A delay from RSPCK stop to SSL output negation (SSL negation delay) can be set.  
Settable range: 1 to 8 RSPCK cycles  
Unit: 1 RSPCK cycle
- Wait for next-access SSL output assertion (next-access delay) can be set.  
Settable range: 1 to 8 RSPCK cycles  
Unit: 1 RSPCK cycle
- Switchable SSL polarity.

#### 6. Master Mode Transfer Control Method

- A transfer comprised of a maximum of four commands can be executed in sequential loops.
- Each command can include:  
SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, LSB/MSB first, burst, RSPCK delay, SSL negation delay, and next-access delay.
- A transfer can be started upon writing to the transmit buffer by the DMAC.
- A transfer can be started upon writing to the transmit buffer by the DTC.
- A transfer can be started upon clearing the SPTEF bit by the CPU.
- MOSI signal values can be set during SSL negation.

## 7. Interrupt Sources

- Maskable interrupt sources are provided.
  - RSPI receive interrupt (receive buffer full)
  - RSPI transmit interrupt (transmit buffer empty)
  - RSPI error interrupt (mode fault and overrun)

## 8. Other Features

- Loopback mode is provided.
- The CMOS/open drain output switchover function is provided.
- The RSPI disable (initialization) function is provided.

### 18.1.1 Internal Block Diagram

Figure 18.1 shows an RSPI block diagram.

Figure 18.1 Block Diagram of RSPI

## 18.2 Input/Output Pins

The RSPi has the serial pins shown in table 18.1. The RSPi automatically switches input/output directions of the pins. Pin SSL0 is set to output when the RSPi is in single master mode and set to input when the RSPi is in multi master or slave mode. Pins RSPCK, MOSI, and MISO are set to inputs or outputs according to the master/slave setting and input level of SSL0 (see section 18.4.2, Controlling RSPi Pins).

**Table 18.1 Pin Configuration**

| Pin Name                 | Symbol | I/O    | Function                  |
|--------------------------|--------|--------|---------------------------|
| RSPi clock pin           | RSPCK  | I/O    | RSPi clock input/output   |
| Master transmit data pin | MOSI   | I/O    | RSPi master transmit data |
| Slave transmit data pin  | MISO   | I/O    | RSPi slave transmit data  |
| Slave select 0 pin       | SSL0   | I/O    | RSPi slave select         |
| Slave select 1 pin       | SSL1   | Output | RSPi slave select         |
| Slave select 2 pin       | SSL2   | Output | RSPi slave select         |
| Slave select 3 pin       | SSL3   | Output | RSPi slave select         |

Note: Pin names RSPCK, MOSI, MISO, and SSL0 to SSL3 are used in the description for all channels, omitting the channel designation.

## 18.3 Register Descriptions

The RSPI has the registers shown in table 18.2. These registers enable the RSPI to perform the following controls: specifying master/slave modes, specifying a transfer format, and controlling the transmitter and receiver.

**Table 18.2 Register Configuration**

| Register Name                             | Symbol | R/W | Initial Value | Address    | Access Size |
|-------------------------------------------|--------|-----|---------------|------------|-------------|
| RSPI control register                     | SPCR   | R/W | H'00          | H'FFFFB000 | 8, 16       |
| RSPI slave select polarity register       | SSLP   | R/W | H'00          | H'FFFFB001 | 8           |
| RSPI pin control register                 | SPPCR  | R/W | H'00          | H'FFFFB002 | 8, 16       |
| RSPI status register                      | SPSR   | R/W | H'22          | H'FFFFB003 | 8           |
| RSPI data register                        | SPDR   | R/W | H'00000000    | H'FFFFB004 | 16, 32*     |
| RSPI sequence control register            | SPSCR  | R/W | H'00          | H'FFFFB008 | 8, 16       |
| RSPI sequence status register             | SPSSR  | R   | H'00          | H'FFFFB009 | 8           |
| RSPI bit rate register                    | SPBR   | R/W | H'FF          | H'FFFFB00A | 8, 16       |
| RSPI data control register                | SPDCR  | R/W | H'00          | H'FFFFB00B | 8           |
| RSPI clock delay register                 | SPCKD  | R/W | H'00          | H'FFFFB00C | 8, 16       |
| RSPI slave select negation delay register | SSLND  | R/W | H'00          | H'FFFFB00D | 8           |
| RSPI next-access delay register           | SPND   | R/W | H'00          | H'FFFFB00E | 8           |
| RSPI command register 0                   | SPCMD0 | R/W | H'070D        | H'FFFFB010 | 16          |
| RSPI command register 1                   | SPCMD1 | R/W | H'070D        | H'FFFFB012 | 16          |
| RSPI command register 2                   | SPCMD2 | R/W | H'070D        | H'FFFFB014 | 16          |
| RSPI command register 3                   | SPCMD3 | R/W | H'070D        | H'FFFFB016 | 16          |

Notes: \* Use the access size set by the SPLW bit.

### 18.3.1 RSPI Control Register (SPCR)

SPCR sets the operating mode of the RSPI. SPCR can be read from or written to by the CPU. If the MSTR and MODFEN bits are changed while the RSPI function is enabled by setting the SPE bit to 1, subsequent operations cannot be guaranteed.

|                |       |     |       |       |      |        |   |      |
|----------------|-------|-----|-------|-------|------|--------|---|------|
| Bit:           | 7     | 6   | 5     | 4     | 3    | 2      | 1 | 0    |

### 18.3.2 RSPI Slave Select Polarity Register (SSLP)

SSLP sets the polarity of the SSL0 to SSL7 signals of the RSPI. SSLP can always be read from or written to by the CPU. If the contents of SSLP are changed by the CPU while the RSPI function is enabled by setting the SPE bit in the RSPI control register (SPCR) to 1, subsequent operations cannot be guaranteed.

|                |     |     |     |     |       |       |       |       |
|----------------|-----|-----|-----|-----|-------|-------|-------|-------|
| Bit:           | 7   | 6   | 5   | 4   | 3     | 2     | 1     | 0     |

|        |          |               |     | 0: SSLi signal set to active-0<br>1: SSLi signal set to active-1                                                            |

### 18.3.3 RSPI Pin Control Register (SPPCR)

SPPCR sets the modes of the RSPI pins. SPPCR can be read from or written to by the CPU. If the contents of this register are changed by the CPU while the RSPI function is enabled by setting the SPE bit in the RSPI control register (SPCR) to 1, operation cannot be guaranteed.

### 18.3.4 RSPI Status Register (SPSR)

SPSR indicates the operating status of the RSPI. SPSR can be read by the CPU. Writing 1 to the SPRF, SPTEF, MODF, and OVRF bits cannot be performed by the CPU. These bits can be cleared to 0 after they are read as 1.

### 18.3.5 RSPI Data Register (SPDR)

SPDR is a buffer that stores RSPI transmit/receive data. The transmit buffer (SPTX) and receive buffer (SPRX) are allocated for SPDR and these buffers are independent of each other.

Data should be read from or written to SPDR in word or longword units according to the setting of the RSPI longword/word access setting bit (SPLW) in the RSPI data control register (SPDCR). When the SPLW bit is 0, SPDR is a 64-bit buffer consisting of 4 frames, each of which includes up to 16 bits. When the SPLW bit is 1, SPDR is a 128-bit buffer consisting of 4 frames, each of which includes up to 32 bits.

This register acts as the interface with the FIFO buffer. To read four frames of data, reading SPDR four times will lead to the data being read out in the order of reception. To transmit four frames of data, write to SPDR four times.

The frame length that SPDR uses is determined by the frame count setting bits (SPFC1 and SPFC0) in the RSPI data control register (SPDCR). The bit length to be used is determined by the RSPI data length setting bits (SPB3 to SPB0) in the RSPI command register (SPCMD).

If the CPU, DTC, or DMAC requests writing to SPDR when the SPTEF bit in the RSPI status register (SPSR) is 1, the RSPI writes data to the transmit buffer of SPDR. If the SPTEF bit is 0, the RSPI does not update the transmit buffer of SPDR.

When the CPU, DTC, or DMAC requests reading from SPDR, data is read from the receive buffer if the RSPI receive/transmit data select bit (SPRDTD) in the RSPI pin control register (SPPCR) is 0, or data is read from the transmit buffer if the SPRDTD bit is 1.

When reading data from the transmit buffer, the most recently written value is read. If the SPTEF bit in the RSPI status register (SPSR) is 0, no data is read from the transmit buffer.

In the normal operating method, the CPU, DTC, and DMAC read the receive buffer when the SPRF bit in SPSR is 1 (a condition in which unread data is stored in the receive buffer). When the SPRF or OVRF bit in SPSR is 1, the RSPI does not update the receive buffer of SPDR at the end of a serial transfer.

### 18.3.6 RSPI Sequence Control Register (SPSCR)

SPSCR sets the sequence control method when the RSPI operates in master mode. SPSCR can be read from or written to by the CPU. If the contents of SPSCR are changed by the CPU while the MSTR and SPE bits in the RSPI control register (SPCR) are 1 with the RSPI function enabled, the subsequent operation cannot be guaranteed.

### 18.3.7 RSPI Sequence Status Register (SPSSR)

SPSSR indicates the sequence control status when the RSPI operates in master mode. SPSSR can be read by the CPU. Any writing to SPSSR by the CPU is ignored.

### 18.3.8 RSPI Bit Rate Register (SPBR)

SPBR sets the bit rate in master mode. SPBR can be read from or written to by the CPU. If the contents of SPBR are changed by the CPU while the MSTR and SPE bits in the RSPI control register (SPCR) are 1 with the RSPI function in master mode enabled, operation cannot be guaranteed. When the RSPI is used in slave mode, the bit rate depends on the input clock regardless of the settings of SPBR and BRDV.

|                |      |      |      |      |      |      |      |      |
|----------------|------|------|------|------|------|------|------|------|
| Bit:           | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|                | SPR7 | SPR6 | SPR5 | SPR4 | SPR3 | SPR2 | SPR1 | SPR0 |
| Initial value: | 1    | 1    | 1    | 1    | 1    | 1    | 1    | 1    |
| R/W:           | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  |

The bit rate is determined by combinations of SPBR settings and the bit settings in the BRDV1 and BRDV0 bits in the RSPI command registers (SPCMD0 to SPCMD7). The equation for calculating the bit rate is given below. In the equation, N denotes an SPBR setting (0, 1, 2, ..., 255), and n denotes bit settings in the bits BRDV1 and BRDV0 (0, 1, 2, 3).

$$\text{Bit rate} = \frac{f(P\phi)}{2 \times (N + 1) \times 2^n}$$

Table 18.3 shows examples of the relationship between the SPBR register and BRDV1 and BRDV0 bit settings.

**Table 18.3 Relationship between SPBR and BRDV[1:0] Settings**

| SPBR<br>(N) | BRDV[1:0]<br>(n) | Division<br>Ratio | Bit Rate          |                   |                   |                   |                   |

### 18.3.9 RSPI Data Control Register (SPDCR)

RSPI sets the number of frames that can be stored in the SPDR register, specifies from which buffer of the SPDR register data should be read, and sets the access size, word or longword, for the SPDR register.

Up to 4 frames can be transmitted or received at a time upon transmission or reception activation according to the setting combinations of the RSPI data length setting bits (SPB3 to SPB0) in the RSPI command register (SPCMD), RSPI sequence length setting bits (SPSLN1 and SPSLN0) in the RSPI sequence control register (SPSCR), and frame count setting bits (SPFC1 and SPFC0) in the RSPI data control register (SPDCR).

SPDCR can be read from or written to by the CPU. If the contents of SPDCR are changed by the CPU while the RSPI function is enabled with the SPE bit in the RSPI control register (SPCR) set to 1, subsequent operations cannot be guaranteed.

### 18.3.10 RSPI Clock Delay Register (SPCKD)

SPCKD sets a period from the beginning of SSL signal assertion to RSPCK oscillation (RSPCK delay) when the SCKDEN bit in the RSPI command register (SPCMD) is 1. SPCKD can be read from or written to by the CPU. If the contents of SPCKD are changed by the CPU while the MSTR and SPE bits in the RSPI control register (SPCR) are 1 with the RSPI function in master mode enabled, operation cannot be guaranteed.

When using the RSPI in slave mode, set 000 in SCKDL[2:0].

|                |   |   |   |   |   |            |     |     |

### 18.3.11 SPI Slave Select Negation Delay Register (SSLND)

SSLND sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSL signal during a serial transfer by the RSPI in master mode. SSLND can be read from or written to by the CPU. If the contents of SSLND are changed by the CPU while the MSTR and SPE bits in the RSPI control register (SPCR) are 1 with the RSPI function in master mode enabled, operation cannot be guaranteed.

When using the RSPI in slave mode, set 000 in SLNDL[2:0].

### 18.3.12 RSPI Next-Access Delay Register (SPND)

SPND sets a non-active period (next-access delay) after termination of a serial transfer when the SPNDEN bit in the RSPI command register (SPCMD) is 1. SPND can be read from or written to by the CPU. If the contents of SPND are changed by the CPU while the MSTR and SPE bits in the RSPI control register (SPCR) are 1 with the RSPI function in master mode enabled, operation cannot be guaranteed.

When using the RSPI in slave mode, set 000 in SPNDL[2:0].

### 18.3.13 RSPI Command Register (SPCMD)

The RSPI has four RSPI command registers (SPCMD0 to SPCMD3). SPCMD0 to SPCMD3 are used to set a transfer format for the RSPI in master mode. Some of the bits in SPCMD0 are used to set a transfer mode for the RSPI in slave mode. The RSPI in master mode sequentially references SPCMD0 to SPCMD3 according to the settings in bits SPSLN1 and SPSLN0 in the RSPI sequence control register (SPSCR), and executes the serial transfer that is set in the referenced SPCMD.

SPCMD can be read from or written to by the CPU.

Set the SPCMD register before setting data to be transferred referencing the SPCMD settings while the SPTEF bit in the RSPI status register (SPSR) is 1.

SPCMD that is referenced by the RSPI in master mode can be checked by means of bits SPCPI and SPCP0 in the RSPI sequence status register (SPSSR). When the RSPI function in slave mode is enabled, operation cannot be guaranteed if the value set in SPCMD0 is changed by the CPU.

| 3, 2 | BRDV[1:0] | 11            | R/W | <p>Bit Rate Division Setting</p> <p>These bits are used to determine the bit rate. A bit rate is determined by combinations of bits BRDV1 and BRDV 0 and the settings in the RSPI bit rate register (SPBR). The settings in SPBR determine the base bit rate. The settings in bits BRDV1 and BRDV0 are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. For SPCMD0 to SPCMD3, different BRDV1 and BRDV0 settings can be specified. This permits the execution of serial transfers at a different bit rate for each command.</p> <p>00: Select the base bit rate</p> <p>01: Select the base bit rate divided by 2</p> <p>10: Select the base bit rate divided by 4</p> <p>11: Select the base bit rate divided by 8</p> |

## 18.4 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

### 18.4.1 Overview of RSPI Operations

The RSPI is capable of synchronous serial transfers in slave (SPI), single-master (SPI), and multi-master (SPI), slave (clock synchronous), and master (clock synchronous) modes. A particular mode of the RSPI can be selected by using the MSTR, MODFEN, and SPMS bits in the RSPI control register (SPCR). Table 18.5 gives the relationship between RSPI modes and SPCR settings, and a description of each mode.

**Table 18.5 Relationship between RSPI Modes and SPCR and Description of Each Mode**

| Item                               | Slave (SPI)         | Single-Master (SPI)         | Multi-Master (SPI)          | Slave (Clock Synchronous) | Master (Clock Synchronous)  |
|------------------------------------|---------------------|-----------------------------|-----------------------------|---------------------------|-----------------------------|
| MSTR bit setting                   | 0                   | 1                           | 1                           | 0                         | 1                           |
| MODFEN bit setting                 | 0, 1                | 0                           | 1                           | 0                         | 0                           |
| SPMS bit setting                   | 0                   | 0                           | 0                           | 1                         | 1                           |

## 18.4.2 Controlling RSPI Pins

According to the MSTR, MODFEN and SPMS bits in the RSPI control register (SPCR) and the SPOM bit in the RSPI pin control register (SPPCR), the RSPI can automatically switch pin directions and output modes. Table 18.6 shows the relationship between pin states and bit settings.

**Table 18.6 Relationship between Pin States and Bit Settings**

| Mode                                                                 | Pin                        | Pin State* <sup>1</sup> |                        |
|----------------------------------------------------------------------|----------------------------|-------------------------|------------------------|
|                                                                      |                            | SPOM = 0                | SPOM = 1               |

|                                                                      | SSL0 to SSL3* <sup>4</sup> | Hi-Z                    | Hi-Z                   |
|                                                                      | MOSI                       | CMOS output             | Open-drain output      |
|                                                                      | MISO                       | Input                   | Input                  |
|                                                                      | RSPCK                      | CMOS output             | Open-drain output      |
|                                                                      | SSL0 to SSL3* <sup>4</sup> | Hi-Z                    | Hi-Z                   |

| Mode                                              | Pin                        | Pin State* <sup>1</sup> |                   |
|---------------------------------------------------|----------------------------|-------------------------|-------------------|
|                                                   |                            | SPOM = 0                | SPOM = 1          |
| Slave (clock synchronous)<br>(MSTR = 0, SPMS = 1) | RSPCK                      | Input                   | Input             |
|                                                   | SSL0 to SSL3* <sup>4</sup> | Hi-Z                    | Hi-Z              |
|                                                   | MOSI                       | Input                   | Input             |
|                                                   | MISO                       | CMOS output             | Open-drain output |

Notes: 1. RSPI settings are not reflected to the multi-function pins for which the RSPI function is not applied.

2. When SSL0 is at the active level, the pin state is Hi-Z.

3. When SSL0 is at the active level or the SPE bit in SPCR is 0, the pin state is Hi-Z.

4. SSL0 to SSL3 can be used as the IO ports in clock synchronous mode.

The RSPI in single-master (SPI) and multi-master (SPI) modes determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to the settings of the MOIFE and MOIFV bits in SPPCR as shown in table 18.7.

**Table 18.7 MOSI Signal Value Determination during SSL Negation Period**

| MOIFE | MOIFV | MOSI Signal Value during SSL Negation Period* |
|-------|-------|-----------------------------------------------|
| 0     | 0, 1  | Final data from previous transfer             |
| 1     | 0     | Always 0                                      |
| 1     | 1     | Always 1                                      |

Note: \* The SSL negation period includes the SSL retention period during a burst transfer.

### 18.4.3 RSPI System Configuration Example

#### (1) Single Master/Single Slave (with This LSI Acting as Master)

Figure 18.2 shows a single-master/single-slave RSPI system configuration example when this LSI is used as a master. In the single-master/single-slave configuration, the SSL0 to SSL3 outputs of this LSI (master) are not used. The SSL input of the RSPI slave is fixed to 0, and the RSPI slave is always maintained in a select state. In the transfer format corresponding to the case where the CPHA bit in the RSPI control register (SPCR) is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSL output of this LSI should be connected to the SSL input of the slave device.

This LSI (master) always drives the RSPCK and MOSI signals. The RSPI slave always drives the MISO signal.

**Figure 18.2 Single-Master/Single-Slave Configuration Example (This LSI = Master)**

## (2) Single Master/Single Slave (with This LSI Acting as Slave)

Figure 18.3 shows a single-master/single-slave RSPi system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave, the SSL0 pin is used as SSL input. The RSPi master always drives the RSPCK and MOSI signals. This LSI (slave) always drives the MISO signal\*.

In the single-slave configuration in which the CPHA bit in the RSPi command register (SPCMD) is set to 1, the SSL0 input of this LSI (slave) is fixed to 0, this LSI (slave) is always maintained in a selected state, and in this manner it is possible to execute serial transfer (figure 18.4).

Note: \* When SSL0 is at the active level, the pin state becomes Hi-Z.

**Figure 18.3 Single-Master/Single-Slave Configuration Example (This LSI = Slave)**

**Figure 18.4 Single-Master/Single-Slave Configuration Example  
(This LSI = Slave, CPHA = 1)**

### (3) Single Master/Multi-Slave (with This LSI Acting as Master)

Figure 18.5 shows a single-master/multi-slave RSPi system configuration example when this LSI is used as a master. In the example of figure 18.5, the RSPi system is comprised of this LSI (master) and four slaves (RSPi slave 0 to RSPi slave 3).

The RSPCK and MOSI outputs of this LSI (master) are connected to the RSPCK and MOSI inputs of RSPi slave 0 to RSPi slave 3. The MISO outputs of RSPi slave 0 to RSPi slave 3 are all connected to the MISO input of this LSI (master). SSL0 to SSL3 outputs of this LSI (master) are connected to the SSL inputs of RSPi slave 0 to RSPi slave 3, respectively.

This LSI (master) always drives the RSPCK, MOSI, and SSL0 to SSL3 signals. Of the RSPi slave 0 to RSPi slave 3, the slave that receives 0 into the SSL input drives the MISO signal.

**Figure 18.5 Single-Master/Multi-Slave Configuration Example (This LSI = Master)**

#### (4) Single Master/Multi-Slave (with This LSI Acting as Slave)

Figure 18.6 shows a single-master/multi-slave RSPi system configuration example when this LSI is used as a slave. In the example of figure 18.6, the RSPi system is comprised of an RSPi master and these two LSIs (slave X and slave Y).

The RSPCK and MOSI outputs of the RSPi master are connected to the RSPCK and MOSI inputs of these LSIs (slave X and slave Y). The MISO outputs of these LSIs (slave X and slave Y) are all connected to the MISO input of the RSPi master. SSLX and SSLY outputs of the RSPi master are connected to the SSL0 inputs of the LSIs (slave X and slave Y), respectively.

The RSPi master always drives the RSPCK, MOSI, SSLX, and SSLY signals. Of these LSIs (slave X and slave Y), the slave that receives low level input into the SSL0 input drives the MISO signal.

**Figure 18.6 Single-Master/Multi-Slave Configuration Example (This LSI = Slave)**

### (5) Multi-Master/Multi-Slave (with This LSI Acting as Master)

Figure 18.7 shows a multi-master/multi-slave RSPI system configuration example when this LSI is used as a master. In the example of figure 18.7, the RSPI system is comprised of these two LSIs (master X, master Y) and two RSPI slaves (RSPI slave 1, RSPI slave 2).

The RSPCK and MOSI outputs of this LSI (master X, master Y) are connected to the RSPCK and MOSI inputs of RSPI slaves 1 and 2. The MISO outputs of RSPI slaves 1 and 2 are connected to the MISO inputs of this LSI (master X, master Y). Any generic port Y output from this LSI (master X) is connected to the SSL0 input of this LSI (master Y). Any generic port X output of this LSI (master Y) is connected to the SSL0 input of this LSI (master X). The SSL1 and SSL2 outputs of this LSI (master X, master Y) are connected to the SSL inputs of the RSPI slaves 1 and 2. In this configuration example, because the system can be comprised solely of SSL0 input, and SSL1 and SSL2 outputs for slave connections, the output SSL3 of this LSI is not required.

This LSI drives the RSPCK, MOSI, SSL1, and SSL2 signals when the SSL0 input level is 1. When the SSL0 input level is 0, this LSI detects a mode fault error, sets RSPCK, MOSI, SSL1, and SSL2 to Hi-Z, and releases the RSPI bus right to the other master. Of the RSPI slaves 1 and 2, the slave that receives 0 into the SSL input drives the MISO signal.

**Figure 18.7 Multi-Master/Multi-Slave Configuration Example (This LSI = Master)**

## (6) Master (Clock Synchronous)/Slave (Clock Synchronous) (with This LSI Acting as Master)

Figure 18.8 shows a master (clock synchronous)/slave (clock synchronous) RSPI system configuration example when this LSI is used as a master. In the master (clock synchronous)/slave (clock synchronous) configuration, the SSL0 to SSL3 outputs of this LSI (master) are not used.

This LSI (master) always drives the RSPCK and MOSI signals. The RSPI slave always drives the MISO signal.

Only in the single-master configuration in which the CPHA bit in the RSPI command register (SPCMD) is set to 1, this LSI (master) can execute serial transfer.

**Figure 18.8 Master (Clock Synchronous)/Slave (Clock Synchronous) Configuration Example (This LSI = Master)**

**(7) Master (Clock Synchronous)/Slave (Clock Synchronous) (with This LSI = Slave)**

Figure 18.9 shows a master (clock synchronous)/slave (clock synchronous) RSPi system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave, this LSI always drives the MISO signal, and the RSPi master always drives the RSPCK and MOSI signals.

Only in the single-slave configuration in which the CPHA bit in the RSPi command register (SPCMD) is set to 1, this LSI (slave) can execute serial transfer.

**Figure 18.9 Master (Clock Synchronous)/Slave (Clock Synchronous) Configuration Example (This LSI = Slave, CPHA = 1)**

## 18.4.4 Transfer Format

### (1) CPHA = 0

Figure 18.10 shows an example transfer format for the serial transfer of 8-bit data when the CPHA bit in the RSPI command register (SPCMD) is 0. Note that clock synchronous operation (with the SPMS bit in the RSPI control register (SPCR) set to 1) is not guaranteed when the CPHA bit is set to 0. In figure 18.10, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The input/output directions of the signals depend on the RSPI settings. For details, see section 18.4.2, Controlling RSPI Pins.

When the CPHA bit is 0, the output of valid data to the MOSI signal and the driving of valid data to the MISO signal commence at an SSL signal assertion timing. The first RSPCK signal change timing that occurs after the SSL signal assertion becomes the first transfer data fetching timing. After this timing, data is sampled at every RSPCK cycle. The change timing for MOSI and MISO signals is always 1/2 RSPCK cycle after the transfer data fetch timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.

t1 denotes a period from an SSL signal assertion to RSPCK oscillation (RSPCK delay). t2 denotes a period from the cessation of RSPCK oscillation to an SSL signal negation (SSL negation delay). t3 denotes a period in which SSL signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPI of this LSI is in master mode, see section 18.4.9, SPI Operation.

**Figure 18.10 RSPI Transfer Format (CPHA = 0)**

## (2) CPHA = 1

Figure 18.11 shows an example transfer format for the serial transfer of 8-bit data when the CPHA bit in the RSPI command register (SPCMD) is 1. Note that when the SPMS bit in the RSPI control register (SPCR) is 1, the SSL signal is not used and only the RSPCK, MOSI, and MISO signals are used for communication. In figure 18.11, RSPCK (CPOL = 0) indicates the RSPCK signal waveform when the CPOL bit in SPCMD is 0; RSPCK (CPOL = 1) indicates the RSPCK signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The input/output directions of the signals depend on RSPI mode (master or slave). For details, see section 18.4.2, Controlling RSPI Pins.

When the CPHA bit is 1, the driving of invalid data to the MISO signals commences at an SSL signal assertion timing. The driving of valid data to the MOSI and MISO signals commences at the first RSPCK signal change timing that occurs after the SSL signal assertion. After this timing, data is updated at every RSPCK cycle. The transfer data fetch timing is always 1/2 RSPCK cycle after the data update timing. The settings in the CPOL bit do not affect the RSPCK signal operation timing; they only affect the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPI of this LSI is in master mode, see section 18.4.9, SPI Operation.

**Figure 18.11 RSPI Transfer Format (CPHA = 1)**

## 18.4.5 Data Format

The RSPI's data format depends on the settings in the RSPI command register (SPCMD). Irrespective of MSB/LSB first, the RSPI treats the assigned data length of data from the LSB of the RSPI data register (SPDR) as transfer data.

### (1) MSB First Transfer (32-Bit Data)

Figure 18.12 shows the operation of the RSPI data register (SPDR) and the shift register when the RSPI performs a 32-bit MSB-first data transfer.

The CPU or the DTC/DMAC writes T31 to T00 to the transmit buffer of SPDR. If the SPTEF bit in the RSPI status register (SPSR) is 0 and the shift register is empty, the RSPI copies the data in the transmit buffer of SPDR to the shift register, and fully populates the shift register. When serial transfer starts, the RSPI outputs data from the MSB (bit 31) of the shift register, and shifts in the data from the LSB (bit 0) of the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R31 to R00 is stored in the shift register. In this state, the RSPI copies the data from the shift register to the receive buffer of SPDR, and empties the shift register.

If another serial transfer is started before the CPU or the DTC/DMAC writes to the transmit buffer of SPDR, received data R31 to R00 is shifted out from the shift register.

**Figure 18.12 MSB First Transfer (32-Bit Data)**

## (2) MSB First Transfer (24-Bit Data)

Figure 18.13 shows the operation of the RSPi data register (SPDR) and the shift register when the RSPi performs a 24-bit data length MSB-first data transfer.

The CPU or the DTC/DMAC writes T31 to T00 to the transmit buffer of SPDR. If the SPTEF bit in the RSPi status register (SPSR) is 0 and the shift register is empty, the RSPi copies the data in the transmit buffer of SPDR to the shift register, and fully populates the shift register. When serial transfer starts, the RSPi outputs data from bit 23 of the shift register, and shifts in the data from the LSB (bit 0) of the shift register. When the RSPCK cycle required for the serial transfer of 24 bits has passed, received data R23 to R00 is stored in bits 23 to 0 of the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 31 to 24 in the shift register. In this state, the RSPi copies the data from the shift register to the receive buffer of SPDR, and empties the shift register.

If another serial transfer is started before the CPU or the DTC/DMAC writes to the transmit buffer of SPDR, received data R23 to R00 is shifted out from the shift register.

**Figure 18.13 MSB First Transfer (24-Bit Data)**

### (3) LSB First Transfer (32-Bit Data)

Figure 18.14 shows the operation of the RSPI data register (SPDR) and the shift register when the RSPI performs a 32-bit data length LSB-first data transfer.

The CPU or the DTC/DMAC writes T31 to T00 to the transmit buffer of SPDR. If the SPTEF bit in the RSPI status register (SPSR) is 0 and the shift register is empty, the RSPI reverses the order of the bits of the data in the transmit buffer of SPDR, copies it to the shift register, and fully populates the shift register. When serial transfer starts, the RSPI outputs data from the MSB (bit 31) of the shift register, and shifts in the data from the LSB (bit 0) of the shift register. When the RSPCK cycle required for the serial transfer of 32 bits has passed, data R00 to R31 is stored in the shift register. In this state, the RSPI copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register.

If another serial transfer is started before the CPU or the DTC/DMAC writes to the transmit buffer of SPDR, received data R00 to R31 is shifted out from the shift register.

**Figure 18.14 LSB First Transfer (32-Bit Data)**

#### (4) LSB First Transfer (24-Bit Data)

Figure 18.15 shows the operation of the RSPI data register (SPDR) and the shift register when the RSPI performs a 24-bit data length LSB-first data transfer.

The CPU or the DTC/DMAC writes T31 to T00 to the transmit buffer of SPDR. If the SPTEF bit in the RSPI status register (SPSR) is 0 and the shift register is empty, the RSPI reverses the order of the bits of the data in the transmit buffer of SPDR, copies it to the shift register, and fully populates the shift register. When serial transfer starts, the RSPI outputs data from the MSB (bit 31) of the shift register, and shifts in the data from bit 8 of the shift register. When the RSPCK cycle required for the serial transfer of 24 bits has passed, received data R00 to R23 is stored in bits 31 to 8 of the shift register. After completion of the serial transfer, data that existed before the transfer is retained in bits 7 to 0 of the shift register. In this state, the RSPI copies the data, in which the order of the bits is reversed, from the shift register to the receive buffer of SPDR, and empties the shift register.

If another serial transfer is started before the CPU or the DTC/DMAC writes to the transmit buffer of SPDR, received data R00 to R23 is shifted out from the shift register.

**Figure 18.15 LSB First Transfer (24-Bit Data)**

### 18.4.6 Transmit Buffer Empty/Receive Buffer Full Flags

Figure 18.16 shows an example of operation of the RSPI transmit buffer empty flag (SPTEF) and the RSPI receive buffer full flag in the RSPI status register (SPSR). The SPDR access depicted in figure 18.16 indicates the condition of access from the DTC/DMAC to the RSPI data register (SPDR), where I denotes an idle cycle, W a write cycle, and R a read cycle. In this example in figure 18.16, the RSPI executes an 8-bit serial transfer with the SPFC[1:0] bits in the RSPI data control register (SPDCR) set to 00, the CPHA bit in the RSPI command register (SPDR) set to 1, and the CPOL bit in SPDR set to 0. The numbers given under the RSPCK waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 18.16 SPTEF and SPRF Bit Operation Example**

The operation of the flags at timings shown in steps (1) to (5) in the figure is described below.

1. When the DTC/DMAC writes transmit data to SPDR when the transmit buffer of SPDR is empty, the RSPI sets the SPTEF bit to 0, and writes data to the transmit buffer, with no change in the SPRF flag.
2. If the shift register is empty, the RSPI sets the SPTEF bit to 1, and copies the data in the transmit buffer to the shift register, with no change in the SPRF flag. How a serial transfer is started depends on the mode of the RSPI. For details, see section 18.4.9, SPI Operation, and section 18.4.10, Clock Synchronous Operation.
3. When the DTC/DMAC writes transmit data to SPDR with the transmit buffer of SPDR being empty, the RSPI sets the SPTEF bit to 1, and writes data to the transmit buffer, while the SPRF flag remains unchanged. Because the data being transferred serially is stored in the shift register, the RSPI does not copy the data in the transmit buffer to the shift register.

4. When the serial transfer ends with the receive buffer of SPDR being empty, the RSPI sets the SPRF bit to 1, and copies the receive data in the shift register to the receive buffer. Because the shift register becomes empty upon completion of serial transfer, if the transmit buffer was full before the serial transfer ended, the RSPI sets the SPTEF bit to 1, and copies the data in the transmit buffer to the shift register. Even when received data is not copied from the shift register to the receive buffer in an overrun error status, upon completion of the serial transfer the RSPI determines that the shift register is empty, and as a result data transfer from the transmit buffer to the shift register is enabled.
5. When the DTC/DMAC reads SPDR with the receive buffer being full, the RSPI sets the SPRF bit to 0, and sends the data in the receive buffer to the bus inside the chip.

If the CPU or the DTC/DMAC writes to SPDR when the SPTEF bit is 0, the RSPI does not update the data in the transmit buffer. When writing to SPDR, make sure that the SPTEF bit is 1. That the SPTEF bit is 1 can be checked by reading SPSR or by using an RSPI transmit interrupt. To use an RSPI transmit interrupt, set the SPTIE bit in SPCR to 1.

If the RSPI is disabled (the SPE bit in SPCR being 0), the SPTEF bit is initialized to 1. For this reason, setting the SPTIE bit to 1 when the RSPI is disabled generates an RSPI transmit interrupt.

When serial transfer ends with the SPRF bit being 1, the RSPI does not copy data from the shift register to the receive buffer, and detects an overrun error (see section 18.4.7, Error Detection). To prevent a receive data overrun error, set the SPRF bit to 0 before the serial transfer ends. That the SPRF bit is 1 can be checked by either reading SPSR or by using an RSPI receive interrupt. To use an RSPI receive interrupt, set the SPRIE bit in SPCR to 1.

### 18.4.7 Error Detection

In the normal RSPI serial transfer, the data written from the RSPI data register (SPDR) to the transmit buffer by either the CPU or the DTC is serially transmitted, and either the CPU or the DTC/DMAC can read the serially received data from the receive buffer of SPDR. If access is made to SPDR by either the CPU or the DTC, depending on the status of the transmit buffer/receive buffer or the status of the RSPI at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.

If a non-normal transfer operation occurs, the RSPI detects the event as an overrun error or a mode fault error. Table 18.8 shows the relationship between non-normal transfer operations and the RSPI's error detection function.

**Table 18.8 Relationship between Non-Normal Transfer Operations and RSPI Error Detection Function**

|   | Occurrence Condition                                                                                   | RSPI Operation                                                                         | Error Detection  |
|---|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|------------------|
| A | Either the CPU or the DTC/DMAC writes to SPDR when the transmit buffer is full.                        | Retains the contents of the transmit buffer. Missing write data.                       | None             |
| B | Serial transfer is started in slave mode when transmit data is still not loaded on the shift register. | Data received in previous serial transfer is serially transmitted.                     | None             |
| C | Either the CPU or the DTC/DMAC reads from SPDR when the receive buffer is empty.                       | Previously received serial data is output to the CPU or the DMAC.                      | None             |
| D | Serial transfer terminates when the receive buffer is full.                                            | Retains the contents of the receive buffer. Missing serial receive data.               | Overrun error    |
| E | The SSL0 input signal is asserted when the serial transfer is idle in multi-master mode.               | RSPI disabled.<br>Driving of the RSPCK, MOSI, and SSL1 to SSL3 output signals stopped. | Mode fault error |

|   | Occurrence Condition                                                           | RSPI Operation                                                                                                                                     | Error Detection  |
|---|--------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| F | The SSL0 input signal is asserted during serial transfer in multi-master mode. | Serial transfer suspended.<br>Missing send/receive data.<br>Driving of the RSPCK, MOSI, and SSL1 to SSL3 output signals stopped.<br>RSPI disabled. | Mode fault error |
| G | The SSL0 input signal is negated during serial transfer in slave mode.         | Serial transfer suspended.<br>Missing send/receive data.<br>Driving of the MISO output signal stopped.<br>RSPI disabled.                           | Mode fault error |

On operation A shown in table 18.8, the RSPI does not detect an error. To prevent data omission during the writing to SPDR by the CPU or the DTC/DMAC, write operations to SPDR should be executed when the SPTEF bit in the RSPI status register (SPSR) is 1.

Likewise, the RSPI does not detect an error on operation B. In a serial transfer that was started before the shift register was updated, the RSPI sends the data that was received in the previous serial transfer, and does not treat the operation indicated in B as an error. Notice that the received data from the previous serial transfer is retained in the receive buffer of SPDR, and thus it can be correctly read by the CPU or the DTC/DMAC (if SPDR is not read before the end of the serial transfer, an overrun error may result).

Similarly, the RSPI does not detect an error on operation C. To prevent the CPU or the DTC/DMAC from reading extraneous data, SPDR read operation should be executed when the SPRF bit in SPSR is 1.

An overrun error shown in D is described in section 18.4.7 (1), Overrun Error. A mode fault error shown in E to G is described in section 18.4.7 (2), Mode Fault Error. On operations of the SPTEF and SPRF bits in SPSR, see section 18.4.6, Transmit Buffer Empty/Receive Buffer Full Flags.

## (1) Overrun Error

If serial transfer ends when the receive buffer of the RSPi data register (SPDR) is full, the RSPi detects an overrun error, and sets the OVRF bit in SPSR to 1. When the OVRF bit is 1, the RSPi does not copy data from the shift register to the receive buffer so that the data prior to the occurrence of the error is retained in the receive buffer. To reset the OVRF bit in SPSR to 0, either execute a system reset, or write a 0 to the OVRF bit after the CPU has read SPSR with the OVRF bit set to 1.

Figure 18.17 shows an example of operation of the SPRF and OVRF bits in SPSR. The SPSR access depicted in figure 18.17 indicates the condition of access from the CPU to SPSR, and from the DTC/DMAC to SPDR, respectively, where I denotes an idle cycle, W a write cycle, and R a read cycle. In the example of figure 18.17, the RSPi performs an 8-bit serial transfer in which the CPHA bit in the RSPi command register (SPCMD) is 1, and CPOL is 0. The numbers given under the RSPCK waveform represent the number of RSPCK cycles (i.e., the number of transferred bits).

**Figure 18.17 SPRF and OVRF Bit Operation Example**

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

1. If a serial transfer terminates with the SPRF bit being 1 (receive buffer full), the RSPi detects an overrun error, and sets the OVRF bit to 1. The RSPi does not copy the data in the shift register to the receive buffer. In master mode, the RSPi copies the value of the pointer to the RSPi command register (SPCMD) to bits SPECM2 to SPECM0 in the RSPi sequence status register (SPSSR).
2. When the DTC/DMAC reads SPDR, the RSPi sets the SPRF bit to 0, and outputs the data in the receive buffer to an internal bus. The receive buffer becoming empty does not clear the OVRF bit.

3. If the serial transfer terminates with the OVRF bit being 1 (an overrun error), the RSPI keeps the SPRF bit at 0 and does not update it. Likewise, the RSPI does not copy the data in the shift register to the receive buffer. When in master mode, the RSPI does not update bits SPECM1 and SPECM0 of SPSSR. If, in an overrun error state, the RSPI does not copy the received data from the shift register to the receive buffer, upon termination of the serial transfer, the RSPI determines that the shift register is empty; in this manner, data transfer is enabled from the transmit buffer to the shift register.
4. If the CPU writes a 0 to the OVRF bit after reading SPSR when the OVRF bit is 1, the RSPI clears the OVRF bit.

The occurrence of an overrun can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. When using an RSPI error interrupt, set the SPEIE bit in the RSPI control register (SPCR) to 1. When executing a serial transfer without using an RSPI error interrupt, measures should be taken to ensure the early detection of overrun errors, such as reading SPSR immediately after SPDR is read. When the RSPI is run in master mode, the pointer value to SPCMD can be checked by reading bits SPECM2 to SPECM0 of SPSSR.

If an overrun error occurs and the OVRF bit is set to 1, normal reception operations cannot be performed until such time as the OVRF bit is cleared. The OVRF bit is cleared to 0 under the following conditions:

- After reading SPSR in a condition in which the OVRF bit is set to 1, the CPU writes a 0 to the OVRF bit.
- System reset

## (2) Mode Fault Error

The RSPI operates in multi-master mode when the MSTR bit is 1, the SPMS bit is 0 and the MODFEN bit is 1 in the RSPI control register (SPCR). If the active level is input with respect to the SSL0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error irrespective of the status of the serial transfer, and sets the MODF bit in the RSPI status register (SPSR) to 1. Upon detecting the mode fault error, the RSPI copies the value of the pointer to the RSPI command register (SPCMD) to bits SPECM2 to SPECM0 in the RSPI sequence status register (SPSSR). The active level of the SSL0 signal is determined by the SSL0P bit in the RSPI slave select polarity register (SSLP).

When the MSTR bit is 0, the RSPI operates in slave mode. The RSPI detects a mode fault error if the MODFEN bit is 1 and the SPMS bit is 0 in the RSPI in slave mode and if the SSL0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

Upon detecting a mode fault error, the RSPI stops the driving of output signals and clears the SPE bit in the SPCR register. When the SPE bit is cleared, the RSPI function is disabled (see section 18.4.8, Initializing RSPI). In multi-master configuration, it is possible to release the master right by using a mode fault error to stop the driving of output signals and the RSPI function.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. When using an RSPI error interrupt, set the SPEIE bit in the RSPI control register (SPCR) to 1. To detect a mode fault error without using an RSPI error interrupt, it is necessary to poll SPSR. When using the RSPI in master mode, one can read bits SPECM2 to SPECM0 of SPSSR to verify the value of the pointer to SPCMD when an error occurs.

When the MODF bit is 1, the RSPI ignores the writing of the value 1 to the SPE bit by the CPU. To enable the RSPI function after the detection of a mode fault error, the MODF bit must be set to 0. The MODF bit is cleared to 0 under the following conditions:

- After reading SPSR in a condition where the MODF bit has turned 1, the CPU writes a 0 to the MODF bit.
- System reset

## 18.4.8 Initializing RSPI

If the CPU writes a 0 to the SPE bit in the RSPI control register (SPCR) or the RSPI clears the SPE bit to 0 because of the detection of a mode fault error, the RSPI disables the RSPI function, and initializes a part of the module function. If a system reset occurs, the RSPI initializes all of the module function. An explanation follows of initialization by the clearing of the SPE bit and initialization by a system reset.

### (1) Initialization by Clearing SPE Bit

When the SPE bit in SPCR is cleared, the RSPI performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals only in slave mode (Hi-Z)
- Initializing the internal state of the RSPI
- Initializing the SPTEF bit in the RSPI status register (SPSR)

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPI. For this reason, the RSPI can be started in the same transfer mode as prior to the initialization if the CPU resets the value 1 to the SPE bit.

The SPRF, OVRF, and MODF bits in SPSR are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPI is initialized, data from the receive buffer can be read in order to check the status of error occurrence during an RSPI transfer.

The SPTEF bit in SPSR is initialized to 1. Therefore, if the SPTIE bit in SPCR is set to 1 after RSPI initialization, an RSPI transmit interrupt is generated. When the RSPI is initialized by the CPU, in order to disable any RSPI transmit interrupt, a 0 should be written to the SPTIE bit simultaneously with the writing of a 0 to the SPE bit. To disable any RSPI transmit interrupt after a mode fault error is detected, use an error handling routine to write a 0 to the SPTIE bit.

### (2) System Reset

The initialization by a system reset completely initializes the RSPI through the initialization of all bits for controlling the RSPI, initialization of the status bits, and initialization of data registers, in addition to the requirements described in (1), Initialization by Clearing SPE Bit.

## 18.4.9 SPI Operation

### (1) Slave Mode Operation

#### (1-1) Starting a Serial Transfer

If the CPHA bit in RSPi command register 0 (SPCMD0) is 0, when detecting an SSL0 input signal assertion, the RSPi needs to start driving valid data to the MISO output signal. For this reason, the asserting of the SSL0 input signal triggers the start of a serial transfer.

If the CPHA bit is 1, when detecting the first RSPCK edge in an SSL0 signal asserted condition, the RSPi needs to start driving valid data to the MISO signal. For this reason, when the CPHA bit is 1, the first RSPCK edge in an SSL0 signal asserted condition triggers the start of a serial transfer.

When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPi changes the status of the shift register to "full", so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPi leaves the status of the shift register intact, in the full state.

Irrespective of CPHA bit settings, the timing at which the RSPi starts driving MISO output signals is the SSL0 signal assertion timing. The data which is output by the RSPi is either valid or invalid, depending on CPHA bit settings.

For details on the RSPi transfer format, see section 18.4.4, Transfer Format. The polarity of the SSL0 input signal depends on the setting of the SSL0P bit in the RSPi slave select polarity register (SSLP).

#### (1-2) Terminating a Serial Transfer

Irrespective of the CPHA bit in RSPi command register 0 (SPCMD0), the RSPi terminates the serial transfer after detecting an RSPCK edge corresponding to the final sampling timing. When the SPRF bit in the RSPi status register (SPSR) is 0 and free space is available in the receive buffer, upon termination of serial transfer the RSPi copies received data from the shift register to the receive buffer of the RSPi data register (SPDR). Irrespective of the value of the SPRF bit, upon termination of a serial transfer the RSPi changes the status of the shift register to "empty". A mode fault error occurs if the RSPi detects an SSL0 input signal negation from the beginning of serial transfer to the end of serial transfer (see section 18.4.7, Error Detection).

The final sampling timing changes depending on the bit length of the transfer data. In slave mode, the RSPi data length depends on the settings in bits SPB3 to SPB0 bits in SPCMD0. The polarity

of the SSL0 input signal depends on the setting in the SSL0P bit in the RSPI slave select polarity register (SSLP). For details on the RSPI transfer format, see section 18.4.4, Transfer Format.

### (1-3) Notes on Single-Slave Operations

If the CPHA bit in RSPI command register 0 (SPCMD0) is 0, the RSPI starts serial transfers when it detects the assertion edge for an SSL0 input signal. In the type of configuration shown in figure 18.4 as an example, if the RSPI is used in single-slave mode, the SSL0 signal is always fixed at active state. Therefore, when the CPHA bit is set to 0, the RSPI cannot correctly start a serial transfer. To correctly execute send/receive operation by the RSPI in a configuration in which the SSL0 input signal is fixed at active state, the CPHA bit should be set to 1. If there is a need for setting the CPHA bit to 0, the SSL0 input signal should not be fixed.

### (1-4) Burst Transfer

If the CPHA bit in RSPI command register 0 (SPCMD0) is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSL0 input signal. If the CPHA bit is 1, the period from the first RSPCK edge to the sampling timing for the reception of the final bit in an SSL0 signal active state corresponds to a serial transfer period. Even when the SSL0 input signal remains at the active level, the RSPI can accommodate burst transfers because it can detect the start of access.

If the CPHA bit is 0, for the reason given in (1-3), Notes on Single-Slave Operations, second and subsequent serial transfers during the burst transfer cannot be executed correctly.

### (1-5) Initialization Flowchart

Figure 18.18 shows an example of initialization flowchart for using the RSPI in slave mode during SPI operation. For a description of how to set up an interrupt controller, the DTC/DMAC, and input/output ports, see the descriptions given in the individual blocks.

**Figure 18.18 Example of Initialization Flowchart in Slave Mode**

## (1-6) Transfer Operation Flowchart (CPHA = 0)

Figure 18.19 shows an example of transfer operation flowchart for using the RSPI in slave mode during SPI operation, when the CPHA bit in RSPI command register 0 (SPCMD0) is 0.

**Figure 18.19 Example of Transfer Operation Flowchart in Slave Mode (CPHA = 0)**

## (1-7) Transfer Operation Flowchart (CPHA = 1)

Figure 18.20 shows an example of transfer operation flowchart for using the RSPI in slave mode during SPI operation, when the CPHA bit in RSPI command register 0 (SPCMD0) is 1.

**Figure 18.20 Example of Transfer Operation Flowchart in Slave Mode (CPHA = 1)**

## (2) Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (see section 18.4.7, Error Detection). When operating in single-master mode (RSPI), the RSPI does not detect mode fault errors whereas the RSPI running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-/multi-master modes.

### (2-1) Starting Serial Transfer

The RSPI updates the data in the transmit buffer when the SPTEF bit in the RSPI status register (SPSR) is 1 and when either the CPU or the DTC/DMAC has written data to the RSPI data register (SPDR). If the shift register is empty in a condition where the SPTEF bit has been cleared to 0 due to the writing of 0 either after the writing to SPDR from the DTC/DMAC or by the writing of 0 after the value 1 is read from the SPTEF bit by the CPU, the RSPI copies the data in the transmit buffer to the shift register and starts a serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to "full", and upon termination of serial transfer, it changes the status of the shift register to "empty". The status of the shift register cannot be referenced from the CPU.

For details on the RSPI transfer format, see section 18.4.4, Transfer Format. The polarity of the SSL output signal depends on the setting in the RSPI slave select polarity register (SSLP).

### (2-2) Terminating a Serial Transfer

Irrespective of the CPHA bit in the RSPI command register (SPCMD), the RSPI terminates the serial transfer after transmitting an RSPCK edge corresponding to the final sampling timing. If the SPRF bit in the RSPI status register (SPSR) is 0 and free space is available in the receive buffer, upon termination of serial transfer the RSPI copies data from the shift register to the receive buffer of the RSPI data register (SPDR).

It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the settings in bits SPB3 to SPB0 in SPCMD. The polarity of the SSL output signal depends on the setting in the RSPI slave select polarity register (SSLP). For details on the RSPI transfer format, see section 18.4.4, Transfer Format.

## (2-3) Sequence Control

The transfer format that is employed in master mode is determined by the RSPI sequence control register (SPSCR), RSPI command registers 0 to 3 (SPCMD0 to SPCMD3), the RSPI bit rate register (SPBR), the RSPI clock delay register (SPCKD), the RSPI slave select negation delay register (SSLND), and the RSPI next-access delay register (SPND).

The SPSCR register is used to determine the sequence configuration for serial transfers that are executed by a master mode RSPI. The following items are set in RSPI command registers SPCMD0 to SPCMD3: SSL output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.

According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3. The RSPI contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading bits SPCP[1:0] in the RSPI sequence status register (SPSSR). When the SPE bit in the RSPI control register (SPCR) is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

**Figure 18.21 Determination Procedure of Serial Transfer Mode in Master Mode**

## (2-4) Burst Transfer

If the SSLKP bit in the RSPI command register (SPCMD) that the RSPI references during the current serial transfer is 1, the RSPI keeps the SSL signal level during the serial transfer until the beginning of the SSL signal assertion for the next serial transfer. If the SSL signal level for the next serial transfer is the same as the SSL signal level for the current serial transfer, the RSPI can execute continuous serial transfers while keeping the SSL signal assertion status (burst transfer).

Figure 18.22 shows an example of an SSL signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 settings. The text below explains the RSPI operations (1) to (7) as depicted in figure 18.22. It should be noted that the polarity of the SSL output signal depends on the settings in the RSPI slave select polarity register (SSLP).

1. Based on SPCMD0, the RSPI asserts the SSL signal and inserts RSPCK delays.
2. The RSPI executes serial transfers according to SPCMD0.
3. The RSPI inserts SSL negation delays.
4. Because the SSLKP bit in SPCMD0 is 1, the RSPI keeps the SSL signal value on SPCMD0. This period is sustained for next-access delay of  $\text{SPCMD0} + 2 P\phi$  at a minimum. If the shift register is empty after the passage of a minimum period, this period is sustained until such time as the transmit data is stored in the shift register for another transfer.
5. Based on SPCMD1, the RSPI asserts the SSL signal and inserts RSPCK delays.
6. The RSPI executes serial transfers according to SPCMD1.
7. Because the SSLKP bit in SPCMD1 is 0, the RSPI negates the SSL signal. In addition, a next-access delay is inserted according to SPCMD1.

**Figure 18.22 Example of Burst Transfer Operation using SSLKP Bit**

If the SSL signal settings in the SPCMD in which 1 is assigned to the SSLKP bit are different from the SSL signal output settings in the SPCMD to be used in the next transfer, the RSPI switches the SSL signal status to SSL signal assertion ((5) in figure 18.22) corresponding to the command for the next transfer. Notice that if such an SSL signal switching occurs, the slaves that drive the MISO signal compete, and the possibility arises of the collision of signal levels.

The RSPI in master mode references within the module the SSL signal operation for the case where the SSLKP bit is not used. Even when the CPHA bit in SPCMD is 0, the RSPI can accurately start serial transfers by asserting the SSL signal for the next transfer. For this reason, burst transfers in master mode can be executed irrespective of CPHA bit settings (see section 18.4.9, SPI Operation).

#### (2-5) RSPCK Delay (t1)

The RSPCK delay value of the RSPI in master mode depends on SCKDEN bit settings in the RSPI command register (SPCMD) and on RSPCK delay register (SPCKD) settings. The RSPI determines the SPCMD to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SCKDEN bit in the selected SPCMD and SPCKD, as shown in table 18.9. For a definition of RSPCK delay, see section 18.4.4, Transfer Format.

**Table 18.9 Relationship among SCKDEN and SPCKD Settings and RSPCK Delay Values**

| SCKDEN | SPCKD      | RSPCK Delay Value |
|--------|------------|-------------------|
| 0      | 000 to 111 | 1 RSPCK           |
| 1      | 000        | 1 RSPCK           |
|        | 001        | 2 RSPCK           |
|        | 010        | 3 RSPCK           |
|        | 011        | 4 RSPCK           |
|        | 100        | 5 RSPCK           |
|        | 101        | 6 RSPCK           |
|        | 110        | 7 RSPCK           |
|        | 111        | 8 RSPCK           |

#### (2-6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPI in master mode depends on SLNDEN bit settings in the RSPI command register (SPCMD) and on SSL negation delay register (SSLND) settings. The RSPI determines the SPCMD to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SLNDEN bit in the selected SPCMD and SSLND, as shown in table 18.10. For a definition of SSL negation delay, see section 18.4.4, Transfer Format.

**Table 18.10 Relationship among SLNDEN and SSLND Settings and SSL Negation Delay Values**

| SLNDEN | SSLND      | SSL Negation Delay Value |
|--------|------------|--------------------------|
| 0      | 000 to 111 | 1 RSPCK                  |
| 1      | 000        | 1 RSPCK                  |
|        | 001        | 2 RSPCK                  |
|        | 010        | 3 RSPCK                  |
|        | 011        | 4 RSPCK                  |
|        | 100        | 5 RSPCK                  |
|        | 101        | 6 RSPCK                  |
|        | 110        | 7 RSPCK                  |
|        | 111        | 8 RSPCK                  |

**(2-7) Next-Access Delay (t3)**

The next-access delay value of the RSPI in master mode depends on SPNDEN bit settings in the RSPI command register (SPCMD) and on next-access delay register (SPND) settings. The RSPI determines the SPCMD to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPNDEN bit in the selected SPCMD and SPND, as shown in table 18.11. For a definition of next-access delay, see section 18.4.4, Transfer Format.

**Table 18.11 Relationship among SPNDEN and SPND Settings and Next-Access Delay Values**

| SPNDEN | SPND       | Next-Access Delay Value |
|--------|------------|-------------------------|
| 0      | 000 to 111 | 1 RSPCK                 |
| 1      | 000        | 1 RSPCK                 |
|        | 001        | 2 RSPCK                 |
|        | 010        | 3 RSPCK                 |
|        | 011        | 4 RSPCK                 |
|        | 100        | 5 RSPCK                 |
|        | 101        | 6 RSPCK                 |
|        | 110        | 7 RSPCK                 |
|        | 111        | 8 RSPCK                 |

## (2-8) Initialization Flowchart

Figure 18.23 shows an example of initialization flowchart for using the RSPi in master mode during SPI operation. For a description of how to set up an interrupt controller, the DTC/DMAC, and input/output ports, see the descriptions given in the individual blocks.

**Figure 18.23 Example of Initialization Flowchart in Master Mode**

## (2-9) Transfer Operation Flowchart

Figure 18.24 shows an example of transfer operation flowchart for using the RSPI in master mode during SPI operation.

Note: When the SSL0 input signal is asserted in multi-master mode, the RSPI detects a mode fault error irrespective of the hardware status. When detecting the error, the RSPI copies the command pointer to the SPECM[1:0] bits in the RSPI sequence status register (SPSSR).

**Figure 18.24 Example of Transfer Operation Flowchart in Master Mode**

### 18.4.10 Clock Synchronous Operation

The RSPI selects clock synchronous operation when the SPMS bit in the RSPI control register (SPCR) is 1. During clock synchronous operation, the SSL pins are not used and the remaining three pins, RSPCK, MOSI, and MISO are used for communication. The SSL pins can be used as IO ports.

Although the SSL pins are not used for communication in clock synchronous operation, the internal operations within the modules are the same as those during SPI operation.

In both master and slave modes, communications can be performed with the same flows as the SPI operation except that mode fault error detection is not supported because the SSL pins are not used.

If the CPHA bit in the RSPI command register (SPCMD) is set in clock synchronous mode, operation cannot be guaranteed.

#### (1) Slave Mode Operation

##### (1-1) Starting a Serial Transfer

When the SPMS bit in the RSPI control register (SPCR) is 1, the first RSPCK edge triggers the start of a serial transfer.

When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPI changes the status of the shift register to "full", so that data cannot be copied from the transmit buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPI leaves the status of the shift register intact, in the full state.

When the SPMS bit is 1, the RSPI always drives the MISO output signal.

For details on the RSPI transfer format, see section 18.4.4, Transfer Format. Note that the SSL0 input signal is not used in clock synchronous operation.

## (1-2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after detecting an RSPCK edge corresponding to the final sampling timing. When the SPRF bit in the RSPI status register (SPSR) is 0 and free space is available in the receive buffer, upon termination of serial transfer the RSPI copies received data from the shift register to the receive buffer of the RSPI data register (SPDR). Irrespective of the value of the SPRF bit, upon termination of a serial transfer the RSPI changes the status of the shift register to "empty". The final sampling timing changes depending on the bit length of the transfer data. In slave mode, the RSPI data length depends on the settings in bits SPB3 to SPB0 bits in SPCMD0. For details on the RSPI transfer format, see section 18.4.4, Transfer Format.

## (1-3) Initialization Flowchart

Figure 18.25 shows an example of initialization flowchart for using the RSPI in slave mode during clock synchronous operation. For a description of how to set up an interrupt controller, the DTC/DMAC, and input/output ports, see the descriptions given in the individual blocks.

**Figure 18.25 Example of Initialization Flowchart in Slave Mode**

## (1-4) Transfer Operation Flowchart (CPHA = 1)

Figure 18.26 shows an example of transfer operation flowchart for the RSPI during clock synchronous operation.

**Figure 18.26 Example of Transfer Operation Flowchart in Slave Mode (CPHA = 1)**

## (2) Master Mode Operation

### (2-1) Starting Serial Transfer

The RSPI updates the data in the transmit buffer when the SPTEF bit in the RSPI status register (SPSR) is 1 and when either the CPU or the DTC/DMAC has written data to the RSPI data register (SPDR). If the shift register is empty in a condition where the SPTEF bit has been cleared to 0 due to the writing of 0 either after the writing to SPDR from the DTC/DMAC or by the writing of 0 after the value 1 is read from the SPTEF bit by the CPU, the RSPI copies the data in the transmit buffer to the shift register and starts a serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to "full", and upon termination of serial transfer, it changes the status of the shift register to "empty". The status of the shift register cannot be referenced from the CPU.

For details on the RSPI transfer format, see section 18.4.4, Transfer Format. Note that the SSL0 output signal is not used for communication in clock synchronous operation.

### (2-2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after transmitting an RSPCK edge corresponding to the final sampling timing. If the SPRF bit in the RSPI status register (SPSR) is 0 and free space is available in the receive buffer, upon termination of serial transfer the RSPI copies data from the shift register to the receive buffer of the RSPI data register (SPDR).

It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the settings in bits SPB3 to SPB0 in SPCMD. For details on the RSPI transfer format, see section 18.4.4, Transfer Format. Note that the SSL0 output signal is not used for communication in clock synchronous operation.

### (2-3) Sequence Control

The transfer format that is employed in master mode is determined by the RSPI sequence control register (SPSCR), RSPI command registers 0 to 3 (SPCMD0 to SPCMD3), the RSPI bit rate register (SPBR), the RSPI clock delay register (SPCKD), the RSPI slave select negation delay register (SSLND), and the RSPI next-access delay register (SPND). Although no SSL signal is output in clock synchronous operation, these settings are valid.

The SPSCR register is used to determine the sequence configuration for serial transfers that are executed by a master mode RSPI. The following items are set in RSPI command registers SPCMD0 to SPCMD3: SSL output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.

According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMD0 to SPCMD3. The RSPI contains a pointer to the SPCMD that makes up the sequence. The value of this pointer can be checked by reading bits SPCP[1:0] in the RSPI sequence status register (SPSSR). When the SPE bit in the RSPI control register (SPCR) is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

**Figure 18.27 Determination Procedure of Serial Transfer Mode in Master Mode**

## (2-4) Initialization Flowchart

Figure 18.28 shows an example of initialization flowchart for using the RSPI in master mode during clock synchronous operation. For a description of how to set up an interrupt controller, the DTC/DMAC, and input/output ports, see the descriptions given in the individual blocks.

**Figure 18.28 Example of Initialization Flowchart in Master Mode**

## (2-5) Transfer Operation Flowchart

Figure 18.29 shows an example of transfer operation flowchart in master mode during clock synchronous operation.

**Figure 18.29 Example of Transfer Operation Flowchart in Master Mode**

### 18.4.11 Error Processing

Figures 18.30 and 18.31 show error processing. The RSPI can recover from an error which may occur in master or slave mode, using the following error processing.

**Figure 18.30 Error Processing (Overrun Error)**

**Figure 18.31 Error Processing (Mode Fault Error)**

### 18.4.12 Loopback Mode

When the CPU writes 1 to the SPLP bit in the RSPI pin control register (SPPCR), the RSPI shuts off the path between the MISO pin and the shift register, and between the MOSI pin and the shift register, and connects the input path and the output path (reversed) of the shift register. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the RSPI becomes the received data for the RSPI. Figure 18.32 shows the configuration of the shift register input/output paths for the case where the RSPI in master mode is set in loopback mode.

**Figure 18.32 Configuration of Shift Register Input/Output Paths in Loopback Mode (Master Mode)**

### 18.4.13 Interrupt Request

The interrupt sources for the RSPI include receive-buffer-full, transmission-buffer-empty, mode-fault, and overrun. With an interrupt request of receive-buffer-full or transmission-buffer-empty, the DTC or DMAC can start up and perform a data transfer.

The interrupt request of receive-buffer-full is allocated to the vector address of SPRI, the interrupt request of transmission-buffer-empty is allocated to the vector address of SPTI, and the interrupt requests of mode-fault and overrun are allocated to the vector address of SPEI. Therefore it is necessary to determine the interrupt source by the flag. Table 18.12 shows the interrupt sources for the RSPI.

When the interrupt condition is satisfied as shown in table 18.12, an interrupt occurs. Clear the interrupt source by executing a data transfer by the CPU or DTC/DMAC.

**Table 18.12 RSPI Interrupt Sources**

| <b>Name</b> | <b>Interrupt Source</b>   | <b>Symbol</b> | <b>Interrupt Condition</b> | <b>DTC/DMAC Startup</b> |
|-------------|---------------------------|---------------|----------------------------|-------------------------|
| SPRI        | Receive-buffer-full       | RXI           | (SPRIE=1) • (SPRF=1)       | Startup                 |
| SPTI        | Transmission-buffer-empty | TXI           | (SPTIE=1) • (SPTEF=1)      | Startup                 |
| SPEI        | Mode-fault                | MOI           | (SPEIE=1) • (MODF=1)       | —                       |
|             | Overrun                   | OVI           | (SPEIE=1) • (OVRF=1)       | —                       |

## 18.5 Usage Notes

### 18.5.1 DTC Block Transfer

To start a DTC block transfer due to RXI and TXI, set the block size in the DTC transfer count register (CRA) and the value in the block size counter to the same value as the number of frames set in the frame count setting bit. If these values are not the same, subsequent operations cannot be guaranteed.

### 18.5.2 DMAC Burst Transfer

To start a DMAC transfer due to RXI and TXI, set the value in the DMA transfer count register (DMATCR) to the same value as the number of frames set in the frame count setting bit. If these values are not the same, subsequent operations cannot be guaranteed.

### 18.5.3 Reading Receive Data

When reading the receive data by the CPU, clear the flag after the CPU reads the buffer for the specified number of times. If the flag is cleared before reaching the specified number of times, subsequent operations cannot be guaranteed.

### 18.5.4 DTC/DMAC and Mode Fault Error

If a mode fault error occurs when the SPTXI interrupt setting for DTC/DMAC is enabled while the SPTIE bit is valid, an unintended interrupt may occur. Clear the SPTIE bit while it is valid using the mode fault error processing (figure 18.31).

To use the DTC/DMAC after a mode fault error occurrence, reset the DTC/DMAC.

### 18.5.5 Usage of the RSPI Output Pins as Open Drain Outputs

When the RSPI output pins are to be used as open drain outputs, use a pull-up register to pull them up to the same electric potential as that on the  $V_{ccQ}$  pin.

Specify the pull-up resistance after enough evaluation to considerate whether the load satisfies the electrical characteristic requirements.

## Section 19 I<sup>2</sup>C Bus Interface 3 (IIC3)

The I<sup>2</sup>C bus interface 3 conforms to and provides a subset of the Philips I<sup>2</sup>C (Inter-IC) bus interface functions. However, the configuration of the registers that control the I<sup>2</sup>C bus differs partly from the Philips register configuration.

### 19.1 Features

- Selection of I<sup>2</sup>C format or clocked synchronous serial format
- Continuous transmission/reception

Since the shift register, transmit data register, and receive data register are independent from each other, the continuous transmission/reception can be performed.

#### I<sup>2</sup>C bus format:

- Start and stop conditions generated automatically in master mode
- Selection of acknowledge output levels when receiving
- Automatic loading of acknowledge bit when transmitting
- Bit synchronization/wait function

In master mode, the state of SCL is monitored per bit, and the timing is synchronized automatically. If transmission/reception is not yet possible, set the SCL to low until preparations are completed.

- Six interrupt sources

Transmit data empty (including slave-address match), transmit end, receive data full (including slave-address match), arbitration lost, NACK detection, and stop condition detection

- The direct memory access controller (DMAC) or data transfer controller (DTC) can be activated by a transmit-data-empty request or receive-data-full request to transfer data.
- Direct bus drive

Two pins, SCL and SDA pins, function as NMOS open-drain outputs when the bus drive function is selected.

#### Clocked synchronous serial format:

- Four interrupt sources

Transmit-data-empty, transmit-end, receive-data-full, and overrun error

- The direct memory access controller (DMAC) or data transfer controller (DTC) can be activated by a transmit-data-empty request or receive-data-full request to transfer data.

Figure 19.1 shows a block diagram of the I<sup>2</sup>C bus interface 3.

**Figure 19.1 Block Diagram of I<sup>2</sup>C Bus Interface 3**

## 19.2 Input/Output Pins

Table 19.1 shows the pin configuration of the I<sup>2</sup>C bus interface 3.

**Table 19.1 Pin Configuration**

| Pin Name     | Symbol | I/O | Function                                   |
|--------------|--------|-----|--------------------------------------------|
| Serial clock | SCL    | I/O | I <sup>2</sup> C serial clock input/output |
| Serial data  | SDA    | I/O | I <sup>2</sup> C serial data input/output  |

Figure 19.2 shows an example of I/O pin connections to external circuits.

**Figure 19.2 External Circuit Connections of I/O Pins**

## 19.3 Register Descriptions

The I<sup>2</sup>C bus interface 3 has the following registers.

**Table 19.2 Register Configuration**

| Register Name                                  | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------------------------------|--------------|-----|---------------|------------|-------------|
| I <sup>2</sup> C bus control register 1        | ICCR1        | R/W | H'00          | H'FFFEE000 | 8           |
| I <sup>2</sup> C bus control register 2        | ICCR2        | R/W | H'7D          | H'FFFEE001 | 8           |
| I <sup>2</sup> C bus mode register             | ICMR         | R/W | H'38          | H'FFFEE002 | 8           |
| I <sup>2</sup> C bus interrupt enable register | ICIER        | R/W | H'00          | H'FFFEE003 | 8           |
| I <sup>2</sup> C bus status register           | ICSR         | R/W | H'00          | H'FFFEE004 | 8           |
| Slave address register                         | SAR          | R/W | H'00          | H'FFFEE005 | 8           |
| I <sup>2</sup> C bus transmit data register    | ICDRT        | R/W | H'FF          | H'FFFEE006 | 8           |
| I <sup>2</sup> C bus receive data register     | ICDRR        | R/W | H'FF          | H'FFFEE007 | 8           |
| NF2CYC register                                | NF2CYC       | R/W | H'00          | H'FFFEE008 | 8           |

### 19.3.1 I<sup>2</sup>C Bus Control Register 1 (ICCR1)

ICCR1 is an 8-bit readable/writable register that enables or disables the I<sup>2</sup>C bus interface 3, controls transmission or reception, and selects master or slave mode, transmission or reception, and transfer clock frequency in master mode.

ICCR1 is initialized to H'00 by a power-on reset.

|                |     |      |     |     |          |     |     |     |
|----------------|-----|------|-----|-----|----------|-----|-----|-----|
| Bit:           | 7   | 6    | 5   | 4   | 3        | 2   | 1   | 0   |
|                | ICE | RCVD | MST | TRS | CKS[3:0] |     |     |     |
| Initial value: | 0   | 0    | 0   | 0   | 0        | 0   | 0   | 0   |

Note: The settings should satisfy external specifications.

### 19.3.2 I<sup>2</sup>C Bus Control Register 2 (ICCR2)

ICCR2 is an 8-bit readable/writable register that issues start/stop conditions, manipulates the SDA pin, monitors the SCL pin, and controls reset in the control part of the I<sup>2</sup>C bus.

ICCR2 is initialized to H'7D by a power-on reset.

### 19.3.3 I<sup>2</sup>C Bus Mode Register (ICMR)

ICMR is an 8-bit readable/writable register that selects whether the MSB or LSB is transferred first, and selects the transfer bit count.

ICMR is initialized to H'38 by a power-on reset. Bits BC[2:0] are initialized to H'0 by the IICRST bit in ICCR2.

| 2 to 0                      | BC[2:0]                           | 000           | R/W | <p>Bit Counter</p> <p>These bits specify the number of bits to be transferred next. When read, the remaining number of transfer bits is indicated. With the I<sup>2</sup>C bus format, the data is transferred with one addition acknowledge bit. Should be made between transfer frames. If these bits are set to a value other than B'000, the setting should be made while the SCL pin is low. After the stop condition is detected, the value of these bits returns automatically to B'111. The value returns to B'000 at the end of a data transfer, including the acknowledge bit. These bits are cleared by a power-on reset and in software standby mode and module standby mode. These bits are also cleared by setting the IICRST bit of ICCR2 to 1. With the clocked synchronous serial format, these bits should not be modified.</p> <table><tr><th>I<sup>2</sup>C Bus Format</th><th>Clocked Synchronous Serial Format</th></tr><tr><td>000: 9 bits</td><td>000: 8 bits</td></tr><tr><td>001: 2 bits</td><td>001: 1 bit</td></tr><tr><td>010: 3 bits</td><td>010: 2 bits</td></tr><tr><td>011: 4 bits</td><td>011: 3 bits</td></tr><tr><td>100: 5 bits</td><td>100: 4 bits</td></tr><tr><td>101: 6 bits</td><td>101: 5 bits</td></tr><tr><td>110: 7 bits</td><td>110: 6 bits</td></tr><tr><td>111: 8 bits</td><td>111: 7 bits</td></tr></table> | I <sup>2</sup> C Bus Format | Clocked Synchronous Serial Format | 000: 9 bits | 000: 8 bits | 001: 2 bits | 001: 1 bit | 010: 3 bits | 010: 2 bits | 011: 4 bits | 011: 3 bits | 100: 5 bits | 100: 4 bits | 101: 6 bits | 101: 5 bits | 110: 7 bits | 110: 6 bits | 111: 8 bits | 111: 7 bits |

### 19.3.4 I<sup>2</sup>C Bus Interrupt Enable Register (ICIER)

ICIER is an 8-bit readable/writable register that enables or disables interrupt sources and acknowledge bits, sets acknowledge bits to be transferred, and confirms acknowledge bits received.

ICIER is initialized to H'00 by a power-on reset.

### 19.3.5 I<sup>2</sup>C Bus Status Register (ICSR)

ICSR is an 8-bit readable/writable register that confirms interrupt request flags and their status.

ICSR is initialized to H'00 by a power-on reset.

### 19.3.6 Slave Address Register (SAR)

SAR is an 8-bit readable/writable register that selects the communications format and sets the slave address. In slave mode with the I<sup>2</sup>C bus format, if the upper seven bits of SAR match the upper seven bits of the first frame received after a start condition, this module operates as the slave device.

SAR is initialized to H'00 by a power-on reset.

### 19.3.7 I<sup>2</sup>C Bus Transmit Data Register (ICDRT)

ICDRT is an 8-bit readable/writable register that stores the transmit data. When ICDRT detects the space in the shift register (ICDRS), it transfers the transmit data which is written in ICDRT to ICDRS and starts transferring data. If the next transfer data is written to ICDRT during transferring data of ICDRS, continuous transfer is possible. ICDRT is initialized to H'FF.

|                |     |     |     |     |     |     |     |     |

### 19.3.8 I<sup>2</sup>C Bus Receive Data Register (ICDRR)

ICDRR is an 8-bit register that stores the receive data. When data of one byte is received, ICDRR transfers the receive data from ICDRS to ICDRR and the next data can be received. ICDRR is a receive-only register, therefore the CPU cannot write to this register.

ICDRR is initialized to H'FF by a power-on reset.

### 19.3.9 I<sup>2</sup>C Bus Shift Register (ICDRS)

ICDRS is a register that is used to transfer/receive data. In transmission, data is transferred from ICDRT to ICDRS and the data is sent from the SDA pin. In reception, data is transferred from ICDRS to ICDRR after data of one byte is received. This register cannot be read directly from the CPU.

|                |                          |                          |                          |                          |                          |                          |                          |                          |
|----------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|--------------------------|
| Bit:           | 7                        | 6                        | 5                        | 4                        | 3                        | 2                        | 1                        | 0                        |

### 19.3.10 NF2CYC Register (NF2CYC)

NF2CYC is an 8-bit readable/writable register that selects the range of the noise filtering for the SCL and SDA pins. For details of the noise filter, see section 19.4.7, Noise Filter.

NF2CYC is initialized to H'00 by a power-on reset.

## 19.4 Operation

The I<sup>2</sup>C bus interface 3 can communicate either in I<sup>2</sup>C bus mode or clocked synchronous serial mode by setting FS in SAR.

### 19.4.1 I<sup>2</sup>C Bus Format

Figure 19.3 shows the I<sup>2</sup>C bus formats. Figure 19.4 shows the I<sup>2</sup>C bus timing. The first frame following a start condition always consists of eight bits.

**Figure 19.3 I<sup>2</sup>C Bus Formats**

**Figure 19.4 I<sup>2</sup>C Bus Timing**

#### [Legend]

S: Start condition. The master device drives SDA from high to low while SCL is high.

SLA: Slave address

R/W: Indicates the direction of data transfer: from the slave device to the master device when R/W is 1, or from the master device to the slave device when R/W is 0.

A: Acknowledge. The receive device drives SDA to low.

DATA: Transfer data

P: Stop condition. The master device drives SDA from low to high while SCL is high.

### 19.4.2 Master Transmit Operation

In master transmit mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For master transmit mode operation timing, refer to figures 19.5 and 19.6. The transmission procedure and operations in master transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Also, set ICMR and bits CKS[3:0] in ICCR1. (Initial setting)
2. Read the BBSY flag in ICCR2 to confirm that the bus is released. Set the MST and TRS bits in ICCR1 to select master transmit mode. Then, write 1 to BBSY and 0 to SCP. (Start condition issued) This generates the start condition.
3. After confirming that TDRE in ICSR has been set, write the transmit data (the first byte data show the slave address and R/W) to ICDRT. At this time, TDRE is automatically cleared to 0, and data is transferred from ICDRT to ICDRS. TDRE is set again.
4. When transmission of one byte data is completed while TDRE is 1, TEND in ICSR is set to 1 at the rise of the 9th transmit clock pulse. Read the ACKBR bit in ICIER, and confirm that the slave device has been selected. Then, write second byte data to ICDRT. When ACKBR is 1, the slave device has not been acknowledged, so issue the stop condition. To issue the stop condition, write 0 to BBSY and SCP. SCL is fixed low until the transmit data is prepared or the stop condition is issued.
5. The transmit data after the second byte is written to ICDRT every time TDRE is set.
6. Write the number of bytes to be transmitted to ICDRT. Wait until TEND is set (the end of last byte data transmission) while TDRE is 1, or wait for NACK (NACKF in ICSR = 1) from the receive device while ACKF in ICIER is 1. Then, issue the stop condition to clear TEND or NACKF.
7. When the STOP bit in ICSR is set to 1, the operation returns to slave receive mode.

**Figure 19.5 Master Transmit Mode Operation Timing (1)**

**Figure 19.6 Master Transmit Mode Operation Timing (2)**

### 19.4.3 Master Receive Operation

In master receive mode, the master device outputs the receive clock, receives data from the slave device, and returns an acknowledge signal. For master receive mode operation timing, refer to figures 19.7 and 19.8. The reception procedure and operations in master receive mode are shown below.

1. Clear the TEND bit in ICSR to 0, then clear the TRS bit in ICCR1 to 0 to switch from master transmit mode to master receive mode. Then, clear the TDRE bit to 0.
2. When ICDRR is read (dummy data read), reception is started, and the receive clock is output, and data received, in synchronization with the internal clock. The master device outputs the level specified by ACKBT in ICIER to SDA, at the 9th receive clock pulse.
3. After the reception of first frame data is completed, the RDRF bit in ICSR is set to 1 at the rise of 9th receive clock pulse. At this time, the receive data is read by reading ICDRR, and RDRF is cleared to 0.
4. The continuous reception is performed by reading ICDRR every time RDRF is set. If 8th receive clock pulse falls after reading ICDRR by the other processing while RDRF is 1, SCL is fixed low until ICDRR is read.
5. If next frame is the last receive data, set the RCVD bit in ICCR1 to 1 before reading ICDRR. This enables the issuance of the stop condition after the next reception.
6. When the RDRF bit is set to 1 at rise of the 9th receive clock pulse, issue the stage condition.
7. When the STOP bit in ICSR is set to 1, read ICDRR. Then clear the RCVD bit to 0.
8. The operation returns to slave receive mode.

Note: If only one byte is received, read ICDRR (dummy-read) after the RCVD bit in ICCR1 is set.

Figure 19.7 Master Receive Mode Operation Timing (1)

Figure 19.8 Master Receive Mode Operation Timing (2)

### 19.4.4 Slave Transmit Operation

In slave transmit mode, the slave device outputs the transmit data, while the master device outputs the receive clock and returns an acknowledge signal. For slave transmit mode operation timing, refer to figures 19.9 and 19.10.

The transmission procedure and operations in slave transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At this time, if the 8th bit data ( $\overline{R/W}$ ) is 1, the TRS bit in ICCR1 and the TDRE bit in ICSR are set to 1, and the mode changes to slave transmit mode automatically. The continuous transmission is performed by writing transmit data to ICDRT every time TDRE is set.
3. If TDRE is set after writing last transmit data to ICDRT, wait until TEND in ICSR is set to 1, with TDRE = 1. When TEND is set, clear TEND.
4. Clear TRS for the end processing, and read ICDRR (dummy read). SCL is opened.
5. Clear TDRE.

**Figure 19.9 Slave Transmit Mode Operation Timing (1)**

**Figure 19.10 Slave Transmit Mode Operation Timing (2)**

### 19.4.5 Slave Receive Operation

In slave receive mode, the master device outputs the transmit clock and transmit data, and the slave device returns an acknowledge signal. For slave receive mode operation timing, refer to figures 19.11 and 19.12. The reception procedure and operations in slave receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting) Set the MST and TRS bits in ICCR1 to select slave receive mode, and wait until the slave address matches.
2. When the slave address matches in the first frame following detection of the start condition, the slave device outputs the level specified by ACKBT in ICIER to SDA, at the rise of the 9th clock pulse. At the same time, RDRF in ICSR is set to read ICDRR (dummy read). (Since the read data show the slave address and  $R/\overline{W}$ , it is not used.)
3. Read ICDRR every time RDRF is set. If 8th receive clock pulse falls while RDRF is 1, SCL is fixed low until ICDRR is read. The change of the acknowledge before reading ICDRR, to be returned to the master device, is reflected to the next transmit frame.
4. The last byte data is read by reading ICDRR.

**Figure 19.11 Slave Receive Mode Operation Timing (1)**

**Figure 19.12 Slave Receive Mode Operation Timing (2)**

### 19.4.6 Clocked Synchronous Serial Format

This module can be operated with the clocked synchronous serial format, by setting the FS bit in SAR to 1. When the MST bit in ICCR1 is 1, the transfer clock output from SCL is selected. When MST is 0, the external clock input is selected.

#### (1) Data Transfer Format

Figure 19.13 shows the clocked synchronous serial transfer format.

The transfer data is output from the fall to the fall of the SCL clock, and the data at the rising edge of the SCL clock is guaranteed. The MLS bit in ICMR sets the order of data transfer, in either the MSB first or LSB first. The output level of SDA can be changed during the transfer wait, by the SDAO bit in ICCR2.

**Figure 19.13 Clocked Synchronous Serial Transfer Format**

#### (2) Transmit Operation

In transmit mode, transmit data is output from SDA, in synchronization with the fall of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For transmit mode operation timing, refer to figure 19.14. The transmission procedure and operations in transmit mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set the MST and CKS[3:0] bits in ICCR1. (Initial setting)
2. Set the TRS bit in ICCR1 to select transmit mode. Then, TDRE in ICSR is set.
3. Confirm that TDRE has been set. Then, write the transmit data to ICDRT. The data is transferred from ICDRT to ICDRS, and TDRE is set automatically. The continuous transmission is performed by writing data to ICDRT every time TDRE is set. When changing from transmit mode to receive mode, clear TRS while TDRE is 1.

**Figure 19.14 Transmit Mode Operation Timing**

### (3) Receive Operation

In receive mode, data is latched at the rise of the transfer clock. The transfer clock is output when MST in ICCR1 is 1, and is input when MST is 0. For receive mode operation timing, refer to figure 19.15. The reception procedure and operations in receive mode are described below.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting)
2. When the transfer clock is output, set MST to 1 to start outputting the receive clock.
3. When the receive operation is completed, data is transferred from ICDRS to ICDRR and RDRF in ICSR is set. When MST = 1, the next byte can be received, so the clock is continually output. The continuous reception is performed by reading ICDRR every time RDRF is set. When the 8th clock rises while RDRF is 1, the overrun is detected and AL/OVE in ICSR is set. At this time, the previous reception data is retained in ICDRR.
4. To stop receiving when MST = 1, set RCVD in ICCR1 to 1, then read ICDRR. Then, SCL is fixed high after receiving the next byte data.

Notes: Follow the steps below to receive only one byte with MST = 1 specified. See figure 19.16 for the operation timing.

1. Set the ICE bit in ICCR1 to 1. Set bits CKS[3:0] in ICCR1. (Initial setting)
2. Set MST = 1 while the RCVD bit in ICCR1 is 0. This causes the receive clock to be output.
3. Check if the BC2 bit in ICMR is set to 1 and then set the RCVD bit in ICCR1 to 1. This causes the SCL to be fixed to the high level after outputting one byte of the receive clock.

**Figure 19.15 Receive Mode Operation Timing**

**Figure 19.16 Operation Timing For Receiving One Byte (MST = 1)**

### 19.4.7 Noise Filter

The logic levels at the SCL and SDA pins are routed through noise filters before being latched internally. Figure 19.17 shows a block diagram of the noise filter circuit.

The noise filter consists of three cascaded latches and a match detector. The SCL (or SDA) input signal is sampled on the peripheral clock. When NF2CYC is set to 0, this signal is not passed forward to the next circuit unless the outputs of both latches agree. When NF2CYC is set to 1, this signal is not passed forward to the next circuit unless the outputs of three latches agree. If they do not agree, the previous value is held.

**Figure 19.17 Block Diagram of Noise Filter**

### 19.4.8 Using the IICRST Bit to Reset I<sup>2</sup>C Bus Interface 3

Some registers and the control part for I<sup>2</sup>C of the I<sup>2</sup>C bus interface 3 can be reset by writing 1 to the IICRST bit in ICCR2. Figure 19.18 shows an example of the sequence for resetting the I<sup>2</sup>C bus interface 3 by using the IICRST bit.

**Figure 19.18 Sequence for Using the IICRST Bit to Reset I<sup>2</sup>C Bus Interface 3**

### 19.4.9 Example of Use

Flowcharts in respective modes that use the I<sup>2</sup>C bus interface 3 are shown in figures 19.19 to 19.22.

**Figure 19.19 Sample Flowchart for Master Transmit Mode**

**Figure 19.20 Sample Flowchart for Master Receive Mode**

**Figure 19.21 Sample Flowchart for Slave Transmit Mode**

**Figure 19.22 Sample Flowchart for Slave Receive Mode**

## 19.5 Interrupt Requests

There are six interrupt requests in this module; transmit data empty, transmit end, receive data full, NACK detection, STOP recognition, and arbitration lost/overrun error. Table 19.4 shows the contents of each interrupt request.

**Table 19.4 Interrupt Requests**

| Interrupt Request                  | Abbreviation | Interrupt Condition        | I <sup>2</sup> C Bus Format | Clocked Synchronous Serial Format |
|------------------------------------|--------------|----------------------------|-----------------------------|-----------------------------------|
| Transmit data Empty                | TXI          | (TDRE = 1) • (TIE = 1)     | √                           | √                                 |
| Transmit end                       | TEI          | (TEND = 1) • (TEIE = 1)    | √                           | √                                 |
| Receive data full                  | RXI          | (RDRF = 1) • (RIE = 1)     | √                           | √                                 |
| STOP recognition                   | STPI         | (STOP = 1) • (STIE = 1)    | √                           | —                                 |
| NACK detection                     | NAKI         | {(NACKF = 1) + (AL = 1)} • | √                           | —                                 |
| Arbitration lost/<br>overrun error |              | (NAKIE = 1)                | √                           | √                                 |

When the interrupt condition described in table 19.4 is 1, the CPU executes an interrupt exception handling. Note that a TXI or RXI interrupt can activate the DMAC or DTC if the setting for DMAC or DTC activation has been made. In such a case, an interrupt request is not sent to the CPU. Interrupt sources should be cleared in the exception handling. The TDRE and TEND bits are automatically cleared to 0 by writing the transmit data to ICDRT. The RDRF bit is automatically cleared to 0 by reading ICDRR. The TDRE bit is set to 1 again at the same time when the transmit data is written to ICDRT. Therefore, when the TDRE bit is cleared to 0, then an excessive data of one byte may be transmitted.

## 19.6 Data Transfer Using DTC

In the I<sup>2</sup>C bus format, the slave device and transfer direction are selected through the slave address and R/W bit, and data reception is confirmed and the last frame is indicated through the acknowledge bit. Therefore, when the DTC is used to transfer data continuously, the DTC processing should be done in combination with the CPU processing activated by interrupts.

Table 19.5 shows an example of I<sup>2</sup>C data transfer using the DTC. This example assumes that the transfer data count is determined in advance in slave mode.

**Table 19.5 Example of Data Transfer Using DTC**

| Item                                     | Master Transmit Mode                                                                             | Master Receive Mode               | Slave Transmit Mode               | Slave Receive Mode             |

## 19.7 Bit Synchronous Circuit

In master mode, this module has a possibility that high level period may be short in the two states described below.

- When SCL is driven to low by the slave device
- When the rising speed of SCL is lowered by the load of the SCL line (load capacitance or pull-up resistance)

Therefore, it monitors SCL and communicates by bit with synchronization.

Figure 19.23 shows the timing of the bit synchronous circuit and table 19.6 shows the time when the SCL output changes from low to Hi-Z then SCL is monitored.

(a) SCL is normally driven

(b) When SCL is driven to low by the slave device

(c) When the rising speed of SCL is lowered

- Notes: 1. The clock is the transfer rate clock set by the CKS[3:0] bit in I2C Bus Control Register 1 (ICCR1).  
 2. When the NF2CYC bit in NF2CYC Register (NF2CYC) is set to 0, the internal delay time is 3 to 4 tpcyc. When this bit is set to 1, the internal delay time is 4 to 5 tpcyc.

**Figure 19.23 Bit Synchronous Circuit Timing**

**Table 19.6 Time for Monitoring SCL**

| CKS[3] | CKS[2] | Time for Monitoring SCL |
|--------|--------|-------------------------|
| 0      | 0      | 9 tpcyc*                |
|        | 1      | 21 tpcyc*               |
| 1      | 0      | 39 tpcyc*               |
|        | 1      | 87 tpcyc*               |

Note: \* tpcyc indicates peripheral clock (P $\phi$ ) cycle.

## 19.8 Usage Notes

### 19.8.1 Setting for Multi-Master Operation

In multi-master operation, when the setting for IIC transfer rate (ICCR1.CKS[3:0]) makes this LSI slower than the other masters, pulse cycles with an unexpected length will infrequently be output on SCL.

Be sure to specify a transfer rate that is at least 1/1.8 of the fastest transfer rate among the other masters.

### 19.8.2 Note on Master Receive Mode

Reading ICDRR around the falling edge of the 8th clock might fail to fetch the receive data.

In addition, when RCVD is set to 1 around the falling edge of the 8th clock and the receive buffer is full, a stop condition may not be issued.

Use either of the following measures 1 or 2 against the situations above.

1. In master receive mode, read ICDRR before the rising edge of the 8th clock.
2. In master receive mode, set RCVD to 1 so that data is received in byte units.

### 19.8.3 Note on Setting ACKBT in Master Receive Mode

In master receive mode operation, set ACKBT before the falling edge of the 8th SCL cycle of the last data being continuously transferred. Not doing so can lead to an overrun for the slave transmission device.

### 19.8.4 Note on the States of Bits MST and TRN when Arbitration Is Lost

When sequential bit-manipulation instructions are used to set the MST and TRS bits to select master transmission in multi-master operation, a conflicting situation where AL in ICSR = 1 but the mode is master transmit mode (MST = 1 and TRS = 1) may arise; this depends on the timing of the loss of arbitration when the bit manipulation instruction for TRS is executed.

This can be avoided in either of the following ways.

- In multi-master operation, use the MOV instruction to set the MST and TRS bits.
- When arbitration is lost, check whether the MST and TRS bits are 0. If the MST and TRS bits have been set to a value other than 0, clear the bits to 0.

### 19.8.5 Access to ICE and IICRST Bits during I<sup>2</sup>C Bus Operations

Writing 0 to the ICE bit in ICCR1 or 1 to the IICRST bit in ICCR2 while this LSI is in any of the following states (1 to 4) causes the BBSY flag in ICCR2 and the STOP flag in ICSR to become undefined.

1. This module is the I<sup>2</sup>C bus master in master transmit mode (MST = 1 and TRS = 1 in ICCR1).
2. This module is the I<sup>2</sup>C bus master in master receive mode (MST = 1 and TRS = 0 in ICCR1).
3. This module is transmitting data in slave transmit mode (MST = 0 and TRS = 1 in ICCR1).
4. This module is transmitting acknowledge signals in slave receive mode (MST = 0 and TRS = 0 in ICCR1).

Executing any of the following procedures releases the BBSY flag in ICCR2 from the undefined state.

- Input a start condition (falling edge of SDA while SCL is at the high level) to set the BBSY flag to 1.
- Input a stop condition (rising edge of SDA while SCL is at the high level) to clear the BBSY flag to 0.
- If the module is in master transmit mode, issue a start condition by writing 1 and 0 to the BBSY flag and the SCP bit in ICCR2, respectively, while SCL and SDA are at the high level. The BBSY flag is set to 1 on output of the start condition (falling edge of SDA while SCL is at the high level).

- With the module in master transmit or master receive mode, SDA at the low level, and no other device holding SCL at the low level, issue a stop condition by writing 0 to the BBSY flag and the SCP bit in ICCR2. The BBSY flag is cleared to 0 on output of the stop condition (rising edge of SDA while SCL is at the high level).
- Writing 1 to the FS bit in SAR clears the BBST flag to 0.

### 19.8.6 Using the IICRST Bit to Initialize the Registers

- Writing 1 to the IICRST bit sets the SDAO and SCLO bits in ICCR2 to 1.
- Writing 1 to the IICRST bit in master transmit mode or slave transmit mode sets the TDRE flag in ICSR to 1.
- During a reset due to the IICRST bit being set to 1, writing to the BBSY flag and the SCP and SDAO bits is invalid.
- Even during a reset due to the IICRST bit being set to 1, the input of a start (falling edge of SDA while SCL is at the high level) or stop (rising edge of SDA while SCL is at the high level) condition on SCL and SDA causes the BBSY flag to be set to 1 or cleared to 0, respectively.

### 19.8.7 Operation of I<sup>2</sup>C Bus Interface 3 while ICE = 0

Writing 0 to the ICE bit in ICCR1 disables output on SCL and SDA. However, input on SCL and SDA remains valid. This module operates in accord with the signals input on SCL and SDA.

### 19.8.8 Note on Master Transmit Mode

When the ACKE bit is set to 1 in master transmit mode, issue a stop condition after confirming the falling edge of the 9th clock of SCL.

## Section 20 A/D Converter (ADC)

This LSI includes a successive approximation type 12-bit A/D converter.

### 20.1 Features

- 12-bit resolution
- Input channels: Eight channels
- High-speed conversion

When  $A\phi = 50$  MHz: Minimum 1.0  $\mu$ s per channel

AD clock = 50 MHz, 50 conversion states

- Two operating modes
  - Single-cycle scan mode: Continuous A/D conversion on one to four channels
  - Continuous scan mode: Repetitive A/D conversion on one to four channels
- Eight A/D data registers

A/D conversion results are stored in 16-bit A/D data registers (ADDR) that correspond to the input channels.
- Sample-and-hold function

Sample-and-hold circuits are built into the A/D converter of this LSI, simplifying the configuration of the external analog input circuitry. Multiple channels can be sampled simultaneously because sample-and-hold circuits can be dedicated to channels 0 to 2.

  - Group A (GrA): Analog input pins selected from channels 0, 1, and 2 can be simultaneously sampled.
- Three methods for starting A/D conversion

Software: Setting of the ADST bit in ADCR

Timer: TRGAN, TRG0N, TRG4AN, and TRG4BN from the MTU2

TRGAN, TRG4AN, and TRG4BN from the MTU2S

External trigger:  $\overline{ADTRG}$  (LSI pin)
- Selectable analog input channel

A/D conversion of a selected channel is accomplished by setting the A/D analog input channel select registers (ADANSR).
- A/D conversion end interrupt, DMAC transfer function, and DTC transfer function are supported

On completion of A/D conversion, A/D conversion end interrupts (ADI) can be generated and the DMAC or DTC can be activated by an ADI.

Figure 20.1 shows a block diagram of the A/D converter.

**Figure 20.1 Block Diagram of A/D Converter**

## 20.2 Input/Output Pins

Table 20.1 shows the configuration of the pins used by the A/D converter. For the pin usage, refer to the usage notes in section 20.7, Usage Notes.

**Table 20.1 Pin Configuration**

| Module                  | Pin Name         | I/O   | Function                                       |
|-------------------------|------------------|-------|------------------------------------------------|
| Common                  | AV <sub>cc</sub> | Input | Analog block power supply pin                  |
|                         | AV <sub>ss</sub> | Input | Analog block ground pin                        |
|                         | AVREF            | Input | Analog block reference power supply pin (high) |
|                         | AVREFVSS         | Input | Analog block reference power supply pin (low)  |
|                         | ADTRG            | Input | A/D external trigger input pin                 |
| A/D module 0<br>(A/D_0) | AN0              | Input | Analog input pin 0 (Group A)                   |
|                         | AN1              | Input | Analog input pin 1 (Group A)                   |
|                         | AN2              | Input | Analog input pin 2 (Group A)                   |
|                         | AN3              | Input | Analog input pin 3                             |
| A/D module 1<br>(A/D_1) | AN4              | Input | Analog input pin 4                             |
|                         | AN5              | Input | Analog input pin 5                             |
|                         | AN6              | Input | Analog input pin 6                             |
|                         | AN7              | Input | Analog input pin 7                             |

## 20.3 Register Descriptions

The A/D converter has the following registers.

**Table 20.2 Register Configuration**

| Register Name                              | Abbreviation | R/W | Initial Value | Address    | Access Size |
|--------------------------------------------|--------------|-----|---------------|------------|-------------|
| A/D control register_0                     | ADCR_0       | R/W | H'00          | H'FFFFE800 | 8           |
| A/D status register_0                      | ADSR_0       | R/W | H'00          | H'FFFFE802 | 8           |
| A/D start trigger select register_0        | ADSTRGR_0    | R/W | H'00          | H'FFFFE81C | 8           |
| A/D analog input channel select register_0 | ADANSR_0     | R/W | H'00          | H'FFFFE820 | 8           |
| A/D bypass control register_0              | ADBYPSCR_0   | R/W | H'00          | H'FFFFE830 | 8           |
| A/D data register 0                        | ADDR0        | R   | H'0000        | H'FFFFE840 | 16          |
| A/D data register 1                        | ADDR1        | R   | H'0000        | H'FFFFE842 | 16          |
| A/D data register 2                        | ADDR2        | R   | H'0000        | H'FFFFE844 | 16          |
| A/D data register 3                        | ADDR3        | R   | H'0000        | H'FFFFE846 | 16          |
| A/D control register_1                     | ADCR_1       | R/W | H'00          | H'FFFFEC00 | 8           |
| A/D status register_1                      | ADSR_1       | R/W | H'00          | H'FFFFEC02 | 8           |
| A/D start trigger select register_1        | ADSTRGR_1    | R/W | H'00          | H'FFFFEC1C | 8           |
| A/D analog input channel select register_1 | ADANSR_1     | R/W | H'00          | H'FFFFEC20 | 8           |
| A/D bypass control register_1              | ADBYPSCR_1   | R/W | H'00          | H'FFFFEC30 | 8           |
| A/D data register 4                        | ADDR4        | R   | H'0000        | H'FFFFEC40 | 16          |
| A/D data register 5                        | ADDR5        | R   | H'0000        | H'FFFFEC42 | 16          |
| A/D data register 6                        | ADDR6        | R   | H'0000        | H'FFFFEC44 | 16          |
| A/D data register 7                        | ADDR7        | R   | H'0000        | H'FFFFEC46 | 16          |

### 20.3.1 A/D Control Registers 0 and 1 (ADCR\_0 and ADCR\_1)

ADCR is an 8-bit readable/writable register that selects A/D conversion mode and others.

|                |       |       |       |       |   |   |       |       |
|----------------|-------|-------|-------|-------|---|---|-------|-------|
| Bit:           | 7     | 6     | 5     | 4     | 3 | 2 | 1     | 0     |
|                | ADST  | ADCS  | ACE   | ADIE  | - | - | TRGE  | EXTRG |
| Initial value: | 0     | 0     | 0     | 0     | 0 | 0 | 0     | 0     |
| R/W:           | R/W*1 | R/W*2 | R/W*2 | R/W*2 | R | R | R/W*2 | R/W*2 |

- Notes:
1. Do not overwrite 1 while the ADST bit is set to 1.
  2. Do not modify the value of this bit while the ADST bit is set to 1.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | ADST     | 0             | R/W | <p><b>A/D Start</b></p> <p>When this bit is cleared to 0, A/D conversion is stopped and the A/D converter enters the idle state. When this bit is set to 1, A/D conversion is started. In single-cycle scan mode, this bit is automatically cleared to 0 when A/D conversion ends on the selected single channel. In continuous scan mode, A/D conversion is continuously performed for the selected channels in sequence until this bit is cleared by software, a reset, or in software standby mode.</p> <p>Note: Setting of the ADST bit must be done while it is cleared to 0 to prevent incorrect operations.</p> |
| 6   | ADCS     | 0             | R/W | <p><b>A/D Continuous Scan</b></p> <p>Selects either a single-cycle or a continuous scan in scan mode. This bit is valid only when scan mode is selected.</p> <p>0: Single-cycle scan<br/>1: Continuous scan</p> <p>When changing the operating mode, first clear the ADST bit to 0.</p>                                                                                                                                                                                                                                                                                                                                |

| Bit  | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The operation which is performed when 1 is written to the ADST bit by software is subsequently performed. A/D conversion start by the external trigger input is enabled only when the ADST bit is cleared to 0.</p> <p>When the external trigger is used as an A/D conversion start trigger, the low-level pulse input to the <math>\overline{\text{ADTRG}}</math> pin must be at least 1.5 P<math>\phi</math> clock cycles in width.</p> <p>0: A/D converter is started by the A/D conversion start trigger from the MTU2 or MTU2S</p> <p>1: A/D converter is started by the external pin (<math>\overline{\text{ADTRG}}</math>)</p> |

### 20.3.2 A/D Status Registers 0 to 1 (ADSR\_0 and ADSR\_1)

ADSR is an 8-bit readable/writable register that indicates the status of the A/D converter.

|                |   |   |   |   |   |   |   |        |

### 20.3.3 A/D Start Trigger Select Registers 0 and 1 (ADSTRGR\_0 and ADSTRGR\_1)

ADSTRGR selects an A/D conversion start trigger from the MTU2 or MTU2S. The A/D conversion start trigger is used as an A/D conversion start source when the TRGE bit in ADCR is set to 1 and the EXTRG bit in ADCR is set to 0.

### 20.3.4 A/D Analog Input Channel Select Registers 0 and 1 (ADANSR\_0 and ADANSR\_1)

ADANSR is an 8-bit readable/writable register that selects an analog input channel.

### 20.3.5 A/D Bypass Control Registers 0 and 1 (ADBYPSCR\_0 and ADBYPSCR\_1)

For A/D conversion of group A (GrA), it can be selected whether or not to use the sample-and-hold circuits dedicated to the group A channels.

Setting the SH bit in ADBYPSCR\_0 to 1 selects the sample-and-hold circuits dedicated to the channels. When the sample-and-hold circuits are not to be used, the A/D conversion time does not include the time for sampling in the dedicated sample-and-hold circuits. For details, refer to section 20.4, Operation.

The function of the SH bit in this register is available only for A/D converter\_0. A/D converter\_1 is always in the same state as when the SH bit is set to 0.

### 20.3.6 A/D Data Registers 0 to 7 (ADDR0 to ADDR7)

ADDRs are 16-bit read-only registers. The conversion result for each analog input channel is stored in ADDR with the corresponding number. (See table 20.4.)

The converted 12-bit data is stored in bits 11 to 0.

The initial value of ADDR is H'0000.

After ADDR is read, ADDR can be automatically cleared to H'0000 by setting the ACE bit in ADCR to 1.

## 20.4 Operation

The A/D converter has two operating modes: single-cycle scan mode and continuous scan mode. In single-cycle scan mode, A/D conversion is performed once on one or more specified channels and then it ends. In continuous scan mode, the A/D conversion is performed sequentially on one or more specified channels until the ADST bit is cleared to 0.

The ADCS bit in the A/D control register (ADCR) is used to select the operating mode. Setting the ADCS bit to 0 selects single-cycle scan mode and setting the ADCS bit to 1 selects continuous scan mode. In both modes, A/D conversion starts on the channel with the lowest number in the analog input channels selected by the A/D analog input channel select register (ADANSR) from AN0 to AN3.

In single-cycle scan mode, when one cycle of A/D conversion on all specified channels is completed, the ADF bit in ADSR is set to 1 and the ADST bit is automatically cleared to 0. In continuous scan mode, when conversion on all specified channels is completed, the ADF bit in ADSR is set to 1. To stop A/D conversion, write 0 to the ADST bit. When the ADF bit is set to 1, if the ADIE bit in ADCR is set to 1, an A/D conversion end interrupt (ADI) is generated. When clearing the ADF bit to 0, read the ADF bit while set to 1 and then write 0. However, when the DMAC or DTC is activated by an ADI interrupt, the ADF bit is automatically cleared to 0.

### 20.4.1 Single-Cycle Scan Mode

The following example shows the operation when analog input channels 0 to 3 (AN0 to AN3) are selected and the A/D conversion is performed in single-cycle scan mode using four channels.

1. Set the ADCS bit in the A/D control register (ADCR) to 0.
2. Set all bits ANS0 to ANS3 in the A/D analog input channel select register (ADANSR) to 1.
3. Set the SH bit in the A/D bypass control register\_0 (ADBYPSCR\_0).
4. Set the ADST bit in the A/D control register (ADCR) to 1 to start A/D conversion.
5. Channels 0 to 2 (GrA) are sampled simultaneously\*. Then, A/D conversion is performed on channel 0. Upon completion of the A/D conversion, the A/D conversion result is transferred to ADDR0. In the same way, channels 1 and 2 are converted and the A/D conversion results are transferred to ADDR1 and ADDR2.
6. A/D conversion of channel 3 is then started. Upon completion of the A/D conversion, the A/D conversion result is transferred to ADDR3.

7. When A/D conversion ends on all specified channels (AN0 to AN3), the ADF bit is set to 1, the ADST bit is automatically cleared to 0, and the A/D conversion ends. At this time, if the ADIE bit is set to 1, an ADI interrupt is generated after the A/D conversion.

Note: \* The operation depends on the SH bit setting in ADBYPSCR\_0. For details, see figures 20.2 and 20.3.

**Figure 20.2 Example 1 of A/D\_0 Converter Operation (Single-Cycle Scan Mode and Sample-and-Hold Circuit Enabled)**

**Figure 20.3 Example 2 of A/D\_0 Converter Operation (Single-Cycle Scan Mode and Sample-and-Hold Circuit Disabled)**

### 20.4.2 Continuous Scan Mode

The following example shows the operation when analog input 0, 2, and 3 (AN0, AN2, AN3) are selected and the A/D conversion is performed in continuous scan mode using the three channels. This operation also applies to the A/D<sub>1</sub> conversion.

1. Set the ADCS bit in the A/D control register (ADCR) to 0.
2. Set all bits of ANS0, ANS2, and ANS3 in the A/D analog input channel select register (ADANSR) to 1.
3. Set the SH bit in the A/D bypass control register<sub>0</sub> (ADBYPSCR<sub>0</sub>).
4. Set the ADST bit in the A/D control register (ADCR) to 1 to start A/D conversion.
5. Channels 0 and 2 (GrA) are sampled simultaneously\*. As the ANS1 bit in ADANSR is set to 0, channel 1 is not sampled. Then the A/D conversion on channel 0 is started. Upon completion of the A/D conversion, the A/D conversion result is transferred to ADDR0. In the same way, channel 2 is converted and the A/D conversion result is transferred to ADDR2. The A/D conversion is not performed on channel 1.
6. The A/D conversion of channel 3 starts. Upon completion of the A/D conversion, the A/D conversion result is transferred to ADDR3.
7. When the A/D conversion ends on all the specified channels (AN0, AN2, and AN3), the ADF bit is set to 1. At this time, if the ADIE bit is set to 1, an ADI interrupt is generated after the A/D conversion.
8. Steps 5 to 7 are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, the A/D conversion stops. After this, if the ADST bit is set to 1, the A/D conversion starts again and repeats steps 5 to 7.

Note: \* The operation depends on the SH bit setting in ADBYPSCR<sub>0</sub>. For details, see figures 20.4 and 20.5.

**Figure 20.4 Example 1 of A/D\_0 Converter Operation (Continuous Scan Mode and Sample-and-Hold Circuit Enabled)**

**Figure 20.5 Example 2 of A/D\_0 Converter Operation (Continuous Scan Mode and Sample-and-Hold Circuit Disabled)**

### 20.4.3 Input Sampling and A/D Conversion Time

The A/D converter has built-in sample-and-hold circuits. Channels 0 to 2 can be simultaneously sampled as one group when the SH bit in ADBYPSCR\_0 is set to 1. This group is referred to as Group A (GrA) (in table 20.5). When the SH bit is cleared to 0, these channels are sampled individually in the same way as other channels.

Setting the ADST bit to 1 starts A/D conversion. The A/D conversion time ( $t_{\text{CONV}}$ ) from the beginning to the end of conversion is determined by the following four time factors (figure 20.6): the A/D conversion start delay time ( $t_d$ ), sampling time ( $t_{\text{SPLSH}}$ ), sampling time ( $t_{\text{SPL}}$ ), and A/D conversion processing time; the A/D conversion time ( $t_{\text{CONV}}$ ) is the sum of these times.  $t_{\text{SPLSH}}$  can be reduced according to the following procedure.

To reduce  $t_{\text{SPLSH}}$ , clear the SH bit in ADBYPSCR\_0 to 0 (initial value). Note that when GrA channels should be sampled simultaneously, the SH bit should be set to 1 to provide appropriate  $t_{\text{SPLSH}}$ .  $t_{\text{SPLSH}}$  indicates the time required for the operation of the sample-and-hold circuits dedicated to channels 0 to 2 and it does not depend on the number of channels sampled simultaneously.

In continuous scan mode, the A/D conversion time ( $t_{\text{CONV}}$ ) given in table 20.6 applies to the conversion time of the first cycle. The conversion time of the second and subsequent cycles is expressed as ( $t_{\text{CONV}} - t_d + 6$ ).

Table 20.6 shows the state for the A $\phi$ 1 clock. The value is calculated by multiplying the cycle time of A $\phi$  and the number of the state. The A $\phi$  should always be set to P $\phi$  or greater (P $\phi \leq$  A $\phi$ ) value.

**Table 20.5 Correspondence between Analog Input Channels and Groups being Allowed Simultaneous Sampling**

| A/D Converter Module   | Analog Input Channels | Group |

| A/D conversion time                                                          | ADBYPCR.SH = 0 | $t_{CONV}$  | $50n + 15*3$     | —    | $50n + 19*3$     |
|                                                                              | ADBYPCR.SH = 1 |             | $50n + 45*3$     | —    | $50n + 49*3$     |

- Notes: 1. A/D activation by MTU2, MTU2S trigger signal  
 2. A/D activation by the external trigger signal  
 3. n is a number of channel (n = 1 to 4)

**Figure 20.6 A/D Conversion Timing**

## 20.4.4 A/D Converter Activation by MTU2 and MTU2S

A/D conversion is activated by the A/D conversion start triggers (TRGAN, TRG0N, TRG4N, and TRG4BN) from the MTU2 and A/D conversion start triggers (TRGAN, TRG4AN, and TRG4BN) from the MTU2S. To enable this function, set the TRGE bit in ADCR to 1 and clear the EXTRG bit to 0. After this setting is made, if an A/D conversion start trigger from the MTU2 or MTU2S is generated, the ADST bit is set to 1. The time between the setting of the ADST bit to 1 and the start of the A/D conversion is the same as when A/D conversion is activated by writing 1 to the ADST bit by software.

## 20.4.5 External Trigger Input Timing

The A/D conversion can also be externally triggered. To input an external trigger, set the pin function controller (PFC) to select the  $\overline{\text{ADTRG}}$  pin function, drive the  $\overline{\text{ADTRG}}$  pin high, set the TRGE bit to 1 in ADCR, clear the ADST bit to 0, and set the EXTRG bit to 1. In this state, input a trigger through the  $\overline{\text{ADTRG}}$  pin. A falling edge of the  $\overline{\text{ADTRG}}$  signal sets the ADST bit to 1 in ADCR, starting the A/D conversion. Other operations are conducted in the same way as when A/D conversion is activated by writing 1 to the ADST bit by software. Figure 20.7 shows the timing.

The ADST bit is set to 1 after  $((5 - n)P\phi)$  states have elapsed from the point at which the A/D converter detects a falling edge on the  $\overline{\text{ADTRG}}$  pin.

Notes: \*

|       |                            |
|-------|----------------------------|
| n = 0 | when $P\phi : A\phi = 1:1$ |
| n = 1 | when $P\phi : A\phi = 1:2$ |
| n = 2 | when $P\phi : A\phi = 1:4$ |

Figure 20.7 External Trigger Input Timing

### 20.4.6 Example of ADDR Auto-Clear Function

When the A/D data register (ADDR) is read by the CPU or DMAC, ADDR can be automatically cleared to H'0000 by setting the ACE bit in ADCR to 1. This function allows the detection of non-updated ADDR states.

Figure 20.8 shows an example of when the auto-clear function of ADDR is disabled (normal state) and enabled.

When the ACE bit is 0 (initial value) and the A/D conversion result (H'0222) is not written to ADDR for some reason, the old data (H'0111) becomes the ADDR value. In addition, when the ADDR value is read into a general register using an A/D conversion end interrupt, the old data (H'0111) is stored in the general register. To detect a renewal failure, every time the old data needs to be stored in the RAM, a general register, etc.

When the ACE bit is 1, reading ADDR = H'0111 by the CPU, DMAC, or DTC automatically clears ADDR to H'0000. After this, if the A/D conversion result (H'0222) cannot be transferred to ADDR for some reason, the cleared data (H'0000) remains as the ADDR value. When this ADDR value is read into a general register, H'0000 is stored in the general register. Just by checking whether the read data value is H'0000 or not allows the detection of non-updated ADDR states.

- ACE bit = 0 (Normal condition: Auto-clear function is disabled.)

- ACE bit = 1 (Auto-clear function is enabled.)

**Figure 20.8 Example of When ADDR Auto-clear Function is Disabled (Normal Condition)/Enabled**

## 20.5 Interrupt Sources and DMAC or DTC Transfer Requests

The A/D converter generates A/D conversion end interrupts (ADI). An ADI interrupt generation is enabled when the ADIE bit in ADCR is set to 1. The DMAC or DTC can be activated by the DMAC or DTC setting when an ADI interrupt is generated. At this time, no interrupt to the CPU is generated. When the DMAC or DTC is activated by an ADI interrupt, the ADF bit in ADSR is automatically cleared at the data transfer by the DMAC or DTC.

**Table 20.7 AD Interrupt Sources**

| <b>A/D Converter Module</b> | <b>Name</b> | <b>DMAC Activation Request</b> | <b>DTC Activation Request</b> |
|-----------------------------|-------------|--------------------------------|-------------------------------|
| A/D converter module 0      | ADI0        | Available                      | Available                     |
| A/D converter module 1      | ADI1        | Not available                  | Available                     |

## 20.6 Definitions of A/D Conversion Accuracy

This LSI's A/D conversion accuracy definitions are given below.

- Resolution  
The number of A/D converter digital conversion output codes
- Offset error  
The deviation of the actual A/D conversion characteristic from the ideal A/D conversion characteristic when the digital output value changes from the minimum voltage value (zero voltage) B'000000000000 to B'000000000001. Does not include a quantization error (see figure 20.9).
- Full-scale error  
The deviation of the actual A/D conversion characteristic from the ideal A/D conversion characteristic when the digital output value changes from B'111111111110 to the maximum voltage value (full-scale voltage) B'111111111111. Does not include a quantization error (see figure 20.9).
- Quantization error  
The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 20.9).
- Nonlinearity error  
The deviation of the actual A/D conversion characteristic from the ideal A/D conversion characteristic between zero voltage and full-scale voltage. Does not include offset error, full-scale error, or quantization error (see figure 20.9).
- Absolute accuracy  
The deviation between the digital value and the analog input value. Includes offset error, full-scale error, quantization error, and nonlinearity error.

**Figure 20.9 Definitions of A/D Conversion Accuracy**

## 20.7 Usage Notes

### 20.7.1 Analog Input Voltage Range

The voltage applied to analog input pin (ANn) during A/D conversion should be in the range  $AV_{SS} \leq ANn (n = 0 \text{ to } 7) \leq AV_{REF}$ .

### 20.7.2 Relationship between AVcc, AVss and VccQ, Vss

When using the A/D converter, set  $AV_{CC} = 5.0 \text{ V} \pm 0.5 \text{ V}$  and  $AV_{SS} = V_{SS}$ . When the A/D converter is not used, set  $V_{CCQ} \leq AV_{CC} \leq 5.0 \text{ V} \pm 0.5 \text{ V}$ ,  $AV_{SS} = V_{SS}$ , and do not leave the AVcc pin open.

### 20.7.3 Range of AVREF Pin Settings

Set  $AV_{REF} = 4.5 \text{ V}$  to  $AV_{CC}$  when using the A/D converter, or set  $AV_{REF} = AV_{CC}$  when not using the A/D converter. Set  $AV_{REFVSS} = AV_{SS}$ , and do not leave the AVREFVSS pin open. If these conditions are not met, the reliability of the LSI may be adversely affected.

### 20.7.4 Notes on Board Design

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and the layout in which the digital circuit signal lines and analog circuit signal lines cross or are in close proximity to each other should be avoided as much as possible. Failure to do so may result in the incorrect operation of the analog circuitry due to inductance, adversely affecting the A/D conversion values.

In addition, digital circuitry must be isolated from the analog input signals (AN0 to AN7), analog reference power supply (AVREF), the analog power supply (AVcc), and the analog ground (AVss). AVss should be connected at one point to a stable digital ground (Vss) on the board.

## 20.7.5 Notes on Noise Countermeasures

To prevent damage due to an abnormal voltage, such as an excessive surge at the analog input pins (AN0 to AN7) and analog reference power supply (AVREF), a protection circuit should be connected between the AVcc and AVss, as shown in figure 20.10. The bypass capacitors connected to AVREF and the filter capacitor connected to ANn should be connected to the AVREFVSS. The 0.1- $\mu$ F capacitor in figure 20.10 should be placed close to the pin. If a filter capacitor is connected as shown in figure 20.10, the input currents at the analog input pin (ANn) are averaged, and an error may occur. Careful consideration is therefore required when deciding the circuit constants.

**Figure 20.10 Example of Analog Input Pin Protection Circuit**

## 20.7.6 Notes on Register Setting

- Set the ADST bit in the A/D control register (ADCR) after the A/D start trigger select register (ADSTRGR) and the A/D analog input channel select register (ADANSR) have been set.
- Do not modify the settings of the ADCS, ACE, ADIE, TRGE, and EXTRG bits while the ADST bit in the ADCR register is set to 1.
- Do not write 1 to the ADST bit while the ADST bit in the ADCR register is set to 1.
- Do not start the A/D conversion when the ANS bits (ANS[7:0]) in the A/D analog input channel select register (ADANSR) are all 0.

### 20.7.7 Permissible Signal Source Impedance

This LSI's analog input is designed such that conversion precision is guaranteed for an input signal for which the signal source impedance is 3 k $\Omega$  or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds 3 k $\Omega$ , charging may be insufficient and it may not be possible to guarantee A/D conversion precision. However, for A/D conversion in single mode with a large capacitance provided externally for A/D conversion in single mode, the input load will essentially comprise only the internal input resistance of 10 k $\Omega$ , and the signal source impedance is ignored. However, as a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g., 5 mV/ $\mu$ s or greater). When converting a high-speed analog signal or in scan mode, a low-impedance buffer should be inserted.

### 20.7.8 Influences on Absolute Precision

Adding capacitance results in coupling with GND, and therefore noise in GND may adversely affect absolute precision. Be sure to make the connection to an electrically stable GND such as AVss.

Care is also required to insure that filter circuits do not communicate with digital signals on the mounting board (i.e., acting as antennas).

### 20.7.9 Notes when Two A/D Modules Run Simultaneously

This LSI has two A/D modules. When two modules run simultaneously, or if the conversion of the next A/D module is started during the conversion of the first A/D module, as shown in figures 20.11 and 20.12, the guaranteed absolute precision of the A/D conversion module which has been activated first will be the values as listed in tables 20.8 and 20.9. The absolute precision depends on the cycle difference ( $T_{AD0-AD1}$  in figures 20.11 and 20.12) between the start of the first activated A/D conversion and the one of the next activated A/D conversion. Therefore, evaluate the specifications fully when two or more A/D modules are run simultaneously.

**Figure 20.11 A/D Conversion Start Timing between A/D\_0 Converter and A/D\_1 Converter (Sample-and-Hold Circuits Disabled in A/D\_0 and A/D\_1)**

**Figure 20.12 A/D Conversion Start Timing between A/D\_0 Converter and A/D\_1 Converter (Sample-and-Hold Circuit Enabled in A/D\_0)**

**Table 20.8 Absolute Precision and A/D Conversion Start Cycle Difference,  $T_{AD0-AD1}$  ( $A\phi$ ) between A/D\_0 and A/D\_1 in Figure 20.11**

|                    | $T_{AD0-AD1}$                 | Unit            |
|--------------------|-------------------------------|-----------------|
|                    | 0 to 15, 21 to 30, 45 or more | $A\phi$ (clock) |
| Absolute precision | $\pm 8$                       | LSB             |

- Notes: 1. This table lists the A/D\_0 absolute precision when the converter of A/D\_0 is started first.
2. The precision of A/D\_1 is  $\pm 8$ LSB regardless of  $T_{AD0-AD1}$  when the converter of A/D\_0 is started first.
3. When the conversion of A/D\_0 and A/D\_1 is started simultaneously, the absolute precision values of A/D\_0 and A/D\_1 are  $\pm 8$ LSB because  $T_{AD0-AD1} = 0$ .
4. When two A/D modules run simultaneously, the absolute precision of the first activated A/D is not guaranteed except for  $T_{AD0-AD1}^*$ .
5. When A/D\_0 and A/D\_1 are activated separately, each of  $T_{AD0-AD1}$  values is 45 or more. Thus, the absolute precision values of A/D\_0 and A/D\_1 are  $\pm 8$ LSB.

**Table 20.9 Absolute Precision and A/D Conversion Start Cycle Difference,  $T_{AD0-AD1}$  ( $A\phi$ ) between A/D\_0 and A/D\_1 in Figure 20.12**

|                    | $T_{AD0-AD1}$                                      | Unit            |
|--------------------|----------------------------------------------------|-----------------|
|                    | 0 to 15, 33 to 45, 55 to 65, 83 to 95, 107 or more | $A\phi$ (clock) |
| Absolute precision | $\pm 8$                                            | LSB             |

- Notes: 1. This table lists the A/D\_0 absolute precision when the converter of A/D\_0 is started first.
2. The precision of A/D\_1 is  $\pm 8$ LSB regardless of  $T_{AD0-AD1}$  when the converter of A/D\_0 is started first.
3. When the conversion of A/D\_0 and A/D\_1 is started simultaneously, the absolute precision values of A/D\_0 and A/D\_1 are  $\pm 8$ LSB because  $T_{AD0-AD1} = 0$ .
4. When two A/D modules run simultaneously, the absolute precision of the first activated A/D is not guaranteed except for  $T_{AD0-AD1}^*$ .
5. When A/D\_0 and A/D\_1 are activated separately, each of  $T_{AD0-AD1}$  values is 107 or more. Thus, the absolute precision values of A/D\_0 and A/D\_1 are  $\pm 8$ LSB.

## Section 21 Controller Area Network (RCAN-ET)

### 21.1 Summary

#### 21.1.1 Overview

This document primarily describes the programming interface for the RCAN-ET module. It serves to facilitate the hardware/software interface so that engineers involved in the RCAN-ET implementation can ensure the design is successful.

#### 21.1.2 Scope

The CAN Data Link Controller function is not described in this document. It is the responsibility of the reader to investigate the CAN Specification Document (see references). The interfaces from the CAN Controller are described, in so far as they pertain to the connection with the User Interface.

The programming model is described in some detail. It is not the intention of this document to describe the implementation of the programming interface, but to simply present the interface to the underlying CAN functionality.

The document places no constraints upon the implementation of the RCAN-ET module in terms of process, packaging or power supply criteria. These issues are resolved where appropriate in implementation specifications.

#### 21.1.3 Audience

In particular this document provides the design reference for software authors who are responsible for creating a CAN application using this module.

In the creation of the RCAN-ET user interface LSI engineers must use this document to understand the hardware requirements.

### 21.1.4 References

1. CAN Licence Specification, Robert Bosch GmbH, 1992
2. CAN Specification Version 2.0 part A, Robert Bosch GmbH, 1991
3. CAN Specification Version 2.0 part B, Robert Bosch GmbH, 1991
4. Implementation Guide for the CAN Protocol, CAN Specification 2.0 Addendum, CAN In Automation, Erlangen, Germany, 1997

### 21.1.5 Features

- supports CAN specification 2.0B
- Bit timing compliant with ISO-11898-1
- 16 Mailbox version
- Clock 20 to 50 MHz
- 15 programmable Mailboxes for transmit / receive + 1 receive-only mailbox
- sleep mode for low power consumption and automatic recovery from sleep mode by detecting CAN bus activity
- programmable receive filter mask (standard and extended identifier) supported by all Mailboxes
- programmable CAN data rate up to 1MBit/s
- transmit message queuing with internal priority sorting mechanism against the problem of priority inversion for real-time applications
- data buffer access without SW handshake requirement in reception
- flexible micro-controller interface
- flexible interrupt structure

## 21.2 Architecture

The RCAN-ET device offers a flexible and sophisticated way to organise and control CAN frames, providing the compliance to CAN2.0B Active and ISO-11898-1. The module is formed from 5 different functional entities. These are the Micro Processor Interface (MPI), Mailbox, Mailbox Control and CAN Interface. The figure below shows the block diagram of the RCAN-ET Module. The bus interface timing is designed according to the peripheral bus I/F required for each product.

Figure 21.1 RCAN-ET Architecture

**Important:** Although core of RCAN-ET is designed based on a 32-bit bus system, the whole RCAN-ET including MPI for the CPU has 16-bit bus interface to CPU. In that case, LongWord (32-bit) access must be implemented as 2 consecutive word (16-bit) accesses. In this manual, LongWord access means the two consecutive accesses.

- **Micro Processor Interface (MPI)**

The MPI allows communication between the Renesas CPU and RCAN-ET's registers/mailboxes to control the memory interface. It also contains the Wakeup Control logic that detects the CAN bus activities and notifies the MPI and the other parts of RCAN-ET so that the RCAN-ET can automatically exit the Sleep mode.

It contains registers such as MCR, IRR, GSR and IMR.

- **Mailbox**

The Mailboxes consists of RAM configured as message buffers and registers. There are 16 Mailboxes, and each mailbox has the following information.

<RAM>

- CAN message control (identifier, rtr, ide, etc)
- CAN message data (for CAN Data frames)
- Local Acceptance Filter Mask for reception

<Registers>

- CAN message control (dlc)
- 3-bit wide Mailbox Configuration, Disable Automatic Re-Transmission bit, Auto-Transmission for Remote Request bit, New Message Control bit

- **Mailbox Control**

The Mailbox Control handles the following functions:

- For received messages, compare the IDs and generate appropriate RAM addresses/data to store messages from the CAN Interface into the Mailbox and set/clear appropriate registers accordingly.
- To transmit messages, RCAN-ET will run the internal arbitration to pick the correct priority message, and load the message from the Mailbox into the Tx-buffer of the CAN Interface and set/clear appropriate registers accordingly.
- Arbitrates Mailbox accesses between the CPU and the Mailbox Control.
- Contains registers such as TXPR, TXCR, TXACK, ABACK, RXPR, RFPR, UMSR and MBIMR.

- **CAN Interface**

This block conforms to the requirements for a CAN Bus Data Link Controller which is specified in Ref. [2, 4]. It fulfils all the functions of a standard DLC as specified by the OSI 7 Layer Reference model. This functional entity also provides the registers and the logic which are specific to a given CAN bus, which includes the Receive Error Counter, Transmit Error Counter, the Bit Configuration Registers and various useful Test Modes. This block also contains functional entities to hold the data received and the data to be transmitted for the

CAN Data Link Controller.

## 21.3 Programming Model - Overview

The purpose of this programming interface is to allow convenient, effective access to the CAN bus for efficient message transfer. Please bear in mind that the user manual reports all settings allowed by the RCAN-ET IP. Different use of RCAN-ET is not allowed.

### 21.3.1 Memory Map

The diagram of the memory map is shown below.

Figure 21.2 RCAN-ET Memory Map

The locations not used (between H'000 and H'2F2) are reserved and cannot be accessed.

### 21.3.2 Mailbox Structure

Mailboxes play a role as message buffers to transmit / receive CAN frames. Each Mailbox is comprised of 3 identical storage fields that are 1): Message Control, 2): Local Acceptance Filter Mask, 3): Message Data. The following table shows the address map for the control, LAFM, data and addresses for each mailbox.

| Mailbox          | Address   |           |           |           |
|------------------|-----------|-----------|-----------|-----------|
|                  | Control0  | LAFM      | Data      | Control1  |
|                  | 4 bytes   | 4 bytes   | 8 bytes   | 2 bytes   |
| 0 (Receive Only) | 100 – 103 | 104 – 107 | 108 – 10F | 110 – 111 |
| 1                | 120 – 123 | 124 – 127 | 128 – 12F | 130 – 131 |
| 2                | 140 – 143 | 144 – 147 | 148 – 14F | 150 – 151 |
| 3                | 160 – 163 | 164 – 167 | 168 – 16F | 170 – 171 |
| 4                | 180 – 183 | 184 – 187 | 188 – 18F | 190 – 191 |
| 5                | 1A0 – 1A3 | 1A4 – 1A7 | 1A8 – 1AF | 1B0 – 1B1 |
| 6                | 1C0 – 1C3 | 1C4 – 1C7 | 1C8 – 1CF | 1D0 – 1D1 |
| 7                | 1E0 – 1E3 | 1E4 – 1E7 | 1E8 – 1EF | 1F0 – 1F1 |
| 8                | 200 – 203 | 204 – 207 | 208 – 20F | 210 – 211 |
| 9                | 220 – 223 | 224 – 227 | 228 – 22F | 230 – 231 |
| 10               | 240 – 243 | 244 – 247 | 248 – 24F | 250 – 251 |
| 11               | 260 – 263 | 264 – 267 | 268 – 26F | 270 – 271 |
| 12               | 280 – 283 | 284 – 287 | 288 – 28F | 290 – 291 |
| 13               | 2A0 – 2A3 | 2A4 – 2A7 | 2A8 – 2AF | 2B0 – 2B1 |
| 14               | 2C0 – 2C3 | 2C4 – 2C7 | 2C8 – 2CF | 2D0 – 2D1 |
| 15               | 2E0 – 2E3 | 2E4 – 2E7 | 2E8 – 2EF | 2F0 – 2F1 |

Mailbox-0 is a receive-only box, and all the other Mailboxes can operate as both receive and transmit boxes, dependant upon the MBC (Mailbox Configuration) bits in the Message Control. The following diagram shows the structure of a Mailbox in detail.

**Table 21.1 Roles of Mailboxes**

|        | <b>Tx</b> | <b>Rx</b> |
|--------|-----------|-----------|
| MB15-1 | OK        | OK        |
| MB0    | —         | OK        |

**Figure 21.3 Mailbox-N Structure**

- Notes:
1. All bits shadowed in grey are reserved and must be written LOW. The value returned by a read may not always be '0' and should not be relied upon.
  2. ATX and DART are not supported by Mailbox-0, and the MBC setting of Mailbox-0 is limited.
  3. ID Reorder (MCR15) can change the order of STDID, RTR, IDE and EXTID of both message control and LAFM.

## (1) Message Control Field

**STID[10:0]:** These bits set the identifier (standard identifier) of data frames and remote frames.

**EXTID[17:0]:** These bits set the identifier (extended identifier) of data frames and remote frames.

**RTR** (Remote Transmission Request bit) : Used to distinguish between data frames and remote frames. This bit is overwritten by received CAN Frames depending on Data Frames or Remote Frames.

**Important:** Please note that, when ATX bit is set with the setting MBC=001(bin), the RTR bit will never be set. When a Remote Frame is received, the CPU can be notified by the corresponding RFPR set or IRR[2] (Remote Frame Request Interrupt), however, as RCAN-ET needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** In order to support automatic answer to remote frame when MBC=001(bin) is used and ATX=1 the RTR flag must be programmed to zero to allow data frame to be transmitted.

Note: when a Mailbox is configured to send a remote frame request the DLC used for transmission is the one stored into the Mailbox.

| RTR | Description  |
|-----|--------------|
| 0   | Data frame   |
| 1   | Remote frame |

**IDE** (Identifier Extension bit) : Used to distinguish between the standard format and extended format of CAN data frames and remote frames.

| IDE | Description     |
|-----|-----------------|
| 0   | Standard format |
| 1   | Extended format |

- Mailbox-0

|                |    |    |     |    |    |          |     |     |   |   |   |   |          |     |     |     |
|----------------|----|----|-----|----|----|----------|-----|-----|---|---|---|---|----------|-----|-----|-----|
| Bit:           | 15 | 14 | 13  | 12 | 11 | 10       | 9   | 8   | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|                | 0  | 0  | NMC | 0  | 0  | MBC[2:0] |     |     | 0 | 0 | 0 | 0 | DLC[3:0] |     |     |     |
| Initial value: | 0  | 0  | 0   | 0  | 0  | 1        | 1   | 1   | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   |
| R/W:           | R  | R  | R/W | R  | R  | R/W      | R/W | R/W | R | R | R | R | R/W      | R/W | R/W | R/W |

Note: MBC[1] of MB0 is always "1".

- Mailbox-15 to 1

|                |    |    |     |     |      |          |     |     |   |   |   |   |          |     |     |     |
|----------------|----|----|-----|-----|------|----------|-----|-----|---|---|---|---|----------|-----|-----|-----|
| Bit:           | 15 | 14 | 13  | 12  | 11   | 10       | 9   | 8   | 7 | 6 | 5 | 4 | 3        | 2   | 1   | 0   |
|                | 0  | 0  | NMC | ATX | DART | MBC[2:0] |     |     | 0 | 0 | 0 | 0 | DLC[3:0] |     |     |     |
| Initial value: | 0  | 0  | 0   | 0   | 0    | 1        | 1   | 1   | 0 | 0 | 0 | 0 | 0        | 0   | 0   | 0   |
| R/W:           | R  | R  | R/W | R/W | R/W  | R/W      | R/W | R/W | R | R | R | R | R/W      | R/W | R/W | R/W |

**NMC (New Message Control):** When this bit is set to '0', the Mailbox of which the RXPR or RFPR bit is already set does not store the new message but maintains the old one and sets the UMSR correspondent bit. When this bit is set to '1', the Mailbox of which the RXPR or RFPR bit is already set overwrites with the new message and sets the UMSR correspondent bit.

**Important:** Please note that if a remote frame is overwritten with a data frame or vice versa could be that both RXPR and RFPR flags (together with UMSR) are set for the same Mailbox. In this case the RTR bit within the Mailbox Control Field should be relied upon.

| NMC | Description                  |
|-----|------------------------------|
| 0   | Overrun mode (Initial value) |
| 1   | Overwrite mode               |

**ATX (Automatic Transmission of Data Frame):** When this bit is set to '1' and a Remote Frame is received into the Mailbox DLC is stored. Then, a Data Frame is transmitted from the same Mailbox using the current contents of the message data and updated DLC by setting the corresponding TXPR automatically. The scheduling of transmission is still governed by ID priority or Mailbox priority as configured with the Message Transmission Priority control bit (MCR.2). In order to use this function, MBC[2:0] needs to be programmed to be '001' (Bin). When a transmission is performed by this function, the DLC (Data Length Code) to be used is the one that has been received. Application needs to guarantee that the DLC of the remote frame correspond to the DLC of the data frame requested.

**Important:** When ATX is used and MBC=001 (Bin) the filter for the IDE bit cannot be used since ID of remote frame has to be exactly the same as that of data frame as the reply message.

**Important:** Please note that, when this function is used, the RTR bit will never be set despite receiving a Remote Frame. When a Remote Frame is received, the CPU will be notified by the corresponding RFPR set, however, as RCAN-ET needs to transmit the current message as a Data Frame, the RTR bit remains unchanged.

**Important:** Please note that in case of overrun condition (UMSR flag set when the Mailbox has its NMC = 0) the message received is discarded. In case a remote frame is causing overrun into a Mailbox configured with ATX = 1, the transmission of the corresponding data frame may be triggered only if the related RFPR flag is cleared by the CPU when the UMSR flag is set. In such case RFPR flag would get set again.

| ATX | Description                                                   |
|-----|---------------------------------------------------------------|
| 0   | Automatic Transmission of Data Frame disabled (Initial value) |
| 1   | Automatic Transmission of Data Frame enabled                  |

**DART (Disable Automatic Re-Transmission):** When this bit is set, it disables the automatic re-transmission of a message in the event of an error on the CAN bus or an arbitration lost on the CAN bus. In effect, when this function is used, the corresponding TXCR bit is automatically set at the start of transmission. When this bit is set to '0', RCAN-ET tries to transmit the message as many times as required until it is successfully transmitted or it is cancelled by the TXCR.

| DART | Description                             |
|------|-----------------------------------------|
| 0    | Re-transmission enabled (Initial value) |
| 1    | Re-Transmission disabled                |

**MBC[2:0] (Mailbox Configuration):** These bits configure the nature of each Mailbox as follows. When MBC=111 (Bin), the Mailbox is inactive, i.e., it does not receive or transmit a message regardless of TXPR or other settings. The MBC='110', '101' and '100' settings are prohibited. When the MBC is set to any other value, the LAFM field becomes available. Please don't set TXPR when MBC is set as reception. There is no hardware protection, and TXPR remains set. MBC[1] of Mailbox-0 is fixed to "1" by hardware. This is to ensure that MB0 cannot be configured to transmit Messages.

| MBC[2] | MBC[1] | MBC[0] | Data<br>Frame<br>Transmit        | Remote<br>Frame<br>Transmit | Data<br>Frame<br>Receive | Remote<br>Frame<br>Receive | Remarks                                                                                                                              |
|--------|--------|--------|----------------------------------|-----------------------------|--------------------------|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 0      | 0      | 0      | Yes                              | Yes                         | No                       | No                         | <ul style="list-style-type: none"> <li>Not allowed for Mailbox-0</li> </ul>                                                          |
| 0      | 0      | 1      | Yes                              | Yes                         | No                       | Yes                        | <ul style="list-style-type: none"> <li>Can be used with ATX*</li> <li>Not allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul> |
| 0      | 1      | 0      | No                               | No                          | Yes                      | Yes                        | <ul style="list-style-type: none"> <li>Allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul>                                    |
| 0      | 1      | 1      | No                               | No                          | Yes                      | No                         | <ul style="list-style-type: none"> <li>Allowed for Mailbox-0</li> <li>LAFM can be used</li> </ul>                                    |
| 1      | 0      | 0      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 0      | 1      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 1      | 0      | Setting prohibited               |                             |                          |                            |                                                                                                                                      |
| 1      | 1      | 1      | Mailbox inactive (Initial value) |                             |                          |                            |                                                                                                                                      |

Notes: \* In order to support automatic retransmission, RTR shall be "0" when MBC=001(bin) and ATX=1.

When ATX=1 is used the filter for IDE must not be used

**DLC[3:0] (Data Length Code):** These bits encode the number of data bytes from 0,1, 2, ... 8 that will be transmitted in a data frame. Please note that when a remote frame request is transmitted the DLC value to be used must be the same as the DLC of the data frame that is requested.

| DLC[3] | DLC[2] | DLC[1] | DLC[0] | Description                           |
|--------|--------|--------|--------|---------------------------------------|
| 0      | 0      | 0      | 0      | Data Length = 0 bytes (Initial value) |
| 0      | 0      | 0      | 1      | Data Length = 1 byte                  |
| 0      | 0      | 1      | 0      | Data Length = 2 bytes                 |
| 0      | 0      | 1      | 1      | Data Length = 3 bytes                 |
| 0      | 1      | 0      | 0      | Data Length = 4 bytes                 |
| 0      | 1      | 0      | 1      | Data Length = 5 bytes                 |
| 0      | 1      | 1      | 0      | Data Length = 6 bytes                 |
| 0      | 1      | 1      | 1      | Data Length = 7 bytes                 |
| 1      | x      | x      | x      | Data Length = 8 bytes                 |

(2)    **Local Acceptance Filter Mask (LAFM)**

This area is used as Local Acceptance Filter Mask (LAFM) for receive boxes.

**LAFM:** When MBC is set to 001, 010, 011 (Bin), this field is used as LAFM Field. It allows a Mailbox to accept more than one identifier. The LAFM is comprised of two 16-bit read/write areas as follows.

**Figure 21.4    Acceptance Filter**

If a bit is set in the LAFM, then the corresponding bit of a received CAN identifier is ignored when the RCAN-ET searches a Mailbox with the matching CAN identifier. If the bit is cleared, then the corresponding bit of a received CAN identifier must match to the STDID/IDE/EXTID set in the mailbox to be stored. The structure of the LAFM is same as the message control in a Mailbox. If this function is not required, it must be filled with ‘0’.

**Important:** RCAN-ET starts to find a matching identifier from Mailbox-15 down to Mailbox-0. As soon as RCAN-ET finds one matching, it stops the search. The message will be stored or not depending on the NMC and RXPR/RFPR flags. This means that, even using LAFM, a received message can only be stored into 1 Mailbox.

**Important:** When a message is received and a matching Mailbox is found, the whole message is stored into the Mailbox. This means that, if the LAFM is used, the STDID, RTR, IDE and EXTID may differ to the ones originally set as they are updated with the STDID, RTR, IDE and EXTID of the received message.

**STD\_LAFM[10:0]** — Filter mask bits for the CAN base identifier [10:0] bits.

| STD_LAFM[10:0] | Description                               |
|----------------|-------------------------------------------|
| 0              | Corresponding STD_ID bit is cared         |
| 1              | Corresponding STD_ID bit is "don't cared" |

**EXT\_LAFM[17:0]** — Filter mask bits for the CAN Extended identifier [17:0] bits.

| <b>EXT_LAFM[17:0]</b> | <b>Description</b>                        |
|-----------------------|-------------------------------------------|
| 0                     | Corresponding EXT_ID bit is cared         |
| 1                     | Corresponding EXT_ID bit is "don't cared" |

**IDE\_LAFM** — Filter mask bit for the CAN IDE bit.

| <b>IDE_LAFM</b> | <b>Description</b>                        |
|-----------------|-------------------------------------------|
| 0               | Corresponding IDE_ID bit is cared         |
| 1               | Corresponding IDE_ID bit is "don't cared" |

### (3) Message Data Fields

Storage for the CAN message data that is transmitted or received. MSG\_DATA[0] corresponds to the first data byte that is transmitted or received. The bit order on the CAN bus is bit 7 through to bit 0.

#### 21.3.3 RCAN-ET Control Registers

The following sections describe RCAN-ET control registers. The address is mapped as follow.

**Important:** These registers can only be accessed in Word size (16-bit).

| <b>Description</b>           | <b>Address</b> | <b>Name</b> | <b>Access Size (bits)</b> |
|------------------------------|----------------|-------------|---------------------------|
| Master Control Register      | 000            | MCR         | Word                      |
| General Status Register      | 002            | GSR         | Word                      |
| Bit Configuration Register 1 | 004            | BCR1        | Word                      |
| Bit Configuration Register 0 | 006            | BCR0        | Word                      |
| Interrupt Request Register   | 008            | IRR         | Word                      |
| Interrupt Mask Register      | 00A            | IMR         | Word                      |
| Error Counter Register       | 00C            | TEC/REC     | Word                      |

**Figure 21.5 RCAN-ET Control Registers**

## (1) Master Control Register (MCR)

The Master Control Register (MCR) is a 16-bit read/write register that controls RCAN-ET.

- MCR (Address = H'000)

|                |       |       |    |    |    |          |     |      |      |      |     |   |      |      |      |     |
|----------------|-------|-------|----|----|----|----------|-----|------|------|------|-----|---|------|------|------|-----|
| Bit:           | 15    | 14    | 13 | 12 | 11 | 10       | 9   | 8    | 7    | 6    | 5   | 4 | 3    | 2    | 1    | 0   |

| Initial value: | 1     | 0     | 0  | 0  | 0  | 0        | 0   | 0    | 0    | 0    | 0   | 0 | 0    | 0    | 0    | 1   |
| R/W:           | R/W   | R/W   | R  | R  | R  | R/W      | R/W | R/W  | R/W  | R/W  | R/W | R | R    | R/W  | R/W  | R/W |

**Bit 15 — ID Reorder (MCR15):** This bit changes the order of STDID, RTR, IDE and EXTID of both message control and LAFM.

### Bit15 : MCR15      Description

0      RCAN-ET is the same as HCAN2

1      RCAN-ET is not the same as HCAN2 (Initial value)

| MCR15 (ID Reorder) = 0 |                  |                  |    |    |    |    |   |   |   |   |   |   |     |          |                    |   |         |            |
|------------------------|------------------|------------------|----|----|----|----|---|---|---|---|---|---|-----|----------|--------------------|---|---------|------------|
|                        | 15               | 14               | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3   | 2        | 1                  | 0 |         |            |
| H'100 + N*32           | 0                | STDID[10:0]      |    |    |    |    |   |   |   |   |   |   | RTR | IDE      | EXTID[17:16]       |   | Word/LW | Control 0  |
| H'102 + N*32           | EXTID[15:0]      |                  |    |    |    |    |   |   |   |   |   |   |     | Word     |                    |   |         |            |
| H'104 + N*32           | 0                | STDID_LAFM[10:0] |    |    |    |    |   |   |   |   |   |   | 0   | IDE_LAFM | EXTID_LAFM [17:16] |   | Word/LW | LAFM Field |
| H'106 + N*32           | EXTID_LAFM[15:0] |                  |    |    |    |    |   |   |   |   |   |   |     | Word     |                    |   |         |            |

| MCR15 (ID Reorder) = 1 |                  |     |    |                  |    |    |   |   |   |   |   |   |   |      |                    |   |         |            |
|------------------------|------------------|-----|----|------------------|----|----|---|---|---|---|---|---|---|------|--------------------|---|---------|------------|
|                        | 15               | 14  | 13 | 12               | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2    | 1                  | 0 |         |            |
| H'100 + N*32           | IDE              | RTR | 0  | STDID[10:0]      |    |    |   |   |   |   |   |   |   |      | EXTID[17:16]       |   | Word/LW | Control 0  |
| H'102 + N*32           | EXTID[15:0]      |     |    |                  |    |    |   |   |   |   |   |   |   | Word |                    |   |         |            |
| H'104 + N*32           | IDE_LAFM         | 0   | 0  | STDID_LAFM[10:0] |    |    |   |   |   |   |   |   |   |      | EXTID_LAFM [17:16] |   | Word/LW | LAFM Field |
| H'106 + N*32           | EXTID_LAFM[15:0] |     |    |                  |    |    |   |   |   |   |   |   |   | Word |                    |   |         |            |

**Figure 21.6 ID Reorder**

This bit can be modified only in reset mode.

**Bit 14 — Auto Halt Bus Off (MCR14):** If both this bit and MCR6 are set, MCR1 is automatically set as soon as RCAN-ET enters BusOff.

| Bit14 : MCR14 | Description                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------|
| 0             | RCAN-ET remains in BusOff for normal recovery sequence (128 x 11 Recessive Bits) (Initial value) |
| 1             | RCAN-ET moves directly into Halt Mode after it enters BusOff if MCR6 is set.                     |

This bit can be modified only in reset mode.

**Bit 13 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 12 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 11 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 10 - 8 — Test Mode (TST[2:0]):** This bit enables/disables the test modes. Please note that before activating the Test Mode it is requested to move RCAN-ET into Halt mode or Reset mode. This is to avoid that the transition to Test Mode could affect a transmission/reception in progress. For details, please refer to section 21.4.1, Test Mode Settings.

Please note that the test modes are allowed only for diagnosis and tests and not when RCAN-ET is used in normal operation.

| Bit10:<br>TST2 | Bit9:<br>TST1 | Bit8:<br>TST0 | Description                          |
|----------------|---------------|---------------|--------------------------------------|
| 0              | 0             | 0             | Normal Mode (initial value)          |
| 0              | 0             | 1             | Listen-Only Mode (Receive-Only Mode) |
| 0              | 1             | 0             | Self Test Mode 1 (External)          |
| 0              | 1             | 1             | Self Test Mode 2 (Internal)          |
| 1              | 0             | 0             | Write Error Counter                  |
| 1              | 0             | 1             | Error Passive Mode                   |
| 1              | 1             | 0             | setting prohibited                   |
| 1              | 1             | 1             | setting prohibited                   |

**Bit 7 — Auto-wake Mode (MCR7):** MCR7 enables or disables the Auto-wake mode. If this bit is set, the RCAN-ET automatically cancels the sleep mode (MCR5) by detecting CAN bus activity (dominant bit). If MCR7 is cleared the RCAN-ET does not automatically cancel the sleep mode.

RCAN-ET cannot store the message that wakes it up.

Note: MCR7 cannot be modified while in sleep mode.

| Bit7 : MCR7 | Description                                            |
|-------------|--------------------------------------------------------|
| 0           | Auto-wake by CAN bus activity disabled (Initial value) |
| 1           | Auto-wake by CAN bus activity enabled                  |

**Bit 6 — Halt during Bus Off (MCR6):** MCR6 enables or disables entering Halt mode immediately when MCR1 is set during Bus Off. This bit can be modified only in Reset or Halt mode. Please note that when Halt is entered in Bus Off the CAN engine is also recovering immediately to Error Active mode.

| Bit6 : MCR6 | Description                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------|
| 0           | If MCR[1] is set, RCAN-ET will not enter Halt mode during Bus Off but wait up to end of recovery sequence (Initial value) |
| 1           | Enter Halt mode immediately during Bus Off if MCR[1] or MCR[14] are asserted.                                             |

**Bit 5 — Sleep Mode (MCR5):** Enables or disables Sleep mode transition. If this bit is set, while RCAN-ET is in halt mode, the transition to sleep mode is enabled. Setting MCR5 is allowed after entering Halt mode. The two Error Counters (REC, TEC) will remain the same during Sleep mode. This mode will be exited in two ways:

1. by writing a '0' to this bit position,
2. or, if MCR[7] is enabled, after detecting a dominant bit on the CAN bus.

If Auto wake up mode is disabled, RCAN-ET will ignore all CAN bus activities until the sleep mode is terminated. When leaving this mode the RCAN-ET will synchronise to the CAN bus (by checking for 11 recessive bits) before joining CAN Bus activity. This means that, when the No.2 method is used, RCAN-ET will miss the first message to receive. CAN transceivers stand-by mode will also be unable to cope with the first message when exiting stand by mode, and the S/W needs to be designed in this manner.

In sleep mode only the following registers can be accessed: MCR, GSR, IRR and IMR.

**Important:** RCAN-ET is required to be in Halt mode before requesting to enter in Sleep mode. That allows the CPU to clear all pending interrupts before entering sleep mode. Once all interrupts are cleared RCAN-ET must leave the Halt mode and enter Sleep mode simultaneously (by writing MCR[5]=1 and MCR[1]=0 at the same time).

| Bit 5 : MCR5 | Description                                 |
|--------------|---------------------------------------------|
| 0            | RCAN-ET sleep mode released (Initial value) |
| 1            | Transition to RCAN-ET sleep mode enabled    |

**Bit 4 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 3 — Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 2 — Message Transmission Priority (MCR2):** MCR2 selects the order of transmission for pending transmit data. If this bit is set, pending transmit data are sent in order of the bit position in the Transmission Pending Register (TXPR). The order of transmission starts from Mailbox-15 as the highest priority, and then down to Mailbox-1 (if those mailboxes are configured for transmission).

If MCR2 is cleared, all messages for transmission are queued with respect to their priority (by running internal arbitration). The highest priority message has the Arbitration Field (STDID + IDE bit + EXTID (if IDE=1) + RTR bit) with the lowest digital value and is transmitted first. The internal arbitration includes the RTR bit and the IDE bit (internal arbitration works in the same way as the arbitration on the CAN Bus between two CAN nodes starting transmission at the same time).

This bit can be modified only in Reset or Halt mode.

| Bit 2 : MCR2 | Description                                                                       |
|--------------|-----------------------------------------------------------------------------------|
| 0            | Transmission order determined by message identifier priority (Initial value)      |
| 1            | Transmission order determined by mailbox number priority (Mailbox-15 → Mailbox-1) |

**Bit 1—Halt Request (MCR1):** Setting the MCR1 bit causes the CAN controller to complete its current operation and then enter Halt mode (where it is cut off from the CAN bus). The RCAN-ET remains in Halt Mode until the MCR1 is cleared. During the Halt mode, the CAN Interface does not join the CAN bus activity and does not store messages or transmit messages. All the user registers (including Mailbox contents and TEC/REC) remain unchanged with the exception of IRR0 and GSR4 which are used to notify the halt status itself. If the CAN bus is in idle or intermission state regardless of MCR6, RCAN-ET will enter Halt Mode within one Bit Time. If MCR6 is set, a halt request during Bus Off will be also processed within one Bit Time. Otherwise the full Bus Off recovery sequence will be performed beforehand. Entering the Halt Mode can be notified by IRR0 and GSR4.

If both MCR14 and MCR6 are set, MCR1 is automatically set as soon as RCAN-ET enters BusOff.

In the Halt mode, the RCAN-ET configuration can be modified with the exception of the Bit Timing setting, as it does not join the bus activity. MCR[1] has to be cleared by writing a '0' in order to re-join the CAN bus. After this bit has been cleared, RCAN-ET waits until it detects 11 recessive bits, and then joins the CAN bus.

**Note:** After issuing a Halt request the CPU is not allowed to set TXPR or TXCR or clear MCR1 until the transition to Halt mode is completed (notified by IRR0 and GSR4). After MCR1 is set this can be cleared only after entering Halt mode or through a reset operation (SW or HW).

**Note:** Transition into or recovery from HALT mode, is only possible if the BCR1 and BCR0 registers are configured to a proper Baud Rate.

| Bit 1 : MCR1 | Description                        |
|--------------|------------------------------------|
| 0            | Clear Halt request (Initial value) |
| 1            | Halt mode transition request       |

**Bit 0 — Reset Request (MCR0):** Controls resetting of the RCAN-ET module. When this bit is changed from '0' to '1' the RCAN-ET controller enters its reset routine, re-initialising the internal logic, which then sets GSR3 and IRR0 to notify the reset mode. During a re-initialisation, all user registers are initialised.

RCAN-ET can be re-configured while this bit is set. This bit has to be cleared by writing a '0' to join the CAN bus. After this bit is cleared, the RCAN-ET module waits until it detects 11 recessive bits, and then joins the CAN bus. The Baud Rate needs to be set up to a proper value in order to sample the value on the CAN Bus.

After Power On Reset, this bit and GSR3 are always set. This means that a reset request has been made and RCAN-ET needs to be configured.

The Reset Request is equivalent to a Power On Reset but controlled by Software.

| Bit 0 : MCR0 | Description                                                 |
|--------------|-------------------------------------------------------------|
| 0            | Clear Reset Request                                         |
| 1            | CAN Interface reset mode transition request (Initial value) |

## (2) General Status Register (GSR)

The General Status Register (GSR) is a 16-bit read-only register that indicates the status of RCAN-ET.

### • GSR (Address = H'002)

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5    | 4    | 3    | 2    | 1    | 0    |
|----------------|----|----|----|----|----|----|---|---|---|---|------|------|------|------|------|------|
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | GSR5 | GSR4 | GSR3 | GSR2 | GSR1 | GSR0 |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0    | 0    | 1    | 1    | 0    | 0    |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R    | R    | R    | R    | R    | R    |

**Bits 15 to 6: Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 5 — Error Passive Status Bit (GSR5):** Indicates whether the CAN Interface is in Error Passive or not. This bit will be set high as soon as the RCAN-ET enters the Error Passive state and is cleared when the module enters again the Error Active state (this means the GSR5 will stay high during Error Passive and during Bus Off). Consequently to find out the correct state both GSR5 and GSR0 must be considered.

| Bit 5 : GSR5 | Description                                                                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | RCAN-ET is not in Error Passive or in Bus Off status (Initial value)<br>[Reset condition] RCAN-ET is in Error Active state                                            |
| 1            | RCAN-ET is in Error Passive (if GSR0=0) or Bus Off (if GSR0=1)<br>[Setting condition] When $TEC \geq 128$ or $REC \geq 128$ or if Error Passive Test Mode is selected |

**Bit 4 — Halt/Sleep Status Bit (GSR4):** Indicates whether the CAN engine is in the halt/sleep state or not. Please note that the clearing time of this flag is not the same as the setting time of IRR12.

Please note that this flag reflects the status of the CAN engine and not of the full RCAN-ET IP. RCAN-ET exits sleep mode and can be accessed once MCR5 is cleared. The CAN engine exits sleep mode only after two additional transmission clocks on the CAN Bus.

| Bit 4 : GSR4 | Description                                                                                                                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | RCAN-ET is not in the Halt state or Sleep state (Initial value)                                                                                                                                                                                         |
| 1            | Halt mode (if MCR1=1) or Sleep mode (if MCR5=1)<br>[Setting condition] If MCR1 is set and the CAN bus is either in intermission or idle or MCR5 is set and RCAN-ET is in the halt mode or RCAN-ET is moving to Bus Off when MCR14 and MCR6 are both set |

**Bit 3 — Reset Status Bit (GSR3):** Indicates whether the RCAN-ET is in the reset state or not.

| Bit 3 : GSR3 | Description                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------|
| 0            | RCAN-ET is not in the reset state                                                                          |
| 1            | Reset state (Initial value)<br>[Setting condition] After an RCAN-ET internal reset (due to SW or HW reset) |

**Bit 2 — Message Transmission in progress Flag (GSR2):** Flag that indicates to the CPU if the RCAN-ET is in Bus Off or transmitting a message or an error/overload flag due to error detected during transmission. The timing to set TXACK is different from the time to clear GSR2. TXACK is set at the 7<sup>th</sup> bit of End Of Frame. GSR2 is set at the 3<sup>rd</sup> bit of intermission if there are no more messages ready to be transmitted. It is also set by arbitration lost, bus idle, reception, reset or halt transition.

| Bit 2 : GSR2 | Description                                                                        |
|--------------|------------------------------------------------------------------------------------|
| 0            | RCAN-ET is in Bus Off or a transmission is in progress                             |
| 1            | [Setting condition] Not in Bus Off and no transmission in progress (Initial value) |

Bit 1—Transmit/Receive Warning Flag (GSR1): Flag that indicates an error warning.

| Bit 1 : GSR1 | Description                                                                       |
|--------------|-----------------------------------------------------------------------------------|
| 0            | [Reset condition] When (TEC < 96 and REC < 96) or Bus Off (Initial value)         |
| 1            | [Setting condition] When $96 \leq \text{TEC} < 256$ or $96 \leq \text{REC} < 256$ |

Note: REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence. However the flag GSR1 is not set in Bus Off.

**Bit 0—Bus Off Flag (GSR0):** Flag that indicates that RCAN-ET is in the bus off state.

| Bit 0 : GSR0 | Description                                                                             |
|--------------|-----------------------------------------------------------------------------------------|
| 0            | [Reset condition] Recovery from bus off state or after a HW or SW reset (Initial value) |
| 1            | [Setting condition] When $\text{TEC} \geq 256$ (bus off state)                          |

Note: Only the lower 8 bits of TEC are accessible from the user interface. The 9<sup>th</sup> bit is equivalent to GSR0.

### (3) Bit Configuration Register (BCR0, BCR1)

The bit configuration registers (BCR0 and BCR1) are 2 X 16-bit read/write register that are used to set CAN bit timing parameters and the baud rate pre-scaler for the CAN Interface.

The Time quanta is defined as:

$$Timequanta = \frac{2 * BRP}{f_{clk}}$$

Where: BRP (Baud Rate Pre-scaler) is the value stored in BCR0 incremented by 1 and fclk is the used peripheral bus frequency.

- BCR1 (Address = H'004)

|                |           |     |     |     |    |           |     |     |   |   |          |     |   |   |   |     |
|----------------|-----------|-----|-----|-----|----|-----------|-----|-----|---|---|----------|-----|---|---|---|-----|
| Bit:           | 15        | 14  | 13  | 12  | 11 | 10        | 9   | 8   | 7 | 6 | 5        | 4   | 3 | 2 | 1 | 0   |
|                | TSG1[3:0] |     |     |     | -  | TSG2[2:0] |     |     | - | - | SJW[1:0] |     | - | - | - | BSP |
| Initial value: | 0         | 0   | 0   | 0   | 0  | 0         | 0   | 0   | 0 | 0 | 0        | 0   | 0 | 0 | 0 | 0   |
| R/W:           | R/W       | R/W | R/W | R/W | R  | R/W       | R/W | R/W | R | R | R/W      | R/W | R | R | R | R/W |

**Bits 15 to 12 — Time Segment 1 (TSG1[3:0] = BCR1[15:12]):** These bits are used to set the segment TSEG1 (= PRSEG + PHSEG1) to compensate for edges on the CAN Bus with a positive phase error. A value from 4 to 16 time quanta can be set.

| Bit 15: | Bit 14: | Bit 13: | Bit 12: |             |
|---------|---------|---------|---------|-------------|
| TSG1[3] | TSG1[2] | TSG1[1] | TSG1[0] | Description |

|   |   |   |   |                                    |
|---|---|---|---|------------------------------------|
| 0 | 0 | 0 | 0 | Setting prohibited (Initial value) |
| 0 | 0 | 0 | 1 | Setting prohibited                 |
| 0 | 0 | 1 | 0 | Setting prohibited                 |
| 0 | 0 | 1 | 1 | PRSEG + PHSEG1 = 4 time quanta     |
| 0 | 1 | 0 | 0 | PRSEG + PHSEG1 = 5 time quanta     |
| : | : | : | : | :                                  |
| : | : | : | : | :                                  |
| 1 | 1 | 1 | 1 | PRSEG + PHSEG1 = 16 time quanta    |

**Bit 11 : Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 10 to 8 — Time Segment 2 (TSG2[2:0] = BCR1[10:8]):** These bits are used to set the segment TSEG2 (=PHSEG2) to compensate for edges on the CAN Bus with a negative phase error. A value from 2 to 8 time quanta can be set as shown below.

| Bit 10:<br>TSG2[2] | Bit 9:<br>TSG2[1] | Bit 8:<br>TSG2[0] | Description                                       |
|--------------------|-------------------|-------------------|---------------------------------------------------|
| 0                  | 0                 | 0                 | Setting prohibited (Initial value)                |
| 0                  | 0                 | 1                 | PHSEG2 = 2 time quanta (conditionally prohibited) |
| 0                  | 1                 | 0                 | PHSEG2 = 3 time quanta                            |
| 0                  | 1                 | 1                 | PHSEG2 = 4 time quanta                            |
| 1                  | 0                 | 0                 | PHSEG2 = 5 time quanta                            |
| 1                  | 0                 | 1                 | PHSEG2 = 6 time quanta                            |
| 1                  | 1                 | 0                 | PHSEG2 = 7 time quanta                            |
| 1                  | 1                 | 1                 | PHSEG2 = 8 time quanta                            |

**Bits 7 and 6 : Reserved.** The written value should always be '0' and the returned value is '0'.

**Bits 5 and 4 - ReSynchronisation Jump Width (SJW[1:0] = BCR0[5:4]):** These bits set the synchronisation jump width.

| Bit 5:<br>SJW[1] | Bit 4:<br>SJW[0] | Description                                                 |
|------------------|------------------|-------------------------------------------------------------|
| 0                | 0                | Synchronisation Jump width = 1 time quantum (Initial value) |
| 0                | 1                | Synchronisation Jump width = 2 time quanta                  |
| 1                | 0                | Synchronisation Jump width = 3 time quanta                  |
| 1                | 1                | Synchronisation Jump width = 4 time quanta                  |

**Bits 3 to 1 : Reserved.** The written value should always be '0' and the returned value is '0'.

**Bit 0 — Bit Sample Point (BSP = BCR1[0]):** Sets the point at which data is sampled.

| Bit 0 : BSP | Description                                                                         |
|-------------|-------------------------------------------------------------------------------------|
| 0           | Bit sampling at one point (end of time segment 1) (Initial value)                   |
| 1           | Bit sampling at three points (rising edge of the last three clock cycles of PHSEG1) |

- BCR0 (Address = H'006)

|                |    |    |    |    |    |    |   |   |          |     |     |     |     |     |     |     |

| 0                | 0                | 0                | 0                | 0                | 0                | 0                | 0                | 2 × peripheral bus clock<br>(Initial value)      |
| 0                | 0                | 0                | 0                | 0                | 0                | 0                | 1                | 4 × peripheral bus clock                         |
| 0                | 0                | 0                | 0                | 0                | 0                | 1                | 0                | 6 × peripheral bus clock                         |
| :                | :                | :                | :                | :                | :                | :                | :                | 2 × (register value+1) ×<br>peripheral bus clock |
| 0                | 1                | 1                | 1                | 1                | 1                | 1                | 1                | 512 × peripheral bus clock                       |

- Requirements of Bit Configuration Register

**SYNC\_SEG:** Segment for establishing synchronisation of nodes on the CAN bus. (Normal bit edge transitions occur in this segment.)

**PRSEG:** Segment for compensating for physical delay between networks.

**PHSEG1:** Buffer segment for correcting phase drift (positive). (This segment is extended when synchronisation or resynchronisation is established.)

**PHSEG2:** Buffer segment for correcting phase drift (negative). (This segment is shortened when synchronisation or resynchronisation is established.)

**TSEG1:** TSG1 + 1

TSEG2: TSG2 + 1

BRP: BRP[7:0] (bits 7 to 0 in BCR0)

The RCAN-ET Bit Rate Calculation is:

$$\text{Bit Rate} = \frac{f_{\text{clk}}}{2 * (\text{BRP} + 1) * (\text{TSEG1} + \text{TSEG2} + 1)}$$

where BRP is given by the register value, and TSEG1 and TSEG2 are derived values from TSG1 and TSG2 register values. The '+ 1' in the above formula is for the Sync-Seg which duration is 1 time quanta.

$f_{\text{CLK}}$  = Peripheral Clock

#### BCR Setting Constraints

$\text{TSEG1}_{\text{min}} > \text{TSEG2} \geq \text{SJW}_{\text{max}}$  (SJW = 1 to 4)

$8 \leq \text{TSEG1} + \text{TSEG2} + 1 \leq 25$  time quanta (TSEG1 + TSEG2 + 1 = 7 is not allowed)

$\text{TSEG2} \geq 2$

These constraints allow the setting range shown in the table below for TSEG1 and TSEG2 in the Bit Configuration Register. The number in the table shows possible setting of SJW. "No" shows that there is no allowed combination of TSEG1 and TSEG2.

|      |       | 001 | 010 | 011 | 100 | 101 | 110 | 111 | TSG2  |
|------|-------|-----|-----|-----|-----|-----|-----|-----|-------|
|      |       | 2   | 3   | 4   | 5   | 6   | 7   | 8   | TSEG2 |
| TSG1 | TSEG1 |     |     |     |     |     |     |     |       |
| 0011 | 4     | No  | 1-3 | No  | No  | No  | No  | No  |       |
| 0100 | 5     | 1-2 | 1-3 | 1-4 | No  | No  | No  | No  |       |
| 0101 | 6     | 1-2 | 1-3 | 1-4 | 1-4 | No  | No  | No  |       |
| 0110 | 7     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | No  | No  |       |
| 0111 | 8     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | No  |       |
| 1000 | 9     | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1001 | 10    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1010 | 11    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1011 | 12    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1100 | 13    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1101 | 14    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1110 | 15    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |
| 1111 | 16    | 1-2 | 1-3 | 1-4 | 1-4 | 1-4 | 1-4 | 1-4 |       |

Example 1: To have a Bit rate of 500 Kbps with a frequency of fclk = 40 MHz it is possible to set: BRP = 3, TSEG1 = 6, TSEG2 = 3.

Then the configuration to write is BCR1 = 5200 and BCR0 = 0003.

Example 2: To have a Bit rate of 250 Kps with a frequency of 35 MHz it is possible to set: BPR = 4, TSEG1 = 8, TSEG2 = 5.

Then the configuration to write is BCR1 = 7400 and BCR0 = 0004.

#### (4) Interrupt Request Register (IRR)

The interrupt register (IRR) is a 16-bit read/write-clearable register containing status flags for the various interrupt sources.

- IRR (Address = H'008)

| Bit:           | 15 | 14 | 13    | 12    | 11 | 10 | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|----------------|----|----|-------|-------|----|----|------|------|------|------|------|------|------|------|------|------|
|                | -  | -  | IRR13 | IRR12 | -  | -  | IRR9 | IRR8 | IRR7 | IRR6 | IRR5 | IRR4 | IRR3 | IRR2 | IRR1 | IRR0 |
| Initial value: | 0  | 0  | 0     | 0     | 0  | 0  | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 1    |
| R/W:           | R  | R  | R/W   | R/W   | R  | R  | R    | R    | R/W  | R/W  | R/W  | R/W  | R/W  | R/W  | R    | R/W  |

**Bits 15 to 14: Reserved.**

**Bit 13 - Message Error Interrupt (IRR13):** this interrupt indicates that:

- A message error has occurred when in test mode.
- Note: If a Message Overload condition occurs when in Test Mode, then this bit will not be set. When not in test mode this interrupt is inactive.

| Bit 13: IRR13 | Description                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------|
| 0             | message error has not occurred in test mode (Initial value)<br>[Clearing condition] Writing 1 |
| 1             | [Setting condition] message error has occurred in test mode                                   |

**Bit 12 – Bus activity while in sleep mode (IRR12):** IRR12 indicates that a CAN bus activity is present. While the RCAN-ET is in sleep mode and a dominant bit is detected on the CAN bus, this bit is set. This interrupt is cleared by writing a '1' to this bit position. Writing a '0' has no effect. If auto wakeup is not used and this interrupt is not requested it needs to be disabled by the related interrupt mask register. If auto wake up is not used and this interrupt is requested it should be cleared only after recovering from sleep mode. This is to avoid that a new falling edge of the reception line causes the interrupt to get set again.

Please note that the setting time of this interrupt is different from the clearing time of GSR4.

| Bit 12: IRR12 | Description                                                                         |
|---------------|-------------------------------------------------------------------------------------|
| 0             | bus idle state (Initial value)<br>[Clearing condition] Writing 1                    |
| 1             | [Setting condition] dominant bit level detection on the Rx line while in sleep mode |

## Bits 11 to 10: Reserved

**Bit 9 – Message Overrun/Overwrite Interrupt Flag (IRR9):** Flag indicating that a message has been received but the existing message in the matching Mailbox has not been read as the corresponding RXPR or RFPR is already set to '1' and not yet cleared by the CPU. The received message is either abandoned (overrun) or overwritten dependant upon the NMC (New Message Control) bit. This bit is cleared when all bit in UMSR (Unread Message Status Register) are cleared (by writing '1') or by setting MBIMR (MailBox interrupt Mast Register) for all UMSR flag set . It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

| Bit 9: IRR9 | Description                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | No pending notification of message overrun/overwrite<br>[Clearing condition] Clearing of all bit in UMSR/setting MBIMR for all UMSR set (initial value)                                             |
| 1           | A receive message has been discarded due to overrun condition or a message has been overwritten<br>[Setting condition] Message is received while the corresponding RXPR and/or RFPR =1 and MBIMR =0 |

**Bit 8 - Mailbox Empty Interrupt Flag (IRR8):** This bit is set when one of the messages set for transmission has been successfully sent (corresponding TXACK flag is set) or has been successfully aborted (corresponding ABACK flag is set). The related TXPR is also cleared and this mailbox is now ready to accept a new message data for the next transmission. In effect, this bit is set by an OR'ed signal of the TXACK and ABACK bits not masked by the corresponding MBIMR flag. Therefore, this bit is automatically cleared when all the TXACK and ABACK bits are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit position has no effect.

| Bit 8: IRR8 | Description                                                                                                                                                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | Messages set for transmission or transmission cancellation request NOT progressed. (Initial value)<br>[Clearing Condition] All the TXACK and ABACK bits are cleared/setting MBIMR for all TXACK and ABACK set                                                 |
| 1           | Message has been transmitted or aborted, and new message can be stored<br>[Setting condition]<br>When one of the TXPR bits is cleared by completion of transmission or completion of transmission abort, i.e., when a TXACK or ABACK bit is set (if MBIMR=0). |

**Bit 7 — Overload Frame (IRR7):** Flag indicating that the RCAN-ET has detected a condition that should initiate the transmission of an overload frame. Note that on the condition of transmission being prevented, such as listen only mode, an Overload Frame will NOT be transmitted, but IRR7 will still be set. IRR7 remains asserted until reset by writing a '1' to this bit position - writing a '0' has no effect.

| Bit 7: IRR7 | Description                                      |
|-------------|--------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)   |
| 1           | [Setting conditions] Overload condition detected |

**Bit 6 — Bus Off Interrupt Flag (IRR6):** This bit is set when RCAN-ET enters the Bus-off state or when RCAN-ET leaves Bus-off and returns to Error-Active. The cause therefore is the existing condition  $TEC \geq 256$  at the node or the end of the Bus-off recovery sequence (128X11 consecutive recessive bits) or the transition from Bus Off to Halt (automatic or manual). This bit remains set even if the RCAN-ET node leaves the bus-off condition, and needs to be explicitly cleared by S/W. The S/W is expected to read the GSR0 to judge whether RCAN-ET is in the bus-off or error active status. It is cleared by writing a '1' to this bit position even if the node is still bus-off. Writing a '0' has no effect.

| Bit 6: IRR6 | Description                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                                                                                                                                    |
| 1           | Enter Bus off state caused by transmit error or Error Active state returning from Bus-off<br>[Setting condition] When $TEC \geq 256$ or End of Bus-off after 128X11 consecutive recessive bits or transition from Bus Off to Halt |

**Bit 5 — Error Passive Interrupt Flag (IRR5):** Interrupt flag indicating the error passive state caused by the transmit or receive error counter or by Error Passive forced by test mode. This bit is reset by writing a '1' to this bit position, writing a '0' has no effect. If this bit is cleared the node may still be error passive. Please note that the SW needs to check GSR0 and GSR5 to judge whether RCAN-ET is in Error Passive or Bus Off status.

| Bit 5: IRR5 | Description                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                                                       |
| 1           | Error passive state caused by transmit/receive error<br>[Setting condition] When $TEC \geq 128$ or $REC \geq 128$ or Error Passive test mode is used |

**Bit 4 — Receive Error Counter Warning Interrupt Flag (IRR4):** This bit becomes set if the receive error counter (REC) reaches a value greater than 95 when RCAN-ET is not in the Bus Off status. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

| Bit 4: IRR4 | Description                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                                                      |
| 1           | Error warning state caused by receive error<br>[Setting condition] When $REC \geq 96$ and RCAN-ET is not in Bus Off |

**Bit 3 — Transmit Error Counter Warning Interrupt Flag (IRR3):** This bit becomes set if the transmit error counter (TEC) reaches a value greater than 95. The interrupt is reset by writing a '1' to this bit position, writing '0' has no effect.

| Bit 3: IRR3 | Description                                                                            |
|-------------|----------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1 (Initial value)                                         |
| 1           | Error warning state caused by transmit error<br>[Setting condition] When $TEC \geq 96$ |

**Bit 2 — Remote Frame Request Interrupt Flag (IRR2):** flag indicating that a remote frame has been received in a mailbox. This bit is set if at least one receive mailbox, with related MBIMR not set, contains a remote frame transmission request. This bit is automatically cleared when all bits in the Remote Frame Receive Pending Register (RFPR), are cleared. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

| Bit 2: IRR2 | Description                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Clearing of all bits in RFPR (Initial value)                                                           |
| 1           | at least one remote request is pending<br>[Setting condition] When remote frame is received and the corresponding MBIMR = 0 |

**Bit 1 — Data Frame Received Interrupt Flag (IRR1):** IRR1 indicates that there are pending Data Frames received. If this bit is set at least one receive mailbox contains a pending message. This bit is cleared when all bits in the Data Frame Receive Pending Register (RXPR) are cleared, i.e. there is no pending message in any receiving mailbox. It is in effect a logical OR of the RXPR flags from each configured receive mailbox with related MBIMR not set. It is also cleared by writing a '1' to all the correspondent bit position in MBIMR. Writing to this bit has no effect.

| Bit 1: IRR1 | Description                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Clearing of all bits in RXPR (Initial value)                                                      |
| 1           | Data frame received and stored in Mailbox<br>[Setting condition] When data is received and the corresponding MBIMR = 0 |

**Bit 0 — Reset/Halt/Sleep Interrupt Flag (IRR0):** This flag can get set for three different reasons. It can indicate that:

1. Reset mode has been entered after a SW (MCR0) or HW reset
2. Halt mode has been entered after a Halt request (MCR1)
3. Sleep mode has been entered after a sleep request (MCR5) has been made while in Halt mode.

The GSR may be read after this bit is set to determine which state RCAN-ET is in.

**Important :** When a Sleep mode request needs to be made, the Halt mode must be used beforehand. Please refer to the MCR5 description and figure 21.9.

IRR0 is set by the transition from "0" to "1" of GSR3 or GSR4 or by transition from Halt mode to Sleep mode. So, IRR0 is not set if RCAN-ET enters Halt mode again right after exiting from Halt mode, without GSR4 being cleared. Similarly, IRR0 is not set by direct transition from Sleep mode to Halt Request. At the transition from Halt/Sleep mode to Transition/Reception, clearing GSR4 needs (one-bit time - TSEG2) to (one-bit time \* 2 - TSEG2).

In the case of Reset mode, IRR0 is set, however, the interrupt to the CPU is not asserted since IMR0 is automatically set by initialisation.

| Bit 0: IRR0 | Description                                                                                                                                                                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0           | [Clearing condition] Writing 1                                                                                                                                                                                                                            |
| 1           | Transition to S/W reset mode or transition to halt mode or transition to sleep mode (Initial value)<br>[Setting condition] When reset/halt/sleep transition is completed after a reset (MCR0 or HW) or Halt mode (MCR1) or Sleep mode (MCR5) is requested |

## (5) Interrupt Mask Register (IMR)

The interrupt mask register is a 16 bit register that protects all corresponding interrupts in the Interrupt Request Register (IRR) from generating an output signal on the IRQ. An interrupt request is masked if the corresponding bit position is set to '1'. This register can be read or written at any time. The IMR directly controls the generation of IRQ, but does not prevent the setting of the corresponding bit in the IRR.

- IMR (Address = H'00A)

|                |       |       |       |       |       |       |      |      |      |      |      |      |      |      |      |      |
|----------------|-------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|
| Bit:           | 15    | 14    | 13    | 12    | 11    | 10    | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

**Bit 15 to 0:** Maskable interrupt sources corresponding to IRR[15:0] respectively. When a bit is set, the interrupt signal is not generated, although setting the corresponding IRR bit is still performed.

| Bit[15:0]: IMRn | Description                                                                 |
|-----------------|-----------------------------------------------------------------------------|
| 0               | Corresponding IRR is not masked (IRQ is generated for interrupt conditions) |
| 1               | Corresponding interrupt of IRR is masked (Initial value)                    |

## (6) Transmit Error Counter (TEC) and Receive Error Counter (REC)

The Transmit Error Counter (TEC) and Receive Error Counter (REC) is a 16-bit read/(write) register that functions as a counter indicating the number of transmit/receive message errors on the CAN Interface. The count value is stipulated in the CAN protocol specification Refs. [1], [2], [3] and [4]. When not in (Write Error Counter) test mode this register is read only, and can only be modified by the CAN Interface. This register can be cleared by a Reset request (MCR0) or entering to bus off.

In Write Error Counter test mode (i.e. TST[2:0] = 3'b100), it is possible to write to this register. The same value can only be written to TEC/REC, and the value written into TEC is set to TEC and REC. When writing to this register, RCAN-ET needs to be put into Halt Mode. This feature is only intended for test purposes.

- TEC/REC (Address = H'00C)

| Bit:           | 15        | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|----------------|-----------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
|                | TEC7      | TEC6 | TEC5 | TEC4 | TEC3 | TEC2 | TEC1 | TEC0 | REC7 | REC6 | REC5 | REC4 | REC3 | REC2 | REC1 | REC0 |
| Initial value: | 0         | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
|                | R/W: R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

Note: \* It is only possible to write the value in test mode when TST[2:0] in MCR is 3'b100.  
 REC is incremented during Bus Off to count the recurrences of 11 recessive bits as requested by the Bus Off recovery sequence.

### 21.3.4 RCAN-ET Mailbox Registers

The following sections describe RCAN-ET Mailbox registers that control / flag individual Mailboxes. The address is mapped as follows.

**Important :** LongWord access is carried out as two consecutive Word accesses.

| Description                       | Address | Name   | Access Size (bits) |
|-----------------------------------|---------|--------|--------------------|
| Transmit Pending 1                | H'020   | TXPR1  | LW                 |
| Transmit Pending 0                | H'022   | TXPR0  | —                  |
|                                   | H'024   |        |                    |
|                                   | H'026   |        |                    |
|                                   | H'028   |        |                    |
| Transmit Cancel 0                 | H'02A   | TXCR0  |                    |
|                                   | H'02C   |        |                    |
|                                   | H'02E   |        |                    |
|                                   | H'030   |        |                    |
| Transmit Acknowledge 0            | H'032   | TXACK0 | Word               |
|                                   | H'034   |        |                    |
|                                   | H'036   |        |                    |
|                                   | H'038   |        |                    |
| Abort Acknowledge 0               | H'03A   | ABACK0 | Word               |
|                                   | H'03C   |        |                    |
|                                   | H'03E   |        |                    |
|                                   | H'040   |        |                    |
| Data Frame Receive Pending 0      | H'042   | RXPR0  | Word               |
|                                   | H'044   |        |                    |
|                                   | H'046   |        |                    |
|                                   | H'048   |        |                    |
| Remote Frame Receive Pending 0    | H'04A   | RFPR0  | Word               |
|                                   | H'04C   |        |                    |
|                                   | H'04E   |        |                    |
|                                   | H'050   |        |                    |
| Mailbox Interrupt Mask Register 0 | H'052   | MBIMR0 | Word               |
|                                   | H'054   |        |                    |
|                                   | H'056   |        |                    |
|                                   | H'058   |        |                    |
| Unread message Status Register 0  | H'05A   | UMSR0  | Word               |
|                                   | H'05C   |        |                    |
|                                   | H'05E   |        |                    |

Figure 21.7 RCAN-ET Mailbox Registers

## (1) Transmit Pending Register (TXPR1, TXPR0)

The concatenation of TXPR1 and TXPR0 is a 32-bit register that contains any transmit pending flags for the CAN module. In the case of 16-bit bus interface, Long Word access is carried out as two consecutive word accesses.

### <Longword Write Operation>

### <Longword Read Operation>

The TXPR1 register cannot be modified and it is always fixed to '0'. The TXPR0 controls Mailbox-15 to Mailbox-1. The CPU may set the TXPR bits to affect any message being considered for transmission by writing a '1' to the corresponding bit location. Writing a '0' has no effect, and TXPR cannot be cleared by writing a '0' and must be cleared by setting the corresponding TXCR bits. TXPR may be read by the CPU to determine which, if any, transmissions are pending or in progress. In effect there is a transmit pending bit for all Mailboxes except for the Mailbox-0. Writing a '1' to a bit location when the mailbox is not configured to transmit is not allowed.

The RCAN-ET will clear a transmit pending flag after successful transmission of its corresponding message or when a transmission abort is requested successfully from the TXCR. The TXPR flag is not cleared if the message is not transmitted due to the CAN node losing the arbitration process or due to errors on the CAN bus, and RCAN-ET automatically tries to transmit it again unless its DART bit (Disable Automatic Re-Transmission) is set in the Message-Control of the corresponding Mailbox. In such case (DART set), the transmission is cleared and notified through Mailbox Empty Interrupt Flag (IRR8) and the correspondent bit within the Abort Acknowledgement Register (ABACK).

If the status of the TXPR changes, the RCAN-ET shall ensure that in the identifier priority scheme (MCR2=0), the highest priority message is always presented for transmission in an intelligent way even under circumstances such as bus arbitration losses or errors on the CAN bus. Please refer to section 21.4, Application Note.

When the RCAN-ET changes the state of any TXPR bit position to a '0', an empty slot interrupt (IRR8) may be generated. This indicates that either a successful or an aborted mailbox transmission has just been made. If a message transmission is successful it is signalled in the TXACK register, and if a message transmission abortion is successful it is signalled in the ABACK register. By checking these registers, the contents of the Message of the corresponding Mailbox may be modified to prepare for the next transmission.

- TXPR1

| Bit:           | 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
|----------------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
|                | TXPR1[15:0] |      |      |      |      |      |      |      |      |      |      |      |      |      |      |      |
| Initial value: | 0           | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    |
| R/W:           | R/W*        | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* |

Note : \* Any write operation is ignored.

Read value is always H'0000. Long word access is mandatory when reading or writing TXPR1/TXPR0. Writing any value to TXPR1 is allowed, however, write operation to TXPR1 has no effect.

- TXPR0

| Bit:           | 15          | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0 |
|----------------|-------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|---|
|                | TXPR0[15:1] |      |      |      |      |      |      |      |      |      |      |      |      |      |      | 0 |
| Initial value: | 0           | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0 |
| R/W:           | R/W*        | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | - |

Note : \* it is possible only to write a '1' for a Mailbox configured as transmitter.

**Bit 15 to 1** — indicates that the corresponding Mailbox is requested to transmit a CAN Frame. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively. When multiple bits are set, the order of the transmissions is governed by the MCR2 – CAN-ID or Mailbox number.

| Bit[15:1]:TXPR0 | Description                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | Transmit message idle state in corresponding mailbox (Initial value)<br>[Clearing Condition] Completion of message transmission or message transmission abortion (automatically cleared) |
| 1               | Transmission request made for corresponding mailbox                                                                                                                                      |

**Bit 0— Reserved:** This bit is always ‘0’ as this is a receive-only Mailbox. Writing a ‘1’ to this bit position has no effect. The returned value is ‘0’.

(2) Transmit Cancel Register (TXCR0)

TXCR0 is a 16-bit read / conditionally-write registers. The TXCR0 controls Mailbox-15 to Mailbox-1.This register is used by the CPU to request the pending transmission requests in the TXPR to be cancelled. To clear the corresponding bit in the TXPR the CPU must write a ‘1’ to the bit position in the TXCR. Writing a ‘0’ has no effect.

When an abort has succeeded the CAN controller clears the corresponding TXPR + TXCR bits, and sets the corresponding ABACK bit. However, once a Mailbox has started a transmission, it cannot be cancelled by this bit. In such a case, if the transmission finishes in success, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding TXACK bit, however, if the transmission fails due to a bus arbitration loss or an error on the bus, the CAN controller clears the corresponding TXPR + TXCR bit, and sets the corresponding ABACK bit. If an attempt is made by the CPU to clear a mailbox transmission that is not transmit-pending it has no effect. In this case the CPU will be not able at all to set the TXCR flag.

• TXCR0

Note : \* Only writing a ‘1’ to a Mailbox that is requested for transmission and is configured as transmit.

**Bit 15 to 1** — requests the corresponding Mailbox, that is in the queue for transmission, to cancel its transmission. The bit 15 to 1 corresponds to Mailbox-15 to 1 (and TXPR0[15:1]) respectively.

| Bit[15:1]:TXCR0 | Description                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | Transmit message cancellation idle state in corresponding mailbox (Initial value)<br>[Clearing Condition] Completion of transmit message cancellation (automatically cleared) |
| 1               | Transmission cancellation request made for corresponding mailbox                                                                                                              |

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

### (3) Transmit Acknowledge Register (TXACK0)

The TXACK0 is a 16-bit read / conditionally-write registers. This register is used to signal to the CPU that a mailbox transmission has been successfully made. When a transmission has succeeded the RCAN-ET sets the corresponding bit in the TXACK register. The CPU may clear a TXACK bit by writing a '1' to the corresponding bit location. Writing a '0' has no effect.

#### • TXACK0

|                |              |      |      |      |      |      |      |      |      |      |      |      |      |      |      |   |
|----------------|--------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|---|
| Bit:           | 15           | 14   | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0 |
|                | TXACK0[15:1] |      |      |      |      |      |      |      |      |      |      |      |      |      |      | 0 |
| Initial value: | 0            | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0    | 0 |
| R/W:           | R/W*         | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | R/W* | - |

Note : \* Only when writing a '1' to clear.

**Bit 15 to 1** — notifies that the requested transmission of the corresponding Mailbox has been finished successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

| Bit[15:1]:TXACK0 | Description                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing '1' (Initial value)                                                                                                                      |
| 1                | Corresponding Mailbox has successfully transmitted message (Data or Remote Frame)<br>[Setting Condition] Completion of message transmission for corresponding mailbox |

**Bit 0** — This bit is always '0' as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a '0'.

(4) Abort Acknowledge Register (ABACK0)

The ABACK0 is a 16-bit read / conditionally-write registers. This register is used to signal to the CPU that a mailbox transmission has been aborted as per its request. When an abort has succeeded the RCAN-ET sets the corresponding bit in the ABACK register. The CPU may clear the Abort Acknowledge bit by writing a '1' to the corresponding bit location. Writing a '0' has no effect. An ABACK bit position is set by the RCAN-ET to acknowledge that a TXPR bit has been cleared by the corresponding TXCR bit.

• ABACK0

Note : \* Only when writing a ‘1’ to clear.

**Bit 15 to 1** — notifies that the requested transmission cancellation of the corresponding Mailbox has been performed successfully. The bit 15 to 1 corresponds to Mailbox-15 to 1 respectively.

| Bit[15:1]:ABACK0 | Description                                                                                                                                                                 |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                                                                            |
| 1                | Corresponding Mailbox has cancelled transmission of message (Data or Remote Frame)<br>[Setting Condition] Completion of transmission cancellation for corresponding mailbox |

**Bit 0** — This bit is always ‘0’ as this is a receive-only mailbox. Writing a '1' to this bit position has no effect and always read back as a ‘0’.

(5)    **Data Frame Receive Pending Register (RXPR0)**

The RXPR0 is a 16-bit read / conditionally-write registers. The RXPR is a register that contains the received Data Frames pending flags associated with the configured Receive Mailboxes. When a CAN Data Frame is successfully stored in a receive mailbox the corresponding bit is set in the RXPR. The bit may be cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. However, the bit may only be set if the mailbox is configured by its MBC (Mailbox Configuration) to receive Data Frames. When a RXPR bit is set, it also sets IRR1 (Data Frame Received Interrupt Flag) if its MBIMR (Mailbox Interrupt Mask Register) is not set, and the interrupt signal is generated if IMR1 is not set. Please note that these bits are only set by receiving Data Frames and not by receiving Remote frames.

•    **RXPR0**

Note :   \*    Only when writing a ‘1’ to clear.

**Bit 15 to 0** — Configurable receive mailbox locations corresponding to each mailbox position from 15 to 0 respectively.

| Bit[15:0]: RXPR0 | Description                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                                 |
| 1                | Corresponding Mailbox received a CAN Data Frame<br>[Setting Condition] Completion of Data Frame receive on corresponding mailbox |

(6) Remote Frame Receive Pending Register (RFPR0)

The RFPR0 is a 16-bit read/conditionally-write registers. The RFPR is a register that contains the received Remote Frame pending flags associated with the configured Receive Mailboxes. When a CAN Remote Frame is successfully stored in a receive mailbox the corresponding bit is set in the RFPR. The bit may be cleared by writing a '1' to the corresponding bit position. Writing a '0' has no effect. In effect there is a bit position for all mailboxes. However, the bit may only be set if the mailbox is configured by its MBC (Mailbox Configuration) to receive Remote Frames. When a RFPR bit is set, it also sets IRR2 (Remote Frame Request Interrupt Flag) if its MBIMR (Mailbox Interrupt Mask Register) is not set, and the interrupt signal is generated if IMR2 is not set. Please note that these bits are only set by receiving Remote Frames and not by receiving Data frames.

• RFPR0

Note : \* Only when writing a ‘1’ to clear.

**Bit 15 to 0** — Remote Request pending flags for mailboxes 15 to 0 respectively.

| Bit[15:0]: RFPR0 | Description                                                                                                                    |
|------------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (Initial value)                                                                               |
| 1                | Corresponding Mailbox received Remote Frame<br>[Setting Condition] Completion of remote frame receive in corresponding mailbox |

(7)    Mailbox Interrupt Mask Register (MBIMR)

The MBIMR1 and MBIMR0 are 16-bit read/write registers. The MBIMR only prevents the setting of IRR related to the Mailbox activities, that are IRR[1] – Data Frame Received Interrupt, IRR[2] – Remote Frame Request Interrupt, IRR[8] – Mailbox Empty Interrupt, and IRR[9] – Message OverRun/OverWrite Interrupt. If a mailbox is configured as receive, a mask at the corresponding bit position prevents the generation of a receive interrupt (IRR[1] and IRR[2] and IRR[9]) but does not prevent the setting of the corresponding bit in the RXPR or RFPR or UMSR. Similarly when a mailbox has been configured for transmission, a mask prevents the generation of an Interrupt signal and setting of an Mailbox Empty Interrupt due to successful transmission or abortion of transmission (IRR[8]), however, it does not prevent the RCAN-ET from clearing the corresponding TXPR/TXCR bit + setting the TXACK bit for successful transmission, and it does not prevent the RCAN-ET from clearing the corresponding TXPR/TXCR bit + setting the ABACK bit for abortion of the transmission.

A mask is set by writing a '1' to the corresponding bit position for the mailbox activity to be masked. At reset all mailbox interrupts are masked.

•    MBIMR0

Bit 15 to 0 — Enable or disable interrupt requests from individual Mailbox-15 to Mailbox-0 respectively.

| Bit[15:0]: MBIMR0 | Description                                                         |
|-------------------|---------------------------------------------------------------------|
| 0                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 enabled                  |
| 1                 | Interrupt Request from IRR1/IRR2/IRR8/IRR9 disabled (initial value) |

(8) Unread Message Status Register (UMSR)

This register is a 16-bit read/conditionally write register and it records the mailboxes whose contents have not been accessed by the CPU prior to a new message being received. If the CPU has not cleared the corresponding bit in the RXPR or RFPR when a new message for that mailbox is received, the corresponding UMSR bit is set to ‘1’. This bit may be cleared by writing a ‘1’ to the corresponding bit location in the UMSR. Writing a ‘0’ has no effect.

If a mailbox is configured as transmit box, the corresponding UMSR will not be set.

• UMSR0

Bit 15 to 0 — Indicate that an unread received message has been overwritten or overrun condition has occurred for Mailboxes 15 to 0.

| Bit[15:0]: UMSR0 | Description                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                | [Clearing Condition] Writing ‘1’ (initial value)                                                                                                                  |
| 1                | Unread received message is overwritten by a new message or overrun condition<br>[Setting Condition] When a new message is received before RXPR or RFPR is cleared |

## 21.4 Application Note

### 21.4.1 Test Mode Settings

The RCAN-ET has various test modes. The register TST[2:0] (MCR[10:8]) is used to select the RCAN-ET test mode. The default (initialised) settings allow RCAN-ET to operate in Normal mode. The following table is examples for test modes.

Test Mode can be selected only while in configuration mode. The user must then exit the configuration mode (ensuring BCR0/BCR1 is set) in order to run the selected test mode.

| Bit10:<br>TST2 | Bit9:<br>TST1 | Bit8:<br>TST0 | Description                          |
|----------------|---------------|---------------|--------------------------------------|
| 0              | 0             | 0             | Normal Mode (initial value)          |
| 0              | 0             | 1             | Listen-Only Mode (Receive-Only Mode) |
| 0              | 1             | 0             | Self Test Mode 1 (External)          |
| 0              | 1             | 1             | Self Test Mode 2 (Internal)          |
| 1              | 0             | 0             | Write Error Counter                  |
| 1              | 0             | 1             | Error Passive Mode                   |
| 1              | 1             | 0             | Setting prohibited                   |
| 1              | 1             | 1             | Setting prohibited                   |

**Normal Mode:** RCAN-ET operates in the normal mode.

**Listen-Only Mode:** ISO-11898 requires this mode for baud rate detection. The Error Counters are cleared and disabled so that the TEC/REC does not increase the values, and the Tx Output is disabled so that RCAN-ET does not generate error frames or acknowledgment bits. IRR13 is set when a message error occurs.

**Self Test Mode 1:** RCAN-ET generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The Rx/Tx pins must be connected to the CAN bus.

**Self Test Mode 2:** RCAN-ET generates its own Acknowledge bit, and can store its own messages into a reception mailbox (if required). The Rx/Tx pins do not need to be connected to the CAN bus or any external devices, as the internal Tx is looped back to the internal Rx. Tx pin outputs only recessive bits and Rx pin is disabled.

**Write Error Counter:** TEC/REC can be written in this mode. RCAN-ET can be forced to become an Error Passive mode by writing a value greater than 127 into the Error Counters. The value written into TEC is used to write into REC, so only the same value can be set to these registers. Similarly, RCAN-ET can be forced to become an Error Warning by writing a value greater than 95 into them.

RCAN-ET needs to be in Halt Mode when writing into TEC/REC (MCR1 must be "1" when writing to the Error Counter). Furthermore this test mode needs to be exited prior to leaving Halt mode. Error Passive Mode: RCAN-ET can be forced to enter Error Passive mode.

Note: the REC will not be modified by implementing this Mode. However, once running in Error Passive Mode, the REC will increase normally should errors be received. In this Mode, RCAN-ET will enter BusOff if TEC reaches 256 (Dec). However when this mode is used RCAN-ET will not be able to become Error Active. Consequently, at the end of the Bus Off recovery sequence, RCAN-ET will move to Error Passive and not to Error Active

When message error occurs, IRR13 is set in all test modes.

## 21.4.2 Configuration of RCAN-ET

RCAN-ET is considered in configuration mode or after a H/W (Power On Reset)/ S/W (MCR[0]) reset or when in Halt mode. In both conditions RCAN-ET cannot join the CAN Bus activity and configuration changes have no impact on the traffic on the CAN Bus.

- After a Reset request  
The following sequence must be implemented to configure the RCAN-ET after (S/W or H/W) reset. After reset, all the registers are initialised, therefore, RCAN-ET needs to be configured before joining the CAN bus activity. Please read the notes carefully.

**Figure 21.8 Reset Sequence**

- Halt mode

When RCAN-ET is in Halt mode, it cannot take part to the CAN bus activity. Consequently the user can modify all the requested registers without influencing existing traffic on the CAN Bus. It is important for this that the user waits for the RCAN-ET to be in halt mode before to modify the requested registers - note that the transition to Halt Mode is not always immediate (transition will occurs when the CAN Bus is idle or in intermission). After RCAN-ET transit to Halt Mode, GSR4 is set.

Once the configuration is completed the Halt request needs to be released. RCAN-ET will join CAN Bus activity after the detection of 11 recessive bits on the CAN Bus.

- Sleep mode

When RCAN-ET is in sleep mode the clock for the main blocks of the IP is stopped in order to reduce power consumption. Only the following user registers are clocked and can be accessed: MCR, GSR, IRR and IMR. Interrupt related to transmission (TXACK and ABACK) and reception (RXPR and RFPR) cannot be cleared when in sleep mode (as TXACK, ABACK, RXPR and RFPR are not accessible) and must to be cleared beforehand.

The following diagram shows the flow to follow to move RCAN-ET into sleep mode.

Figure 21.9 - Halt Mode / Sleep Mode shows allowed state transition.

- Please don't set MCR5 (Sleep Mode) without entering Halt Mode.
- After MCR1 is set, please don't clear it before GSR4 is set and RCAN-ET enters Halt Mode.

**Figure 21.9 Halt Mode / Sleep Mode**

- Notes:
1. MCR5 can be cleared by automatically by detecting a dominant bit on the CAN Bus if MCR7 is set or by writing "0"
  2. MCR1 is cleared in SW. Clearing MCR1 and setting MCR5 have to be carried out by the same instruction.
  3. MCR1 must not be cleared in SW, before GSR4 is set. MCR1 can be set automatically in HW when RCAN-ET moves to Bus Off and MCR14 and MCR6 are both set.
  4. When MCR5 is cleared and MCR1 is set at the same time, RCAN-ET moves to Halt Request. Right after that, it moves to Halt Mode with no reception/transmission.

The following table shows conditions to access registers.

| RCAN-ET Registers                         |            |            |                  |       |               |                                    |                   |                                    |  |
|-------------------------------------------|------------|------------|------------------|-------|---------------|------------------------------------|-------------------|------------------------------------|--|
| Status Mode                               | MCR<br>GSR | IRR<br>IMR | BCR              | MBIMR | Flag_register | mailbox<br>(ctrl0, LAFM)           | mailbox<br>(data) | mailbox<br>(ctrl1)                 |  |
| Reset                                     | yes        | yes        | yes              | yes   | yes           | yes                                | yes               | yes                                |  |
| Transmission<br>Reception<br>Halt Request | yes        | yes        | no* <sup>1</sup> | yes   | yes           | no* <sup>1</sup> yes* <sup>2</sup> | yes* <sup>2</sup> | no* <sup>1</sup> yes* <sup>2</sup> |  |
| Halt                                      | yes        | yes        | no* <sup>1</sup> | yes   | yes           | yes                                | yes               | yes                                |  |
| Sleep                                     | yes        | yes        | no               | no    | no            | no                                 | no                | no                                 |  |

Notes: 1. No hardware protection  
2. When TXPR is not set.

### 21.4.3 Message Transmission Sequence

- Message Transmission Request

The following sequence is an example to transmit a CAN frame onto the bus. As described in the previous register section, please note that IRR8 is set when one of the TXACK or ABACK bits is set, meaning one of the Mailboxes has completed its transmission or transmission abortion and is now ready to be updated for the next transmission, whereas, the GSR2 means that there is currently no transmission request made (No TXPR flags set).

Figure 21.10 Transmission Request

- Internal Arbitration for transmission

The following diagram explains how RCAN-ET manages to schedule transmission-requested messages in the correct order based on the CAN identifier. 'Internal arbitration' picks up the highest priority message amongst transmit-requested messages.

**Figure 21.11 Internal Arbitration for Transmission**

The RCAN-ET has two state machines. One is for transmission, and the other is for reception.

- 1-1: When a TXPR bit(s) is set while the CAN bus is idle, the internal arbitration starts running immediately and the transmission is started.
- 1-2: Operations for both transmission and reception starts at SOF. Since there is no reception frame, RCAN-ET becomes transmitter.
- 2-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 2-2: Operations for both transmission and reception starts at SOF. Because of a reception frame with higher priority, RCAN-ET becomes receiver. Therefore, Reception is carried out instead of transmitting Frame-3.
- 3-1: At crc delimiter, internal arbitration to search next message transmitted starts.
- 3-2: Operations for both transmission and reception starts at SOF. Since a transmission frame has higher priority than reception one, RCAN-ET becomes transmitter.

Internal arbitration for the next transmission is also performed at the beginning of each error delimiter in case of an error is detected on the CAN Bus. It is also performed at the beginning of error delimiters following overload frame.

As the arbitration for transmission is performed at CRC delimiter, in case a remote frame request is received into a Mailbox with ATX=1 the answer can join the arbitration for transmission only at the following Bus Idle, CRC delimiter or Error Delimiter.

Depending on the status of the CAN bus, following the assertion of the TXCR, the corresponding Message abortion can be handled with a delay of maximum 1 CAN Frame.

## 21.4.4 Message Receive Sequence

The diagram below shows the message receive sequence.

**Figure 21.12 Message Receive Sequence**

When RCAN-ET recognises the end of the Arbitration field while receiving a message, it starts comparing the received identifier to the identifiers set in the Mailboxes, starting from Mailbox-15 down to Mailbox-0. It first checks the MBC if it is configured as a receive box, and reads LAFM, and reads the CAN-ID of Mailbox-15 (if configured as receive) to finally compare them to the received ID. If it does not match, the same check takes place at Mailbox-14 (if configured as receive). Once RCAN-ET finds a matching identifier, it stores the number of Mailbox-[N] into an internal buffer, stops the search, and goes back to idle state, waiting for the EndOfFrame (EOF) to come. When the 6<sup>th</sup> bit of EOF is notified by the CAN Interface logic, the received message is written or abandoned, depending on the NMC bit. No modification of configuration during communication is allowed. Entering Halt Mode is one of ways to modify configuration. If it is written into the corresponding Mailbox, including the CAN-ID, i.e., there is a possibility that the CAN-ID is overwritten by a different CAN-ID of the received message due to the LAFM used. This also implies that, if the identifier of a received message matches to ID + LAFM of 2 or more Mailboxes, the higher numbered Mailbox will always store the relevant messages and the lower numbered Mailbox will never receive messages. Therefore, the settings of the identifiers and LAFMs need to be carefully selected.

With regards to the reception of data and remote frames described in the above flow diagram the clearing of the UMSR flag after the reading of IRR is to detect situations where a message is overwritten by a new incoming message stored in the same mailbox while the interrupt service routine is running. If during the final check of UMSR a overwrite condition is detected the message needs to be discarded and read again.

In case UMSR is set and the Mailbox is configured for overrun (NMC = 0) the message is still valid, however it is obsolete as it is not reflecting the latest message monitored on the CAN Bus. Please access the full Mailbox content before clearing the related RXPR/RFPR flag.

Please note that in the case a received remote frame is overwritten by a data frame, both the remote frame request interrupt (IRR2) and data frame received interrupt (IRR1) and also the Receive Flags (RXPR and RFPR) are set. In an analogous way, the overwriting of a data frame by a remote frame, leads to setting both IRR2 and IRR1.

In the Overrun Mode (NMC = '0'), only the first Mailbox will cause the flags to be asserted. So, if a Data Frame is initially received, then RXPR and IRR1 are both asserted. If a Remote Frame is then received before the Data Frame has been read, then RFPR and IRR2 are NOT set. In this case UMSR of the corresponding Mailbox will still be set.

### 21.4.5 Reconfiguration of Mailbox

When re-configuration of Mailboxes is required, the following procedures should be taken.

- Change configuration of transmit box

Two cases are possible.

- Change of ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART

This change is possible only when MBC=3'b000. Confirm that the corresponding TXPR is not set. The configuration (except MBC bit) can be changed at any time.

- Change from transmit to receive configuration (MBC)

Confirm that the corresponding TXPR is not set. The configuration can be changed only in Halt or reset state. Please note that it might take longer for RCAN-ET to transit to halt state if it is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-ET will not be able to receive/transmit messages during the Halt state.

In case RCAN-ET is in the Bus Off state the transition to halt state depends on the configuration of the bit 6 of MCR and also bit and 14 of MCR.

- Change configuration (ID, RTR, IDE, LAFM, Data, DLC, NMC, ATX, DART, MBC) of receiver box or Change receiver box to transmitter box

The configuration can be changed only in Halt Mode.

RCAN-ET will not lose a message if the message is currently on the CAN bus and RCAN-ET is a receiver. RCAN-ET will be moving into Halt Mode after completing the current reception. Please note that it might take longer if RCAN-ET is receiving or transmitting a message (as the transition to the halt state is delayed until the end of the reception/transmission), and also RCAN-ET will not be able to receive/transmit messages during the Halt Mode.

In case RCAN-ET is in the Bus Off state the transition to halt mode depends on the configuration of the bit 6 and 14 of MCR.

**Figure 21.13 Change ID of Receive Box or Change Receive Box to Transmit Box**

## 21.5 Interrupt Sources

Table 21.2 lists the RCAN-ET interrupt sources. With the exception of the reset processing interrupt (IRR0) by a power-on reset, these sources can be masked. Masking is implemented using the mailbox interrupt mask register 0 (MBIMR0) and interrupt mask register (IMR). For details on the interrupt vector of each interrupt source, see section 6, Interrupt Controller (INTC).

**Table 21.2 RCAN-ET Interrupt Sources**

| Module  | Interrupt           | Description                                             | Interrupt Flag      | DTC Activation         |
|---------|---------------------|---------------------------------------------------------|---------------------|------------------------|
| RCAN-ET | ERS_0               | Error Passive Mode ( $TEC \geq 128$ or $REC \geq 128$ ) | IRR5                | Not possible           |
|         |                     | Bus Off ( $TEC \geq 256$ )/Bus Off recovery             | IRR6                |                        |
|         |                     | Error warning ( $TEC \geq 96$ )                         | IRR3                |                        |
|         |                     | Error warning ( $REC \geq 96$ )                         | IRR4                |                        |

Notes: 1. Available only in Test Mode.

2. RM0\_0 is an interrupt generated by the remote request pending flag for mailbox 0 (RFPR0[0]) or the data frame receive flag for mailbox 0 (RXPR0[0]). RM1\_0 is an interrupt generated by the remote request pending flag for mailbox n (RFPR0[n]) or the data frame receive flag for mailbox n (RXPR0[n]) ( $n = 1$  to 15).
3. IRR1 is a data frame received interrupt flag for mailboxes 0 to 15, and IRR2 is a remote frame request interrupt flag for mailboxes 0 to 15.
4. The DTC can be activated only by the RM0\_0 interrupt.

## 21.6 DTC Interface

The DTC can be activated by the reception of a message in RCAN-ET mailbox 0. When DTC transfer ends after DTC activation has been set, flags of RXPR0 and RFPR0 are cleared automatically. An interrupt request due to a receive interrupt from the RCAN-ET cannot be sent to the CPU in this case. Figure 21.14 shows a DTC transfer flowchart.

**Figure 21.14 DTC Transfer Flowchart**

## 21.7 DMAC Interface

The DMAC can be activated by the reception of a message in RCAN-ET mailbox 0. When DMAC transfer ends after DMAC activation has been set, flags of RXPR0 and RFPR0 are cleared automatically. An interrupt request due to a receive interrupt from the RCAN-ET cannot be sent to the CPU in this case. Figure 21.15 shows a DMAC transfer flowchart.

**21.15 DMAC Transfer Flowchart**

## 21.8 CAN Bus Interface

A bus transceiver IC is necessary to connect this LSI to a CAN bus. A Renesas HA13721 transceiver IC and its compatible products are recommended. The specification for this LSI circuit is a 3-V power-supply voltage, so use a level-shifter IC between its CRx0 pin and the Rxd pin of the HA13721. Figure 21.16 shows a sample connection diagram.

**Figure 21.16 High-Speed CAN Interface Using HA13721**

## 21.9 Usage Notes

### 21.9.1 Module Standby Mode

The clock supply to RCAN-ET can be stopped or started by using the standby control register 6 (STBCR6). With the initial value, the clock supply is stopped. Access to the RCAN-ET registers should be made only after releasing RCAN-ET from module standby mode.

### 21.9.2 Reset

RCAN-ET can be reset by hardware reset or software reset.

- **Hardware reset**  
RCAN-ET is reset to the initial state by power-on reset or on entering module standby mode.
- **Software reset**  
By setting the MCR0 bit in Master Control Register (MCR), RCAN-ET registers, excluding the MCR0 bit, and the CAN communication circuitry are initialized.

Since the IRR0 bit in Interrupt Request Register (IRR) is set by the initialization upon reset, it should be cleared while RCAN-ET is in configuration mode during the reset sequence.

The areas except for message control field 1 (CONTROL1) of mailboxes are not initialized by reset because they are in RAM. After power-on reset, all mailboxes should be initialized while RCAN-ET is in configuration mode during the reset sequence.

### 21.9.3 CAN Sleep Mode

In CAN sleep mode, the clock supply to the major parts in the module is stopped. Therefore, do not make access in CAN sleep mode except for access to the MCR, GSR, IRR, and IMR registers.

### 21.9.4 Register Access

If the mailbox area is accessed while the CAN communication circuitry in RCAN-ET is storing a received CAN bus frame in a mailbox, a 0 to five peripheral clock cycles of wait state is generated.

### 21.9.5 Interrupts

As shown in table 21.2, a Mailbox 0 receive interrupt can activate the DTC. If configured such that the DTC is activated by a Mailbox 0 receive interrupt and clearing of the interrupt source flag upon DTC transfer is enabled, use block transfer mode and read the whole Mailbox 0 message up to the message control field 1 (CONTROL1).

## Section 22 Pin Function Controller (PFC)

The pin function controller (PFC) is composed of registers that are used to select the functions of multiplexed pins and assign pins to be inputs or outputs. Tables 22.1 to 22.6 list the multiplexed pins of this LSI.

**Table 22.1 Multiplexed Pins (Port A)**

| Port | Function 1<br>(Related<br>Module) | Function 2<br>(Related<br>Module)                  | Function 3<br>(Related<br>Module) | Function 4<br>(Related<br>Module) | Function 5<br>(Related<br>Module) | Function 6<br>(Related<br>Module) | Function 7<br>(Related<br>Module) | Function 8<br>(Related<br>Module)  |

- Notes: 1. This function is enabled in only on-chip ROM enabled/disabled external extension mode. Do not set it in single-chip mode.
2. A pin function is analog input during sampling by the A/D converter, and general input during a period other than this sampling.

## 22.1 Register Descriptions

The PFC has the following registers. See section 32, List of Registers for register addresses and register states in each operating mode.

**Table 22.8 Register Configuration**

| Register Name                         | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------------------------------------|--------------|-----|---------------|------------|-------------|
| Port A I/O register H                 | PAIORH       | R/W | H'0000        | H'FFFE3804 | 8, 16, 32   |
| Port A I/O register L                 | PAIORL       | R/W | H'0000        | H'FFFE3806 | 8, 16       |
| Port A control register H2            | PACRH2       | R/W | H'0000        | H'FFFE380C | 8, 16, 32   |
| Port A control register H1            | PACRH1       | R/W | H'0000*       | H'FFFE380E | 8, 16       |
| Port A control register L4            | PACRL4       | R/W | H'0000*       | H'FFFE3810 | 8, 16, 32   |
| Port A control register L3            | PACRL3       | R/W | H'0000        | H'FFFE3812 | 8, 16       |
| Port A control register L2            | PACRL2       | R/W | H'0000        | H'FFFE3814 | 8, 16, 32   |
| Port A control register L1            | PACRL1       | R/W | H'0000        | H'FFFE3816 | 8, 16       |
| Port A pull-up MOS control register H | PAPCRH       | R/W | H'0000        | H'FFFE3828 | 8, 16, 32   |
| Port A pull-up MOS control register L | PAPCRL       | R/W | H'0000        | H'FFFE382A | 8, 16       |
| Port B I/O register L                 | PBIORL       | R/W | H'0000        | H'FFFE3886 | 8, 16       |
| Port B control register L4            | PBCRL4       | R/W | H'0000        | H'FFFE3890 | 8, 16, 32   |
| Port B control register L3            | PBCRL3       | R/W | H'0000*       | H'FFFE3892 | 8, 16       |
| Port B control register L2            | PBCRL2       | R/W | H'0000*       | H'FFFE3894 | 8, 16, 32   |
| Port B control register L1            | PBCRL1       | R/W | H'0000*       | H'FFFE3896 | 8, 16       |
| Port B pull-up MOS control register L | PBPCRL       | R/W | H'0000        | H'FFFE38AA | 8, 16       |
| Port C I/O register L                 | PCIORL       | R/W | H'0000        | H'FFFE3906 | 8, 16       |
| Port C control register L4            | PCCRL4       | R/W | H'0000*       | H'FFFE3910 | 8, 16, 32   |
| Port C control register L3            | PCCRL3       | R/W | H'0000*       | H'FFFE3912 | 8, 16       |
| Port C control register L2            | PCCRL2       | R/W | H'0000*       | H'FFFE3914 | 8, 16, 32   |
| Port C control register L1            | PCCRL1       | R/W | H'0000*       | H'FFFE3916 | 8, 16       |
| Port C pull-up MOS control register L | PCPCRL       | R/W | H'0000        | H'FFFE392A | 8, 16       |
| Port D I/O register H                 | PDIORH       | R/W | H'0000        | H'FFFE3984 | 8, 16, 32   |
| Port D I/O register L                 | PDIORL       | R/W | H'0000        | H'FFFE3986 | 8, 16       |
| Port D control register H4            | PDCRH4       | R/W | H'0000*       | H'FFFE3988 | 8, 16, 32   |
| Port D control register H3            | PDCRH3       | R/W | H'0000*       | H'FFFE398A | 8, 16       |
| Port D control register H2            | PDCRH2       | R/W | H'0000*       | H'FFFE398C | 8, 16, 32   |

| Register Name                         | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------------------------------------|--------------|-----|---------------|------------|-------------|
| Port D control register H1            | PDCRH1       | R/W | H'0000*       | H'FFFE398E | 8, 16       |
| Port D control register L4            | PDCRL4       | R/W | H'0000*       | H'FFFE3990 | 8, 16, 32   |
| Port D control register L3            | PDCRL3       | R/W | H'0000*       | H'FFFE3992 | 8, 16       |
| Port D control register L2            | PDCRL2       | R/W | H'0000*       | H'FFFE3994 | 8, 16, 32   |
| Port D control register L1            | PDCRL1       | R/W | H'0000*       | H'FFFE3996 | 8, 16       |
| Port D pull-up MOS control register H | PDPCRH       | R/W | H'0000        | H'FFFE39A8 | 8, 16, 32   |
| Port D pull-up MOS control register L | PDPCRL       | R/W | H'0000        | H'FFFE39AA | 8, 16       |
| Port E I/O register L                 | PEIORL       | R/W | H'0000        | H'FFFE3A06 | 8, 16       |
| Port E control register L4            | PECRL4       | R/W | H'0000        | H'FFFE3A10 | 8, 16, 32   |
| Port E control register L3            | PECRL3       | R/W | H'0000        | H'FFFE3A12 | 8, 16       |
| Port E control register L2            | PECRL2       | R/W | H'0000        | H'FFFE3A14 | 8, 16, 32   |
| Port E control register L1            | PECRL1       | R/W | H'0000        | H'FFFE3A16 | 8, 16       |
| Large current port control register   | HCPCR        | R/W | H'000F        | H'FFFE3A20 | 8, 16, 32   |
| IRQOUT function control register      | IFCR         | R/W | H'0000        | H'FFFE3A22 | 8, 16       |
| Port E pull-up MOS control register L | PEPCRL       | R/W | H'0000        | H'FFFE3A2A | 8, 16       |
| DACK output timing control register   | PDACKCR      | R/W | H'0000        | H'FFFE3A2C | 8, 16       |

Note: \* The initial values of registers in each product vary according to the setting of the operating mode. See the description of each register in this section for details.

### 22.1.1 Port A I/O Registers H and L (PAIORH and PAIORL)

PAIORH and PAIORL are 16-bit readable/writable registers that are used to set the pins on port A as inputs or outputs. Bits PA21IOR to PA01IOR correspond to pins PA21 to PA0 (multiplexed port pin names except for the port names are abbreviated here). PAIORH and PAIORL are enabled when the port A pins are functioning as general-purpose inputs/outputs (PA21 to PA16 for PAIORH and PA15 to PA0 for PAIORL). In other states, they are disabled. A given pin on port A will be an output pin if the corresponding bit in PAIORH or PAIORL is set to 1, and an input pin if the bit is cleared to 0. Bits 15 to 6 of PAIORH are reserved. These bits are always read as 0. The write value should always be 0.

The initial values of PAIORL and PAIORH are both H'0000.

- Port A I/O Register H (PAIORH)

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5        | 4        | 3        | 2        | 1        | 0        |
|----------------|----|----|----|----|----|----|---|---|---|---|----------|----------|----------|----------|----------|----------|
|                | -  | -  | -  | -  | -  | -  | - | - | - | - | PA21 IOR | PA20 IOR | PA19 IOR | PA18 IOR | PA17 IOR | PA16 IOR |

## 22.1.2 Port A Control Registers H1 and H2, and L1 to L4 (PACRH1 and PACRH2, and PACRL1 to PACRL4)

PACRH1 and PACRH2, and PACRL1 to PACRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port A.

- Port A Control Register H2 (PACRH2)

### 22.1.4 Port B I/O Register L (PBIORL)

PBIORL is a 16-bit readable/writable register that is used to set the pins on port B as inputs or outputs. Bits PB15IOR to PB0IOR correspond to pins PB15 to PB0, respectively (multiplexed port pin names except for the port names are abbreviated here). PBIORL is enabled when the port B pins are functioning as general-purpose inputs/outputs (PB15 to PB0 for PBIORL) or TIOC input/output for the MTU2. In other states, PBIORL is disabled. A given pin on port B will be an output pin if the corresponding bit in PBIORL is set to 1, and an input pin if the bit is cleared to 0. However, settings for bits 13 and 12 in PBIORL are invalid.

The initial value of PBIORL is H'0000.

### 22.1.5 Port B Control Registers L1 to L4 (PBCRL1 to PBCRL4)

PBCRL1 to PBCRL4 are 16-bit readable/writable registers that are used to select the function of the multiplexed pins on port B.

Notes: 1. The initial value is 001 during the on-chip ROM disabled external extension mode.  
 2. Setting of the IRQOUT function control register (IFCR) selects  $\overline{\text{IRQOUT}}$  (INTC) or  $\overline{\text{REFOUT}}$  (BSC).

## 22.1.6 Port B Pull-Up MOS Control Register L (PBPCRL)

PBPCRL controls on/off of the input pull-up MOS of port B in bits.

- Port B Pull-Up MOS Control Register L (PBPCRL)

## 22.1.7 Port C I/O Register L (PCIORL)

PCIORL is a 16-bit readable/writable register that is used to set the pins on port C as inputs or outputs. Bits PC15IOR to PC0IOR correspond to pins PC15 to PC0, respectively (multiplexed port pin names except for the port names are abbreviated here). PCIORL is enabled when the port C pins are functioning as general-purpose inputs/outputs (PC15 to PC0). In other states, PCIORL is disabled. A given pin on port C will be an output pin if the corresponding bit in PCIORL is set to 1, and an input pin if the bit is cleared to 0. The initial value of PCIORL is H'0000.

## 22.1.8 Port C Control Registers L1 to L4 (PCCRL1 to PCCRL4)

PCCRL1 to PACRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port C.

- Port C Control Register L4 (PCCRL4)

## 22.1.9 Port C Pull-Up MOS Control Register L (PCPCRL)

PCPCRL controls on/off of the input pull-up MOS of port C in bits.

### • Port C Pull-Up MOS Control Register L (PCPCRL)

### 22.1.10 Port D I/O Registers H and L (PDIORH and PDIORL)

PDIORH and PDIORL are 16-bit readable/writable registers that are used to set the pins on port D as inputs or outputs. Bits PD31IOR to PD0IOR correspond to pins PD31 to PD0, respectively (multiplexed port pin names except for the port names are abbreviated here). PDIORL is enabled when the port D pins are functioning as general-purpose inputs/outputs (PD15 to PD0 for PDIORL) and TIOC inputs/outputs in MTU2S. In other states, PDIORL is disabled. PDIORH is enabled when the port D pins are functioning as general-purpose inputs/outputs (PD31 to PD16 for PDIORH) and TIOC inputs/outputs in MTU2S. In other states, PDIORH is disabled. A given pin on port D will be an output pin if the corresponding bit in PDIORL and PDIORH is set to 1, and an input pin if the bit is cleared to 0.

The initial values of PDIORL and PDIORH are both H'0000.

### 22.1.11 Port D Control Registers H1 to H4 and L1 to L4 (PDCRH1 to PDCRH4 and PDCRL1 to PDCRL4)

PDCRH1 to PDCRH4 and PDCRL1 to PDCRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port D.

- Port D Control Register H4 (PDCRH4)

|                |    |             |     |     |    |             |     |     |   |             |     |     |   |             |     |     |

### 22.1.13 Port E I/O Register L (PEIORL)

PEIORL is a 16-bit readable/writable register that is used to set the pins on port E as inputs or outputs. Bits PE15IOR to PE0IOR correspond to pins PE15 to PE0, respectively (multiplexed port pin names except for the port names are abbreviated here). PEIORL is enabled when the port E pins are functioning as general-purpose inputs/outputs (PE15 to PE0 for PEIORL) and TIOC inputs/outputs in both MTU2 and MTU2S. In other states, PEIORL is disabled. A given pin on port E will be an output pin if the corresponding bit in PEIORL is set to 1, and an input pin if the bit is cleared to 0.

The initial value of PEIORL is H'0000.

### 22.1.14 Port E Control Registers L1 to L4 (PECRL1 to PECRL4)

PECRL1 to PECRL4 are 16-bit readable/writable registers that are used to select the functions of the multiplexed pins on port E.

### 22.1.16 Large Current Port Control Register (HCPCR)

HCPCR is a 16-bit readable/writable register that is used to control the large current port. It controls pins PD10 to PD15, PD24 to PD29, PE0 to PE3, PE5, PE6, PE9, and PE11 to PE15.

## 22.1.17 IRQOUT Function Control Register (IFCR)

IFCR is a 16-bit readable/writable register that is used to control the  $\overline{\text{IRQOUT}}$  output and  $\overline{\text{REFOUT}}$  output when they are selected as the multiplexed pin functions for PB1 or PE15. If the function selected for the corresponding pin differs from this, the IFCR setting does not affect how the pin functions.

## 22.1.18 DACK Output Timing Control Register (PDACKCR)

PDACKCR is a 16-bit readable/writable register that is used to control the timing of the output of signals from the DACK0 to DACK3 pins. If the function selected for the corresponding pin differs from this, the PDACKCR setting does not affect how the pin functions.

Before setting this register, set the AL bit in DMCR to determine the active level for DACK signals. Additionally, when this register is used to change the timing of a DACK output, confirm that this provides the system with enough hold time for the writing of data during single-address transfer.

## 22.2 Pull-Up MOS Control by Pin Function

Table 22.9 shows the pull-up MOS control by pin function and the pull-up MOS control in each operating mode.

**Table 22.9 Pull-Up MOS Control**

| Pin Function                                                                                     | Power-On<br>Reset | Manual<br>Reset | Software<br>Standby | Sleep  | When<br>Oscillation<br>Stop is<br>Detected | When POE<br>Function is<br>Used | Normal<br>Operation |
|--------------------------------------------------------------------------------------------------|-------------------|-----------------|---------------------|--------|--------------------------------------------|---------------------------------|---------------------|
| I/O port input other than PB12 and PB13                                                          | Off               | On/off          | On/off              | On/off | On/off                                     | On/off                          | On/off              |

| TIC5U, TIC5V, and TIC5W input (MTU2)     |                   |                 |                     |       |                                            |                                 |                     |
| SCL and SDA input/output (IIC)           |                   |                 |                     |       |                                            |                                 |                     |
| MDC and TX_EN output (Ether)             |                   |                 |                     |       |                                            |                                 |                     |
| MII_TXD0 to MII_TXD3 output (Ether)      |                   |                 |                     |       |                                            |                                 |                     |
| TX_ER and MDIO output (Ether)            |                   |                 |                     |       |                                            |                                 |                     |

**[Legend]**

**Off:** Input pull-up MOS is always off.

**On/off:** Input pull-up MOS is on when the value of pull-up MOS control register is 1 and the pin is in input state or high impedance and off in other states.

**On/off\*:** Input pull-up MOS is on when the value of pull-up MOS control register is 1 and the pin is in high impedance and off in other states.

**Note:** \* For SCK (SCI, SCIF), MDIO (Ether), and MOSI, MISO, RSPCK, and SSL0 (RSPi) functions, when the pull-up MOS control register value is 1, if the input/output is switched, the on/off of the pull-up MOS also switched.

## 22.3 Usage Notes

1. In this LSI, the same function is available as a multiplexed function on multiple pins. This approach is intended to increase the number of selectable pin functions and to allow the easier design of boards. Note the following points when two or more pins are specified for one function.
  - When the pin function is input
 

Signals input to several pins are formed as one signal through OR or AND logic and the signal is transmitted into the LSI. Therefore, a signal that differs from the input signals may be transmitted to the LSI depending on the input signals in other pins that have the same functions. Table 22.10 shows the transmit forms of input functions allocated to several pins. When using one of the functions shown below in multiple pins, use it with care of signal polarity considering the transmit forms.

**Table 22.10 Transmission Format of Input Function Allocated on Multiple Pins**

| OR Type                                                                               | AND Type                                                  |
|---------------------------------------------------------------------------------------|-----------------------------------------------------------|
| TCLKA, TCLKB, TCLKC, TCLKD (MTU2)                                                     | IRQ0 to IRQ7 (INTC)                                       |
| TIOC0A, TIOC0B, TIOC0C, TIOC0D (MTU2)                                                 | DREQ0, DREQ1 (DMAC)                                       |
| TIOC1A, TIOC1B, TIOC2A (MTU2)                                                         | $\overline{\text{ADTRG}}$ (ADC)                           |
| TIC5U, TIC5V, TIC5W (MTU2)                                                            | $\overline{\text{WAIT}}$ , $\overline{\text{BREQ}}$ (BSC) |
| TIOC3AS, TIOC3BS, TIOC3CS, TIOC3DS (MTU2S)                                            | CRx0 (RCAN-ET)                                            |
| TIOC4AS, TIOC4BS, TIOC4CS, TIOC4DS (MTU2S)                                            |                                                           |
| SCK0 to SCK3, RXD0 to RXD3 (SCI, SCIF)                                                |                                                           |
| $\overline{\text{POE0}}$ , $\overline{\text{POE4}}$ , $\overline{\text{POE8}}$ (POE2) |                                                           |
| SSLO, MISO, MOSI, RSPCK (RSPI)                                                        |                                                           |
| LNKSTA, COL, CRS, MDIO, RX_CLK (Ether)                                                |                                                           |
| MII_RXD0 to MII_RXD3, RX_ER, RX_DV, TX_CLK (Ether)                                    |                                                           |

OR Type: Signals input to several pins are formed as one signal through OR logic and the signal is transmitted into the LSI.

AND Type: Signals input to several pins are formed as one signal through AND logic and the signal is transmitted into the LSI.

- When the pin function is output
 

Each selected pin can output the same function.

2. When the port input is switched from the low level to the DREQ edge or the IRQ edge for the pins that are multiplexed with I/O and DREQ or IRQ, the corresponding edge is detected.
3. Do not set functions other than settable functions. Otherwise, correct operation cannot be guaranteed.

## Section 23 I/O Ports

This LSI has six ports: A, B, C, D, E, and F. Port A is a 22-bit, port C is a 16-bit, port D is a 32-bit, and port E is a 16-bit I/O ports.

Port B has a 14-bit I/O port and a 2-bit input-only port. Port F is an 8-bit input-only port.

All port pins are multiplexed with other pin functions. The functions of the multiplex pins are selected by means of the pin function controller (PFC).

Each port is provided with data registers for storing the pin data.

### 23.1 Port A

Port A is an I/O port with 22 pins shown in figure 23.1.

Figure 23.1 Port A

### 23.1.1 Register Descriptions

Port A has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.1 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port A data register H | PADRH        | R/W | H'0000        | H'FFFE3800 | 8, 16, 32   |
| Port A data register L | PADRL        | R/W | H'0000        | H'FFFE3802 | 8, 16       |
| Port A port register H | PAPRH        | R   | —             | H'FFFE381C | 8, 16, 32   |
| Port A port register L | PAPRL        | R   | —             | H'FFFE381E | 8, 16       |

### 23.1.2 Port A Data Registers H and L (PADRH and PADRL)

PADRH and PADRL are 16-bit readable/writable registers that store port A data. Bits PA21DR to PA0DR correspond to pins PA21 to PA0, respectively (description of multiplexed functions are abbreviated here). When a pin function is general output, if a value is written to PADRH or PADRL, the value is output directly from the pin, and if PADRH or PADRL is read, the register value is returned directly regardless of the pin state. When a pin function is general input, if PADRH or PADRL is read, the pin state, not the register value, is returned directly. If a value is written to PADRH or PADRL, although that value is written into PADRH or PADRL, it does not affect the pin state.

Table 23.2 summarizes read/write operations of port A data register.

- Port A data register H (PADRH)

|                |    |    |    |    |    |    |   |   |   |   |            |            |            |            |            |            |

**Table 23.2 Port A Data Registers H and L (PADRH and PADRL) Read/Write Operations**

| PAIORH,<br>PAIOLR | Pin Function              | Read                 | Write                                                            |
|-------------------|---------------------------|----------------------|------------------------------------------------------------------|
| 0                 | General input             | Pin state            | Can write to PADRH and PADRL, but it has no effect on pin state. |
|                   | Other than general input  | Pin state            | Can write to PADRH and PADRL, but it has no effect on pin state. |
| 1                 | General output            | PADRH or PADRL value | The value written is output from the pin.                        |
|                   | Other than general output | PADRH or PADRL value | Can write to PADRH and PADRL, but it has no effect on pin state. |

**23.1.3 Port A Port Registers H and L (PAPRH and PAPRL)**

PAPRH and PAPRL are 16-bit read-only registers, which return the states of the pins. However, when the RSPI function is selected for PA12 and the Ethernet functions are selected for PA11 to PA6, the states of the corresponding pins cannot be read out. In this LSI, bits PA21PR to PA0PR correspond to pins PA21 to PA0, respectively (description of multiplexed functions are abbreviated here).

## 23.2 Port B

Port B is an I/O port with 16 pins shown in figure 23.2.

**Figure 23.2 Port B**

### 23.2.1 Register Descriptions

Port B has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.3 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port B data register L | PBDRL        | R/W | H'0000        | H'FFFE3882 | 8, 16       |
| Port B port register L | PBPRL        | R   | —             | H'FFFE389E | 8, 16       |

### 23.2.2 Port B Data Register L (PBDRL)

PBDRL is a 16-bit readable/writable register that stores port B data. Bits PB15DR, PB0DR correspond to pins PB15 to PB0, respectively (description of multiplexed functions are abbreviated here. When a pin function is general output, if a value is written to PBDRL, the value is output directly from the pin, and if PBDRL is read, the register value is returned directly regardless of the pin state. When a pin function is general input, if PBDRL is read, the pin state, not the register value, is returned directly. If a value is written to PBDRL, although that value is written into PBDRL, it does not affect the pin state. Note that pins PB13 and PB12 do not function as general output pins, and only functions as general input pins.

Table 23.4 summarizes read/write operations of port B data register.

- Port B data register L (PBDRL)

|                |        |        |        |        |        |        |       |       |       |       |       |       |       |       |       |       |

| 6   | PB6DR    | 0             | R/W |                |
| 5   | PB5DR    | 0             | R/W |                |
| 4   | PB4DR    | 0             | R/W |                |
| 3   | PB3DR    | 0             | R/W |                |
| 2   | PB2DR    | 0             | R/W |                |
| 1   | PB1DR    | 0             | R/W |                |
| 0   | PB0DR    | 0             | R/W |                |

**Table 23.4 Port B Data Register L (PBDRL) Read/Write Operations**

| PBIORL | Pin Function              | Read        | Write                                                  |
|--------|---------------------------|-------------|--------------------------------------------------------|
| 0      | General input             | Pin state   | Can write to PBDRL, but it has no effect on pin state. |
|        | Other than general input  | Pin state   | Can write to PBDRL, but it has no effect on pin state. |
| 1      | General output            | PBDRL value | The value written is output from the pin.              |
|        | Other than general output | PBDRL value | Can write to PBDRL, but it has no effect on pin state. |

**23.2.3 Port B Port Register L (PBPR L)**

PBPR L is a 16-bit read-only register, which returns the states of the pins. However, when the SCIF function is selected for PB3, and the TE bit in SCSCR and the SPB2IO bit in SCSPTTR are 0, the states of the corresponding pins cannot be read out. In this LSI, bits PB15PR to PB0PR correspond to pins PB15 to PB0, respectively (description of multiplexed functions are abbreviated here).

- Port B port register L (PBPR L)

| 0   | PB0PR    | Pin state     | R   |                                                                                         |

### 23.3 Port C

Port C is an I/O port with 16 pins shown in figure 23.3.

**Figure 23.3 Port C**

### 23.3.1 Register Descriptions

Port C has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.5 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port C data register L | PCDRL        | R/W | H'0000        | H'FFFE3902 | 8, 16       |
| Port C port register L | PCPRL        | R   | —             | H'FFFE391E | 8, 16       |

### 23.3.2 Port C Data Register L (PCDRL)

PCDRL is a 16-bit readable/writable register that store port C data. Bits PC15DR to PC0DR correspond to pins PC15 to PC0 (description of multiplexed functions are abbreviated) respectively. When a pin function is general output, if a value is written to PCDRL, the value is output directly from the pin, and if PCDRL is read, the register value is returned directly regardless of the pin state. When a pin function is general input, if PCDRL is read, the pin state, not the register value, is returned directly. If a value is written to PCDRL, although that value is written into PCDRL, it does not affect the pin state.

Table 23.6 summarizes read/write operations of port C data register.

- Port C data register L (PCDRL)

|                |            |            |            |            |            |            |           |           |           |           |           |           |           |           |           |           |

| R/W:           | R/W        | R/W        | R/W        | R/W        | R/W        | R/W        | R/W       | R/W       | R/W       | R/W       | R/W       | R/W       | R/W       | R/W       | R/W       | R/W       |

| Bit | Bit Name | Initial Value | R/W | Description     |
|-----|----------|---------------|-----|-----------------|
| 15  | PC15DR   | 0             | R/W | See table 23.6. |
| 14  | PC14DR   | 0             | R/W |                 |
| 13  | PC13DR   | 0             | R/W |                 |
| 12  | PC12DR   | 0             | R/W |                 |
| 11  | PC11DR   | 0             | R/W |                 |
| 10  | PC10DR   | 0             | R/W |                 |
| 9   | PC9DR    | 0             | R/W |                 |

| Bit | Bit Name | Initial Value | R/W | Description     |
|-----|----------|---------------|-----|-----------------|
| 8   | PC8DR    | 0             | R/W | See table 23.6. |
| 7   | PC7DR    | 0             | R/W |                 |
| 6   | PC6DR    | 0             | R/W |                 |
| 5   | PC5DR    | 0             | R/W |                 |
| 4   | PC4DR    | 0             | R/W |                 |
| 3   | PC3DR    | 0             | R/W |                 |
| 2   | PC2DR    | 0             | R/W |                 |
| 1   | PC1DR    | 0             | R/W |                 |
| 0   | PC0DR    | 0             | R/W |                 |

**Table 23.6 Port C Data Register L (PCDRL) Read/Write Operations**

| PCIORL | Pin Function              | Read        | Write                                                  |
|--------|---------------------------|-------------|--------------------------------------------------------|
| 0      | General input             | Pin state   | Can write to PCDRL, but it has no effect on pin state. |
|        | Other than general input  | Pin state   | Can write to PCDRL, but it has no effect on pin state. |
| 1      | General output            | PCDRL value | The value written is output from the pin.              |
|        | Other than general output | PCDRL value | Can write to PCDRL, but it has no effect on pin state. |

### 23.3.3 Port C Port Register L (PCPRL)

PCPRL is a 16-bit read-only register, which always returns the states of the pins regardless of the PFC setting. In this LSI, bits PC15PR to PC0PR correspond to pins PC15 to PC0, respectively (description of multiplexed functions are abbreviated here).

- Port C port register L (PCPRL)

|                |            |            |            |            |            |            |           |           |           |           |           |           |           |           |           |           |
|----------------|------------|------------|------------|------------|------------|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|

| 6   | PC6PR    | Pin state     | R   |                                                                                         |
| 5   | PC5PR    | Pin state     | R   |                                                                                         |
| 4   | PC4PR    | Pin state     | R   |                                                                                         |
| 3   | PC3PR    | Pin state     | R   |                                                                                         |
| 2   | PC2PR    | Pin state     | R   |                                                                                         |
| 1   | PC1PR    | Pin state     | R   |                                                                                         |
| 0   | PC0PR    | Pin state     | R   |                                                                                         |

## 23.4 Port D

Port D is an I/O port with 32 pins shown in figure 23.4.

**Figure 23.4 Port D**

### 23.4.1 Register Descriptions

Port D has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.7 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port D data register H | PDDRH        | R/W | H'0000        | H'FFFE3980 | 8, 16, 32   |
| Port D data register L | PDDRL        | R/W | H'0000        | H'FFFE3982 | 8, 16       |
| Port D port register H | PDPRH        | R   | —             | H'FFFE399C | 8, 16, 32   |
| Port D port register L | PDPRL        | R   | —             | H'FFFE399E | 8, 16       |

### 23.4.2 Port D Data Registers H and L (PDDRH and PDDRL)

PDDRH and PDDRL are 16-bit readable/writable registers that store port D data. In this LSI, bits PD31DR, to PD0DR correspond to pins PD31 to PD0, respectively (description of multiplexed functions are abbreviated here). When a pin function is general output, if a value is written to PDDRH or PDDRL, the value is output directly from the pin, and if PDDRH or PDDRL is read, the register value is returned directly regardless of the pin state. When a pin function is general input, if PDDRH or PDDRL is read, the pin state, not the register value, is returned directly. If a value is written to PDDRH or PDDRL, although that value is written into PDDRH or PDDRL, it does not affect the pin state.

Table 23.8 summarizes read/write operations of port D data register.

- Port D data register H (PDDRH)

|                |            |            |            |            |            |            |            |            |            |            |            |            |            |            |            |            |

**Table 23.8 Port D Data Registers H and L (PDDRH and PDDRL) Read/Write Operations**

- PDDRL bits 15 to 0

| <b>PDIORH,<br/>PDIORL</b> | <b>Pin Function</b>       | <b>Read</b>          | <b>Write</b>                                                     |
|---------------------------|---------------------------|----------------------|------------------------------------------------------------------|
| 0                         | General input             | Pin state            | Can write to PDDRH and PDDRL, but it has no effect on pin state. |
|                           | Other than general input  | Pin state            | Can write to PDDRH and PDDRL, but it has no effect on pin state. |
| 1                         | General output            | PDDRH or PDDRL value | The value written is output from the pin.                        |
|                           | Other than general output | PDDRH or PDDRL value | Can write to PDDRH and PDDRL, but it has no effect on pin state. |

### 23.4.3 Port D Port Registers H and L (PDPRH and PDPRL)

PDPRH and PDPRL are 16-bit read-only registers, which return the states of the pins. However, when the RSPI functions are selected for PD31 and PD30 and the Ethernet functions are selected for PD22 to PD20, the states of the corresponding pins cannot be read out. In this LSI, bits PD31PR to PD0PR correspond to pins PD31 to PD0, respectively (description of multiplexed functions are abbreviated here).

## 23.5 Port E

Port E is an I/O port with 16 pins shown in figure 23.5

**Figure 23.5 Port E**

### 23.5.1 Register Descriptions

Port E has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.9 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port E data register L | PEDRL        | R/W | H'0000        | H'FFFE3A02 | 8, 16       |
| Port E port register L | PEPRL        | R   | —             | H'FFFE3A1E | 8, 16       |

### 23.5.2 Port E Data Register L (PEDRL)

PEDRL is a 16-bit readable/writable register that stores port E data. In this LSI, bits PE15DR to PE0DR correspond to pins PE15 to PE0, respectively (description of multiplexed functions are abbreviated here). When a pin function is general output, if a value is written to PEDRL, the value is output directly from the pin, and if PEDRL is read, the register value is returned directly regardless of the pin state. When a pin function is general input, if PEDRL is read, the pin state, not the register value, is returned directly. If a value is written to PEDRL, although that value is written into PEDRL, it does not affect the pin state.

Table 23.10 summarizes read/write operations of port E data register.

- Port E data register L (PEDRL)

| 10  | PE10DR   | 0             | R/W |                  |
| 9   | PE9DR    | 0             | R/W |                  |
| 8   | PE8DR    | 0             | R/W |                  |
| 7   | PE7DR    | 0             | R/W |                  |
| 6   | PE6DR    | 0             | R/W |                  |
| 5   | PE5DR    | 0             | R/W |                  |
| 4   | PE4DR    | 0             | R/W |                  |
| 3   | PE3DR    | 0             | R/W |                  |
| 2   | PE2DR    | 0             | R/W |                  |
| 1   | PE1DR    | 0             | R/W |                  |
| 0   | PE0DR    | 0             | R/W |                  |

**Table 23.10 Port E Data Register L (PEDRL) Read/Write Operations**

| PEIORL | Pin Function              | Read        | Write                                                  |
|--------|---------------------------|-------------|--------------------------------------------------------|
| 0      | General input             | Pin state   | Can write to PEDRL, but it has no effect on pin state. |
|        | Other than general input  | Pin state   | Can write to PEDRL, but it has no effect on pin state. |
| 1      | General output            | PEDRL value | The value written is output from the pin.              |
|        | Other than general output | PEDRL value | Can write to PEDRL, but it has no effect on pin state. |

### 23.5.3 Port E Port Register L (PEPRL)

PEPRL is a 16-bit read-only register, which returns the states of the pins. However, when the TE bit in SCSCR and the SPB2IO bit in SCSPT are 0, and the RSPI functions are selected for PE10, PE8, and PE7, the Ethernet functions are selected for PE15 to PE11, PE9, PE8, PE2, and PE1, and the SCIF function is selected for PE5, the states of the corresponding pins cannot be read out. In this LSI, bits PE15PR to PE0PR correspond to pins PE15 to PE0, respectively (description of multiplexed functions are abbreviated here).

- Port E port register L (PEPRL)

|                |        |        |        |        |        |        |       |       |       |       |       |       |       |       |       |       |
|----------------|--------|--------|--------|--------|--------|--------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|

| 1   | PE1PR    | Pin state     | R   |                                                                                         |
| 0   | PE0PR    | Pin state     | R   |                                                                                         |

## 23.6 Port F

Port F is an I/O port with 8 pins shown in figure 23.6.

**Figure 23.6 Port F**

### 23.6.1 Register Descriptions

Port F has the following registers. See section 32, List of Registers for details on the register address and states in each operating mode.

**Table 23.11 Register Configuration**

| Register Name          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|------------------------|--------------|-----|---------------|------------|-------------|
| Port F data register L | PFDRL        | R   | —             | H'FFFE3A82 | 8, 16       |

### 23.6.2 Port F Data Register L (PFDRL)

PFDRL is a 16-bit read-only register that stores port F data. In this LSI, bits PF7DR to PF0DR correspond to pins PF7 to PF0, respectively (description of multiplexed functions are abbreviated here).

Even if a value is written to PFDR, the value is not written into PFDRL, and it does not affect the pin state. If PFDR is read, the pin state, not the register value, is returned directly. However, when sampling the analog input of A/D converter, 1 is read. Table 23.12 summarizes read/write operations of port F data register.

- Port F data register L (PFDRL)

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|----------------|----|----|----|----|----|----|---|---|-------|-------|-------|-------|-------|-------|-------|-------|
|                | -  | -  | -  | -  | -  | -  | - | - | PF7DR | PF6DR | PF5DR | PF4DR | PF3DR | PF2DR | PF1DR | PF0DR |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | *     | *     | *     | *     | *     | *     | *     | *     |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R     | R     | R     | R     | R     | R     | R     | R     |

| Bit     | Bit Name | Initial Value | R/W | Description                                                          |
|---------|----------|---------------|-----|----------------------------------------------------------------------|
| 15 to 8 | —        | All 0         | R   | Reserved                                                             |
|         |          |               |     | These bits are always read as 0. The write value should always be 0. |
| 7       | PF7DR    | Pin state     | R   | See table 23.12.                                                     |
| 6       | PF6DR    | Pin state     | R   |                                                                      |
| 5       | PF5DR    | Pin state     | R   |                                                                      |
| 4       | PF4DR    | Pin state     | R   |                                                                      |
| 3       | PF3DR    | Pin state     | R   |                                                                      |
| 2       | PF2DR    | Pin state     | R   |                                                                      |
| 1       | PF1DR    | Pin state     | R   |                                                                      |
| 0       | PF0DR    | Pin state     | R   |                                                                      |

**Table 23.12 Port F Data Register L (PFDRL) Read/Write Operations**

| Pin Function  | Read      | Write                            |
|---------------|-----------|----------------------------------|
| General input | Pin state | Ignored (no effect on pin state) |
| ANn input     | 1         | Ignored (no effect on pin state) |

## 23.7 Usage Notes

### 23.7.1 Handling of Unused pins

Levels on unused pins of port F should be fixed by connection to  $AV_{cc}$  or  $AV_{ss}$  via resistances. For handling of the NMI, USD+, USD-, EXTAL, XTAL, USBEXTAL, USBXTAL,  $\overline{WDTOVF}$ ,  $\overline{TRST}$ , TMS, TCK, TDO, and TDI pins, follow the instructions in the sections on the corresponding modules. Other unused pins should be connected to  $V_{ccQ}$  or GND via resistors to fix high or low levels on the pins.

## Section 24 USB Function Module (USB)

This LSI incorporates a USB function module (USB).

### 24.1 Features

- Automatic processing of USB protocol with on-chip protocol processor and transceiver conforming to USB2.0

Automatic processing of USB standard commands for endpoint 0 (some commands and class/vendor commands require decoding and processing by firmware)

- Transfer speed: Full-speed (12 Mbps)
- Endpoint configuration

| Endpoint Name | Abbreviation | Transfer Type | Maximum Packet Size | FIFO Buffer Capacity (Byte) | DMA/DTC Transfer |
|---------------|--------------|---------------|---------------------|-----------------------------|------------------|
| Endpoint 0    | EP0s         | Setup         | 8                   | 8                           | —                |
|               | EP0i         | Control IN    | 16                  | 16                          | —                |
|               | EP0o         | Control OUT   | 16                  | 16                          | —                |
| Endpoint 1    | EP1          | Bulk OUT      | 64                  | 128                         | Possible         |
| Endpoint 2    | EP2          | Bulk IN       | 64                  | 128                         | Possible         |
| Endpoint 3    | EP3          | Interrupt IN  | 16                  | 16                          | —                |
| Endpoint 4    | EP4          | Bulk OUT      | 64                  | 128                         | Possible         |
| Endpoint 5    | EP5          | Bulk IN       | 64                  | 128                         | Possible         |
| Endpoint 6    | EP6          | Interrupt IN  | 16                  | 16                          | —                |
| Endpoint 7    | EP7          | Bulk OUT      | 64                  | 64                          | —                |
| Endpoint 8    | EP8          | Bulk IN       | 64                  | 64                          | —                |
| Endpoint 9    | EP9          | Interrupt IN  | 16                  | 16                          | —                |

- **Interrupt requests:** Generates various interrupt signals necessary for USB transmission/reception
- **Clock\*:** External input (48 MHz)  
Internal input (only when 12-MHz EXTAL is used)
- **Power-down mode**  
Power consumption can be reduced by stopping the protocol-processor internal clock when USB cable is disconnected.
- **Power mode:** Self-powered mode

Note: \* Use the USBSEL bit in the standby control register 6 (STBCR6) for selection of the clock. For details, see section 30.3.6, Standby Control Register 6 (STBCR6).

Figure 24.1 shows a block diagram of the USB.

**Figure 24.1 Block Diagram of USB**

## 24.2 Pin Configuration

Table 24.1 lists input/output pins and their functions of the USB.

**Table 24.1 Pin Configuration**

| Pin Name    | I/O    | Function                                                             |
|-------------|--------|----------------------------------------------------------------------|
| VBUS        | Input  | USB cable connection monitor pin                                     |
| USD+        | I/O    | USB data input/output pin                                            |
| USD-        | I/O    | USB data input/output pin                                            |
| DrVcc       | Input  | USB on-chip transceiver power supply pin (3.0 to 3.6V, DrVcc = VccQ) |
| DrVss       | Input  | USB on-chip transceiver ground pin (Connect to Vss)                  |
| USBEXTAL    | Input  | Connected to a 48-MHz resonator for USB                              |
| USBXTAL     | Output | Connected to a 48-MHz resonator for USB                              |
| PUPD (PB15) | Output | Pull-up control                                                      |

## 24.3 Register Descriptions

The USB has the following registers.

**Table 24.2 Register Configuration**

| Register Name                   | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------------------------------|--------------|-----|---------------|------------|-------------|
| USB interrupt flag register 0   | USBIFR0      | R/W | H'0x          | H'FFFE7000 | 8           |
| USB interrupt flag register 1   | USBIFR1      | R/W | H'00          | H'FFFE7001 | 8           |
| USB interrupt flag register 2   | USBIFR2      | R/W | H'06          | H'FFFE7002 | 8           |
| USB interrupt flag register 3   | USBIFR3      | R/W | H'06          | H'FFFE7003 | 8           |
| USB interrupt flag register 4   | USBIFR4      | R/W | H'04          | H'FFFE7004 | 8           |
| USB interrupt enable register 0 | USBIER0      | R/W | H'00          | H'FFFE7008 | 8           |
| USB interrupt enable register 1 | USBIER1      | R/W | H'00          | H'FFFE7009 | 8           |
| USB interrupt enable register 2 | USBIER2      | R/W | H'00          | H'FFFE700A | 8           |
| USB interrupt enable register 3 | USBIER3      | R/W | H'00          | H'FFFE700B | 8           |
| USB interrupt enable register 4 | USBIER4      | R/W | H'00          | H'FFFE700C | 8           |
| USB interrupt select register 0 | USBISR0      | R/W | H'00          | H'FFFE7010 | 8           |
| USB interrupt select register 1 | USBISR1      | R/W | H'00          | H'FFFE7011 | 8           |
| USB interrupt select register 2 | USBISR2      | R/W | H'00          | H'FFFE7012 | 8           |
| USB interrupt select register 3 | USBISR3      | R/W | H'00          | H'FFFE7013 | 8           |
| USB interrupt select register 4 | USBISR4      | R/W | H'00          | H'FFFE7014 | 8           |
| USBEP0i data register           | USBEPDR0i    | W   | Undefined     | H'FFFE7020 | 8, 16, 32   |
| USBEP0o data register           | USBEPDR0o    | R   | Undefined     | H'FFFE7024 | 8, 16, 32   |
| USBEP0s data register           | USBEPDR0s    | R   | Undefined     | H'FFFE7028 | 8, 16, 32   |
| USBEP1 data register            | USBEPDR1     | R   | Undefined     | H'FFFE7030 | 8, 16, 32   |
| USBEP2 data register            | USBEPDR2     | W   | Undefined     | H'FFFE7034 | 8, 16, 32   |
| USBEP3 data register            | USBEPDR3     | W   | Undefined     | H'FFFE7038 | 8, 16, 32   |
| USBEP4 data register            | USBEPDR4     | R   | Undefined     | H'FFFE7040 | 8, 16, 32   |
| USBEP5 data register            | USBEPDR5     | W   | Undefined     | H'FFFE7044 | 8, 16, 32   |
| USBEP6 data register            | USBEPDR6     | W   | Undefined     | H'FFFE7048 | 8, 16, 32   |
| USBEP7 data register            | USBEPDR7     | R   | Undefined     | H'FFFE7050 | 8, 16, 32   |

### 24.3.1 USB Interrupt Flag Register 0 (USBIFR0)

Together with USB interrupt flag registers 1 to 4 (USBIFR1 to USBIFR4), USBIFR0 indicates interrupt status information required by the application. When an interrupt occurs, the corresponding bit is set to 1 and an interrupt request is sent to the CPU according to the combination with the USB interrupt enable register 0 (USBIER0). Clearing is performed by writing 0 to the bit to be cleared, and 1 to the other bits. However, VBUSMN is a status bit, and cannot be cleared.

|                |        |        |   |   |        |        |        |        |
|----------------|--------|--------|---|---|--------|--------|--------|--------|
| Bit:           | 7      | 6      | 5 | 4 | 3      | 2      | 1      | 0      |
|                | BRST   | CFDN   | - | - | SETC   | SETI   | VBUSMN | VBUSF  |
| Initial value: | 0      | 0      | 0 | 0 | 0      | 0      | -      | 0      |
| R/W:           | R/(W)* | R/(W)* | R | R | R/(W)* | R/(W)* | R      | R/(W)* |

Note: \* Only 0 can be written to clear the flag.

| Bit  | Bit Name | Initial Value | R/W    | Description                                                                                                                                                                                                                                                                           |

### 24.3.2 USB Interrupt Flag Register 1 (USBIFR1)

Together with USB interrupt flag registers 0, 2, 3, and 4 (USBIFR0, USBIFR2, USBIFR3, and USBIFR4), USBIFR1 indicates interrupt status information required by the application. When an interrupt occurs, the corresponding bit is set to 1 and an interrupt request is sent to the CPU according to the combination with the USB interrupt enable register 1 (USBIER1). Clearing is performed by writing 0 to the bit to be cleared, and 1 to the other bits.

### 24.3.3 USB Interrupt Flag Register 2 (USBIFR2)

Together with USB interrupt flag registers 0, 1, 3, and 4 (USBIFR0, USBIFR1, USBIFR3, and USBIFR4), USBIFR2 indicates interrupt status information required by the application. When an interrupt occurs, the corresponding bit is set to 1 and an interrupt request is sent to the CPU according to the combination with the USB interrupt enable register 2 (USBIER2). Clearing is performed by writing 0 to the bit to be cleared, and 1 to the other bits. However, EP1FULL, EP2ALLEMP, and EP2EMPTY are status bits, and cannot be cleared.

### 24.3.5 USB Interrupt Flag Register 4 (USBIFR4)

Together with USB interrupt flag registers 0 to 3 (USBIFR0 to USBIFR3), USBIFR4 indicates interrupt status information required by the application. When an interrupt occurs, the corresponding bit is set to 1 and an interrupt request is sent to the CPU according to the combination with the USB interrupt enable register 4 (USBIER4). Clearing is performed by writing 0 to the bit to be cleared, and 1 to the other bits. However, EP7FULL and EP8EMPTY are status bits, and cannot be cleared.

### 24.3.6 USB Interrupt Enable Register 0 (USBIER0)

USBIER0 enables the interrupt requests indicated in the USB interrupt flag register 0 (USBIFR0). When an interrupt flag is set while the corresponding bit in USBIER0 is set to 1, an interrupt request is sent to the CPU. The interrupt vector number is determined by the content of the USB interrupt select register 0 (USBISR0).

### 24.3.7 USB Interrupt Enable Register 1 (USBIER1)

USBIER1 enables the interrupt requests indicated in the USB interrupt flag register 1 (USBIFR1). When an interrupt flag is set while the corresponding bit in USBIER1 is set to 1, an interrupt request is sent to the CPU. The interrupt vector number is determined by the content of the USB interrupt select register 1 (USBISR1).

### 24.3.8 USB Interrupt Enable Register 2 (USBIER2)

USBIER2 enables the interrupt requests indicated in the USB interrupt flag register 2 (USBIFR2). When an interrupt flag is set while the corresponding bit in USBIER2 is set to 1, an interrupt request is sent to the CPU. The interrupt vector number is determined by the content of the USB interrupt select register 2 (USBISR2).

### 24.3.9 USB Interrupt Enable Register 3 (USBIER3)

USBIER3 enables the interrupt requests indicated in the USB interrupt flag register 3 (USBIFR3). When an interrupt flag is set while the corresponding bit in USBIER3 is set to 1, an interrupt request is sent to the CPU. The interrupt vector number is determined by the content of the USB interrupt select register 3 (USBISR3).

### 24.3.10 USB Interrupt Enable Register 4 (USBIER4)

USBIER4 enables the interrupt requests indicated in the USB interrupt flag register 4 (USBIFR4). When an interrupt flag is set while the corresponding bit in USBIER4 is set to 1, an interrupt request is sent to the CPU. The interrupt vector number is determined by the content of the USB interrupt select register 4 (USBISR4).

### 24.3.11 USB Interrupt Select Register 0 (USBISR0)

USBISR0 selects the vector numbers of the interrupt requests indicated in the USB interrupt flag register 0 (USBIFR0). If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR0 is cleared to 0, the interrupt will be USI0. If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR0 is set to 1, the interrupt will be USI1. If interrupts occur simultaneously, USI0 has priority by default.

### 24.3.12 USB Interrupt Select Register 1 (USBISR1)

USBISR1 selects the vector numbers of the interrupt requests indicated in the USB interrupt flag register 1 (USBIFR1). If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR1 is cleared to 0, the interrupt will be USI0. If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR1 is set to 1, the interrupt will be USI1. If interrupts occur simultaneously, USI0 has priority by default.

### 24.3.13 USB Interrupt Select Register 2 (USBISR2)

USBISR2 selects the vector numbers of the interrupt requests indicated in the USB interrupt flag register 2 (USBIFR2). If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR2 is cleared to 0, the interrupt will be USI0. If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR2 is set to 1, the interrupt will be USI1. If interrupts occur simultaneously, USI0 has priority by default.

| 0    | EP1FULLS  | 0             | R/W | EP1 FIFO full                                                                    |

24.3.14 USB Interrupt Select Register 3 (USBISR3)

USBISR3 selects the vector numbers of the interrupt requests indicated in the USB interrupt flag register 3 (USBIFR3). If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR3 is cleared to 0, the interrupt will be USI0. If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR3 is set to 1, the interrupt will be USI1. If interrupts occur simultaneously, USI0 has priority by default.

### 24.3.15 USB Interrupt Select Register 4 (USBISR4)

USBISR4 selects the vector numbers of the interrupt requests indicated in the USB interrupt flag register 4 (USBIFR4). If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR4 is cleared to 0, the interrupt will be USI0. If the USB issues an interrupt request to the INTC when the corresponding bit in USBISR4 is set to 1, the interrupt will be USI1. If interrupts occur simultaneously, USI0 has priority by default.

24.3.16 USBEP0i Data Register (USBEPDR0i)

USBEPDR0i is a 16-byte transmit FIFO buffer for endpoint 0, holding one packet of transmit data for control IN. Transmit data is fixed by writing one packet of data and setting the EP0iPKTE bit in the USB trigger register 0 (USBTRG0). When an ACK handshake is returned from the host after the data has been transmitted, the EP0iTS bit in the USB interrupt flag register 1 (USBIFR1) is set to 1. USBEPDR0i can be initialized by the EP0iCLR bit in the USB FIFO clear register 0 (USBFCLR0). The read value is undefined.

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

| 7 to 0 | D7 to D0 | —             | W   | Data register for control IN transfer |

24.3.17 USBEP0o Data Register (USBEPDR0o)

USBEPDR0o is a 16-byte receive FIFO buffer for endpoint 0 to store endpoint 0 receive data other than setup commands. When data is received normally, the EP0oTS bit in the USB interrupt flag register 1 (USBIFR1) is set, and the number of receive bytes is indicated in the USBEP0o receive data size register (USBEPSZ0o). After the data has been read, setting the EP0oRDFN bit in the USB trigger register 0 (USBTRG0) enables the next packet to be received. USBEPDR0o can be initialized by the EP0oCLR bit in the USB FIFO clear register 0 (USBFCLR0).

| 7 to 0 | D7 to D0 | —             | R   | Data register for control OUT transfer |

### 24.3.18 USBEP0s Data Register (USBEPDR0s)

USBEPDR0s is an 8-byte FIFO buffer specifically for receiving endpoint 0 setup commands. USBEPDR0s receives only setup commands requiring processing on the application side. When a command that this module automatically processes is received, it is not stored. When command data is stored normally, the SETUPTS bit in the USB interrupt flag register 1 (USBIFR1) is set.

As a setup command must be received without fail, if data is left in this buffer, it will be overwritten with new data. If reception of the next command is started while the current command is being read, command reception has priority and data read by the application is forcibly disabled. Therefore the read data is invalid.

| 7 to 0 | D7 to D0 | —             | R   | Register for storing the setup command on control OUT transfer |

24.3.19 USBEP1 Data Register (USBEPDR1)

USBEPDR1 is a 128-byte receive FIFO buffer for endpoint 1. USBEPDR1 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When one packet of data is received normally from the host, the EP1FULL bit in the USB interrupt flag register 2 (USBIFR2) is set. The number of receive bytes is indicated in the USB EP1 receive data size register (USBEPSZ1). After the data has been read, the buffer that was read is enabled to receive again by writing 1 to the EP1RDFN bit in the USB trigger register 1 (USBTRG1). The receive data in this FIFO buffer can be transferred by DMA or DTC (byte-by-byte dual-address transfer). USBEPDR1 can be initialized by the EP1CLR bit in the USB FIFO clear register 1 (USBFCLR1).

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | R  | R  | R  | R  | R  | R  | R  | R  |

|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | R   | Data register for endpoint 1 transfer |

24.3.20 USBEP2 Data Register (USBEPDR2)

USBEPDR2 is a 128-byte transmit FIFO buffer for endpoint 2. USBEPDR2 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When transmit data is written to this FIFO buffer and the EP2PKTE bit in the USB trigger register 1 (USBTRG1) is set, one packet of transmit data is fixed, and the dual buffer is switched over. Transmit data for this FIFO buffer can be transferred by DMA or DTC (byte-by-byte dual-address transfer). USBEPDR2 can be initialized by the EP2CLR bit in the USB FIFO clear register 1 (USBFCLR1). The read value is undefined.

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 2 transfer |

### 24.3.21 USBEP3 Data Register (USBEPDR3)

USBEPDR3 is a 16-byte transmit FIFO buffer for endpoint 3, holding one packet of transmit data in endpoint 3 interrupt transfer. Transmit data is fixed by writing one packet of data and setting the EP3PKTE bit in the USB trigger register 1 (USBTRG1). USBEPDR3 can be initialized by the EP3CLR bit in the USB FIFO clear register 1 (USBFCLR1). The read value is undefined.

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | W  | W  | W  | W  | W  | W  | W  | W  |

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 3 transfer |

### 24.3.22 USBEP4 Data Register (USBEPDR4)

USBEPDR4 is a 128-byte receive FIFO buffer for endpoint 4. USBEPDR1 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When one packet of data is received normally from the host, the EP4FULL bit in the USB interrupt flag register 3 (USBIFR3) is set. The number of receive bytes is indicated in the USB EP4 receive data size register (USBEPSZ4). After the data has been read, the buffer that was read is enabled to receive again by writing 1 to the EP4RDFN bit in the USB trigger register 2 (USBTRG2). The receive data in this FIFO buffer can be transferred by DMA or DTC (byte-by-byte dual-address transfer). USBEPDR4 can be initialized by the EP4CLR bit in the USB FIFO clear register 2 (USBFCLR2).

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | R  | R  | R  | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | R   | Data register for endpoint 4 transfer |

24.3.23 USBEP5 Data Register (USBEPDR5)

USBEPDR5 is a 128-byte transmit FIFO buffer for endpoint 5. USBEPDR5 has a dual-buffer configuration, and has a capacity of twice the maximum packet size. When transmit data is written to this FIFO buffer and the EP5PKTE bit in the USB trigger register 2 (USBTRG2) is set, one packet of transmit data is fixed, and the dual buffer is switched over. Transmit data for this FIFO buffer can be transferred by DMA or DTC (byte-by-byte dual-address transfer). USBEPDR5 can be initialized by the EP5CLR bit in the USB FIFO clear register 2 (USBFCLR2). The read value is undefined.

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 5 transfer |

24.3.24 USBEP6 Data Register (USBEPDR6)

USBEPDR6 is a 16-byte transmit FIFO buffer for endpoint 6, holding one packet of transmit data in endpoint 6 interrupt transfer. Transmit data is fixed by writing one packet of data and setting the EP6PKTE bit in the USB trigger register 2 (USBTRG2). USBEPDR6 can be initialized by the EP6CLR bit in the USB FIFO clear register 2 (USBFCLR2). The read value is undefined.

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 6 transfer |

### 24.3.25 USBEP7 Data Register (USBEPDR7)

USBEPDR7 is a 64-byte receive FIFO buffer for endpoint 7. When one packet of data is received normally from the host, the EP7FULL bit in the USB interrupt flag register 4 (USBIFR4) is set. The number of receive bytes is indicated in the USB EP7 receive data size register (USBEPSZ7). After the data has been read, the buffer that was read is enabled to receive again by writing 1 to the EP7RDFN bit in the USB trigger register 3 (USBTRG3). USBEPDR7 can be initialized by the EP7CLR bit in the USB FIFO clear register 3 (USBFCLR3).

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | R  | R  | R  | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | R   | Data register for endpoint 7 transfer |

### 24.3.26 USBEP8 Data Register (USBEPDR8)

USBEPDR8 is a 64-byte transmit FIFO buffer for endpoint 8. Transmit data for one packet is fixed by writing transmit data to this FIFO buffer and setting the EP8PKTE bit in the USB trigger register 3 (USBTRG3). USBEPDR8 can be initialized by the EP8CLR bit in the USB FIFO clear register 3 (USBFCLR3). The read value is undefined.

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | W  | W  | W  | W  | W  | W  | W  | W  |

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 8 transfer |

### 24.3.27 USBEP9 Data Register (USBEPDR9)

USBEPDR9 is a 16-byte transmit FIFO buffer for endpoint 9, holding one packet of transmit data in endpoint 9 interrupt transfer. Transmit data is fixed by writing one packet of data and setting the EP9PKTE bit in the USB trigger register 3 (USBTRG3). USBEPDR9 can be initialized by the EP9CLR bit in the USB FIFO clear register 3 (USBFCLR3). The read value is undefined.

|                |    |    |    |    |    |    |    |    |
|----------------|----|----|----|----|----|----|----|----|
| Bit:           | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | -  | -  | -  | -  | -  | -  | -  | -  |
| R/W:           | W  | W  | W  | W  | W  | W  | W  | W  |

| Bit    | Bit Name | Initial Value | R/W | Description                           |
|--------|----------|---------------|-----|---------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Data register for endpoint 9 transfer |

### 24.3.28 USBEP0o Receive Data Size Register (USBEPSZ0o)

USBEPSZ0o indicates, in bytes, the amount of data received from the host by endpoint 0.

|                |   |   |   |    |    |    |    |    |
|----------------|---|---|---|----|----|----|----|----|
| Bit:           | 7 | 6 | 5 | 4  | 3  | 2  | 1  | 0  |
|                | - | - | - | D4 | D3 | D2 | D1 | D0 |
| Initial value: | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  |
| R/W:           | R | R | R | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                                  |
|--------|----------|---------------|-----|----------------------------------------------|
| 7 to 5 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. |
| 4 to 0 | D4 to D0 | All 0         | R   | Number of bytes received by endpoint 0       |

### 24.3.29 USBEP1 Receive Data Size Register (USBEPSZ1)

USBEPSZ1 indicates, in bytes, the amount of data received from the host by endpoint 1. The endpoint 1 FIFO buffer has a dual-FIFO configuration. This register indicates the receive data size of the currently selected FIFO (that can be read by CPU).

|                |   |    |    |    |    |    |    |    |
|----------------|---|----|----|----|----|----|----|----|
| Bit:           | 7 | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | - | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| R/W:           | R | R  | R  | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                               |
|--------|----------|---------------|-----|-------------------------------------------|
| 7      | —        | All 0         | R   | Reserved<br>This bit is always read as 0. |
| 6 to 0 | D6 to D0 | All 0         | R   | Number of bytes received by endpoint 1    |

### 24.3.30 USBEP4 Receive Data Size Register (USBEPSZ4)

USBEPSZ4 indicates, in bytes, the amount of data received from the host by endpoint 4. The endpoint 4 FIFO buffer has a dual-FIFO configuration. This register indicates the receive data size of the currently selected FIFO (that can be read by CPU).

|                |   |    |    |    |    |    |    |    |
|----------------|---|----|----|----|----|----|----|----|
| Bit:           | 7 | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | - | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| R/W:           | R | R  | R  | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                               |
|--------|----------|---------------|-----|-------------------------------------------|
| 7      | —        | All 0         | R   | Reserved<br>This bit is always read as 0. |
| 6 to 0 | D6 to D0 | All 0         | R   | Number of bytes received by endpoint 4    |

### 24.3.31 USBEP7 Receive Data Size Register (USBEPSZ7)

USBEPSZ7 indicates, in bytes, the amount of data received from the host by endpoint 7.

|                |   |    |    |    |    |    |    |    |
|----------------|---|----|----|----|----|----|----|----|
| Bit:           | 7 | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|                | - | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| Initial value: | 0 | 0  | 0  | 0  | 0  | 0  | 0  | 0  |
| R/W:           | R | R  | R  | R  | R  | R  | R  | R  |

| Bit    | Bit Name | Initial Value | R/W | Description                               |
|--------|----------|---------------|-----|-------------------------------------------|
| 7      | —        | All 0         | R   | Reserved<br>This bit is always read as 0. |
| 6 to 0 | D6 to D0 | All 0         | R   | Number of bytes received by endpoint 7    |

### 24.3.32 USB Data Status Register 0 (USBDASTS0)

USBDASTS0 indicates whether the transmit FIFO buffer contains valid data. The EP0iDE bit is set to 1 when data is written to the corresponding FIFO buffer and the packet enable state is set. This bit is cleared when data has been completely transmitted to the host.

|                |   |   |   |   |   |   |   |        |
|----------------|---|---|---|---|---|---|---|--------|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0      |
|                | - | - | - | - | - | - | - | EP0iDE |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0      |
| R/W:           | R | R | R | R | R | R | R | R      |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                     |
|--------|----------|---------------|-----|-------------------------------------------------------------------------------------------------|
| 7 to 1 | —        | All 0         | R   | Reserved<br>These bits are always read as 0.                                                    |
| 0      | EP0iDE   | 0             | R   | EP0i Data Present<br>This bit is set to 1 when the endpoint 0i FIFO buffer contains valid data. |

### 24.3.33 USB Data Status Register 1 (USBDASTS1)

USBDASTS1 indicates whether the transmit FIFO buffer contains valid data. The EP2DE or EP3DE bit is set to 1 when data is written to the corresponding FIFO buffer and the packet enable state is set. This bit is cleared when data has been completely transmitted to the host.

|                |   |   |   |   |   |       |       |   |
|----------------|---|---|---|---|---|-------|-------|---|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2     | 1     | 0 |
|                | - | - | - | - | - | EP3DE | EP2DE | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0     | 0     | 0 |
| R/W:           | R | R | R | R | R | R     | R     | R |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                   |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------|
| 7 to 3 | —        | All 0         | R   | Reserved<br>These bits are always read as 0.                                                  |
| 2      | EP3DE    | 0             | R   | EP3 Data Present<br>This bit is set to 1 when the endpoint 3 FIFO buffer contains valid data. |
| 1      | EP2DE    | 0             | R   | EP2 Data Present<br>This bit is set to 1 when the endpoint 2 FIFO buffer contains valid data. |
| 0      | —        | 0             | R   | Reserved<br>This bit is always read as 0.                                                     |

### 24.3.34 USB Data Status Register 2 (USBDASTS2)

USBDASTS2 indicates whether the transmit FIFO buffer contains valid data. The EP5DE or EP6DE bit is set to 1 when data is written to the corresponding FIFO buffer and the packet enable state is set. This bit is cleared when data has been completely transmitted to the host.

|                |   |   |   |   |   |       |       |   |
|----------------|---|---|---|---|---|-------|-------|---|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2     | 1     | 0 |
|                | - | - | - | - | - | EP6DE | EP5DE | - |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0     | 0     | 0 |
| R/W:           | R | R | R | R | R | R     | R     | R |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                   |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------|
| 7 to 3 | —        | All 0         | R   | Reserved<br>These bits are always read as 0.                                                  |
| 2      | EP6DE    | 0             | R   | EP6 Data Present<br>This bit is set to 1 when the endpoint 6 FIFO buffer contains valid data. |
| 1      | EP5DE    | 0             | R   | EP5 Data Present<br>This bit is set to 1 when the endpoint 5 FIFO buffer contains valid data. |
| 0      | —        | 0             | R   | Reserved<br>This bit is always read as 0.                                                     |

### 24.3.35 USB Data Status Register 3 (USBDASTS3)

USBDASTS3 indicates whether the transmit FIFO buffer contains valid data. The EP8DE or EP9DE bit is set to 1 when data is written to the corresponding FIFO buffer and the packet enable state is set. This bit is cleared when data has been completely transmitted to the host.

### 24.3.36 USB Trigger Register 0 (USBTRG0)

USBTRG0 is a write-only register that generates one-shot triggers to control the transmit/receive sequence for endpoint 0. The read value of this register is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

|                |   |   |   |   |   |              |              |              |

### 24.3.40 USB FIFO Clear Register 0 (USBFCLR0)

USBFCLR0 is a write-only register to initialize the FIFO buffers for endpoint 0. Writing 1 to a bit clears all the data in the corresponding FIFO buffer. The corresponding interrupt flag is not cleared. Do not clear the FIFO buffer during transmission/reception. The read value of this register is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

### 24.3.42 USB FIFO Clear Register 2 (USBFCLR2)

USBFCLR2 is a write-only register to initialize the FIFO buffers for each endpoint. Writing 1 to a bit clears all the data in the corresponding FIFO buffer. The corresponding interrupt flag is not cleared. Do not clear the FIFO buffer during transmission/reception. The read value of this register is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

|                |   |   |   |   |   |            |            |            |
|----------------|---|---|---|---|---|------------|------------|------------|

### 24.3.43 USB FIFO Clear Register 3 (USBFCLR3)

USBFCLR3 is a write-only register to initialize the FIFO buffers for each endpoint. Writing 1 to a bit clears all the data in the corresponding FIFO buffer. The corresponding interrupt flag is not cleared. Do not clear the FIFO buffer during transmission/reception. The read value of this register is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

24.3.44 USB Endpoint Stall Register 0 (USBEPSTL0)

The bits in USBEPSTL0 are used to forcibly stall the endpoints on the application side. While a bit is set to 1, the corresponding endpoint returns a stall handshake to the host.

The EPOSTLC bit is used to clear the EPOSTLS stall setting. The EPOSTLC and EPOSTLS bits must not be set to 1 simultaneously.

The stall bit for endpoint 0 (EPOSTLS) is cleared automatically on reception of 8-bit command data to be decoded in this function module. When the SETUPTS flag in USBIFR1 is set, writing 1 to the EPOSTLS bit is ignored. For details, see section 24.7, Stall Operations.

USBEPSTL0 contains a write-only bit. The read value of such a bit is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

### 24.3.45 USB Endpoint Stall Register 1 (USBEPSTL1)

The bits in USBEPSTL1 are used to forcibly stall the endpoints on the application side. While a bit is set to 1, the corresponding endpoint returns a stall handshake to the host. Bits EP1STLC to EP3STLC are used to clear bits EP1STLS to EP3STLS. The stall setting bit and stall clear bit for the same endpoint must not be set to 1 simultaneously. For details, see section 24.7, Stall Operations.

USBEPSTL1 contains a write-only bit. The read value of such a bit is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

#### 24.3.46 USB Endpoint Stall Register 2 (USBEPSTL2)

The bits in USBEPSTL2 are used to forcibly stall the endpoints on the application side. While a bit is set to 1, the corresponding endpoint returns a stall handshake to the host. Bits EP4STLC to EP6STLC are used to clear bits EP4STLS to EP6STLS. The stall setting bit and stall clear bit for the same endpoint must not be set to 1 simultaneously. For details, see section 24.7, Stall Operations.

USBEPSTL2 contains a write-only bit. The read value of such a bit is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

#### 24.3.47 USB Endpoint Stall Register 3 (USBEPSTL3)

The bits in USBEPSTL3 are used to forcibly stall the endpoints on the application side. While a bit is set to 1, the corresponding endpoint returns a stall handshake to the host. Bits EP7STLC to EP9STLC are used to clear bits EP7STLS to EP9STLS. The stall setting bit and stall clear bit for the same endpoint must not be set to 1 simultaneously. For details, see section 24.7, Stall Operations.

USBEPSTL3 contains a write-only bit. The read value of such a bit is undefined. Do not write a value to this register using the read value, such as a bit manipulation instruction.

### 24.3.48 USB Stall Status Register 1 (USBSTLSR1)

Bits 0 to 2 in USBSTLSR1 indicate the internal stall status of endpoints 1 to 3. A value 1 shows stall status, and 0 shows normal status. These bits are status bits, and cannot be cleared. Bits 4 to 6 in USBSTLSR1 are automatic stall clear enable bits for endpoints 1 to 3.

|                |   |             |             |             |   |              |              |              |

### 24.3.51 USB DMA Transfer Setting Register (USBDMAR)

USBDMAR enables DMA or DTC transfer between the data registers for endpoints 1, 2, 4 and 5 and the memory by the on-chip direct memory access controller (DMAC) or on-chip data transfer controller (DTC). Dual-address transfer on a per-byte basis is performed. To start DMA transfer, DMAC settings must be made in addition to the settings in this register. For details of DMA transfer, see section 24.8, DMA Transfer. To start DTC transfer, DTC settings must be made in addition to the settings in this register. For details of DTC transfer, see section 24.9, DTC Transfer.

| 4      | EP5DMAE* | 0             | R/W | <p>EP5 DMA/DTC Transfer Enable</p> <p>When this bit is set, DMA/DTC transfer is enabled from the memory to the endpoint 5 transmit FIFO buffer. If there is at least one byte of space in the FIFO buffer, a transfer request is asserted to the DMAC or DTC. During DMA/DTC transfer, when 64 bytes are written to the FIFO buffer, the EP5 packet enable bit is set automatically, allowing 64 bytes of data to be transferred. If there is still space in the other of the two FIFO buffers, a transfer request is asserted to the DMAC or DTC again. However, if the size of the data packet to be transmitted is less than 64 bytes, the EP5 packet enable bit is not set automatically, and so should be set by the CPU with a DMA/DTC transfer end interrupt.</p> <p>Also, as EP5-related interrupt requests to the CPU are not automatically masked, interrupt requests should be masked as necessary in the USB interrupt enable register.</p> |

| 0   | EP5DMAE* | 0             | R/W | <p>EP1 DMA/DTC Transfer Enable</p> <p>When this bit is set, DMA/DTC transfer is enabled from the endpoint 1 receive FIFO buffer to the memory. If at least one byte of receive data is remaining in the FIFO buffer, a transfer request is asserted to the DMAC or DTC. During DMA/DTC transfer, when all the received data is read, an EP1 read completion trigger is given.</p> <p>Also, as EP1-related interrupt requests to the CPU are not automatically masked, interrupt requests should be masked as necessary in the USB interrupt enable register.</p> |

Note: \* To start DMA transfer, set the DME bit in DMAOR before setting this bit.  
 To start DTC transfer, set the corresponding DTCE bit in DTCER before setting this bit.

### 24.3.52 USB Configuration Value Register (USBCVR)

USBCVR stores Configuration Setting, Interface Setting, or Alternate Setting value that is set when the Set Configuration or Set Interface command is received successfully.

### 24.3.54 USB Endpoint Information Register (USBEPIR)

USBEPIR is used to set information of each endpoint, requiring five bytes per endpoint. Perform data write to this register sequentially beginning with logical endpoint 0. The total amount of write data should be within 50 bytes (5 bytes x 10 endpoints). Write endpoint information to this register once at a power-on reset, and do not write after that. Write data for an endpoint is described below.

Although there is one USBEPIR as data is written sequentially at the same address, the write data for endpoint 0 is shown as USBEPIR00 to USBEPIR04 (USBEPIR [endpoint number] [writing order]) for convenience of explanation. Write data to this register sequentially beginning with USBEPIR00. The read value is undefined.

|--------|----------|---------------|-----|----------------------------------------------------|
| 7 to 0 | D7 to D0 | —             | W   | Endpoint FIFO Number<br>[Settable range]<br>0 to 9 |

Endpoint numbers are used by the USB host. Endpoint FIFO numbers correspond to endpoint numbers appearing in this manual. Therefore, making endpoint numbers correspond to endpoint FIFO numbers one-to-one with this information allows data transfer between USB host and endpoint FIFO. However, note the following restrictions for settings.

Each endpoint FIFO is optimized by the dedicated hardware that meets the transfer method, transfer direction, and maximum packet size. Therefore, be sure to observe the settings for transfer method, transfer direction, and maximum packet size shown in table 24.3.

1. Ensure that endpoint 0 corresponds to endpoint FIFO number 0.
2. The maximum packet size for endpoint FIFO number 0 can be set to 16 only.
3. Only maximum packet size can be set for endpoint FIFO number 0, and the other bits are all 0.
4. The maximum packet size for endpoint FIFO numbers 1, 2, 4, 5, 7, and 8 can be set to 64 only.
5. Only "Bulk transfer" and "Out" can be set for endpoint FIFO numbers 1, 4, and 7.
6. Only "Bulk transfer" and "In" can be set for endpoint FIFO numbers 2, 5, and 8.
7. The maximum packet size for endpoint FIFO numbers 3, 6, and 9 can be set to 16 only.
8. Only "Interrupt transfer" and "In" can be set for endpoint FIFO numbers 3, 6, and 9.
9. Information for up to 10 endpoints can be set.
10. Information for 10 endpoints must be written.
11. Write all 0 for information of unused endpoints.

Table 24.3 lists the settable transfer method, transfer direction, and maximum packet size.

**Table 24.3 Restrictions for Settings**

| Endpoint FIFO Number | Maximum Packet Size | Transfer Method | Transfer Direction |
|----------------------|---------------------|-----------------|--------------------|
| 0                    | 16 bytes            | Control         | In/Out             |
| 1                    | 64 bytes            | Bulk            | Out                |

### 24.3.55 USB Transceiver Test Register 0 (USBTRNTREG0)

USBTRNTREG0 is a test register that controls the on-chip transceiver output signals. Setting PTSTE = 1 enables the transceiver output signals (USD+, USD-) to be set arbitrarily. Table 24.5 shows the USBTRNTREG0 setting and pin output state.

|                |       |   |   |   |             |       |       |        |
|----------------|-------|---|---|---|-------------|-------|-------|--------|

[Legend]

×: Don't care

—: Uncontrollable pin state in normal operation, depending on the USB operating status and port settings.

### 24.3.56 USB Transceiver Test Register 1 (USBTRNTREG1)

USBTRNTREG1 is a test register that monitors the on-chip transceiver input signals. Setting PTSTE = 1 and txenl = 1 in USBTRNTREG0 enables monitoring of the transceiver input signals. Table 24.6 shows pin input values and monitored USBTRNTREG1 values.

|                |   |   |   |   |   |           |      |      |
|----------------|---|---|---|---|---|-----------|------|------|

## 24.4 Interrupt Sources

This module has six interrupt signals. Table 24.7 shows interrupt sources and their corresponding interrupt request signals. USI0, USI1, USBRXI0, USBTXI0, USBRXI1, and USBTXI1 interrupt signals are active low. The USBINTN interrupt is detected only by level.

**Table 24.7 Interrupt Signals**

| Register | Bit | Transfer Mode          | Interrupt Source | Description                                | Interrupt Request Signal | DMAC/DTC Activation |

|          | 1   | Bulk_in transfer (EP5)      | EP5ALLEMP        | EP5FIFO all empty     | USI0 or USI1             | ×                   |
|          | 2   |                             | EP5EMPTY         | EP5FIFO empty         | USI0 or USI1             | USBTXI1             |
|          | 3   |                             | EP5TR            | EP5 transfer request  | USI0 or USI1             | ×                   |
|          | 4   | Interrupt_in transfer (EP6) | EP6TS            | EP6 transmit complete | USI0 or USI1             | ×                   |
|          | 5   |                             | EP6TR            | EP6 transfer request  | USI0 or USI1             | ×                   |
|          | 6   | —                           | Reserved         | —                     | —                        | —                   |
|          | 7   | —                           | Reserved         | —                     | —                        | —                   |
| USBIFR4  | 0   | Bulk_out transfer (EP7)     | EP7FULL          | EP7FIFO full          | USI0 or USI1             | ×                   |
|          | 1   | —                           | Reserved         | —                     | —                        | —                   |
|          | 2   | Bulk_in transfer (EP8)      | EP8EMPTY         | EP8FIFO empty         | USI0 or USI1             | ×                   |
|          | 3   |                             | EP8TR            | EP8 transfer request  | USI0 or USI1             | ×                   |
|          | 4   | Interrupt_in transfer (EP9) | EP9TS            | EP9 transmit complete | USI0 or USI1             | ×                   |
|          | 5   |                             | EP9TR            | EP9 transfer request  | USI0 or USI1             | ×                   |
|          | 6   | —                           | Reserved         | —                     | —                        | —                   |
|          | 7   | —                           | Reserved         | —                     | —                        | —                   |

Note: \* EP0-related interrupt sources must be assigned to the same interrupt request signal.

### **(1) USI0 signal**

The USI0 signal requests interrupts from the sources for which the corresponding bits in the interrupt select register 0, 1, 2, 3 or 4 (any of USBISR0 to USBISR4) are cleared to 0. This signal is asserted if any USB interrupt flag register bit that corresponds to the interrupt source assigned to this signal is set to 1.

### **(2) USI1 signal**

The USI1 signal requests interrupts from the sources for which the corresponding bits in the interrupt select register 0, 1, 2, 3 or 4 (any of USBISR0 to USBISR4) are set to 1. This signal is asserted if any USB interrupt flag register bit that corresponds to the interrupt source assigned to this signal is set to 1.

### **(3) USBRXI0 signal**

USBRXI0 is a DMAC/DTC activation interrupt signal only for EP1. For details, see section 24.8, DMA Transfer and section 24.9, DTC Transfer.

### **(4) USBTXI0 signal**

USBTXI0 is a DMAC/DTC activation interrupt signal only for EP2. For details, see section 24.8, DMA Transfer and section 24.9, DTC Transfer.

### **(5) USBRXI1 signal**

USBRXI1 is a DMAC/DTC activation interrupt signal only for EP4. For details, see section 24.8, DMA Transfer and section 24.9, DTC Transfer.

### **(6) USBTXI1 signal**

USBTXI1 is a DMAC/DTC activation interrupt signal only for EP5. For details, see section 24.8, DMA Transfer and section 24.9, DTC Transfer.

## 24.5 Operation

### 24.5.1 Initial Settings

**Figure 24.2 Initial Setting**

## 24.5.2 Cable Connection

**Figure 24.3 Cable Connection Operation**

The flowchart in figure 24.3 shows the operation in the case for section 24.10, Example of USB External Circuitry.

In applications that do not require USB cable connection to be detected, processing by the USB bus connection interrupt is not necessary. Preparations should be made with the bus reset interrupt.

### 24.5.3 Cable Disconnection

**Figure 24.4 Cable Disconnection Operation**

The flowchart in figure 24.4 shows the operation in the case for section 24.10, Example of USB External Circuitry.

### 24.5.4 Control Transfer

Control transfer consists of three stages: setup, data (not always included), and status as illustrated in figure 24.5. The data stage comprises a number of bus transactions. Operation flowcharts for each stage are shown below.

**Figure 24.5 Transfer Stages in Control Transfer**

**(1) Setup Stage****Figure 24.6 Setup Stage Operation**

## (2) Data Stage (Control-IN)

**Figure 24.7 Data Stage (Control-IN) Operation**

The application first analyzes command data from the host in the setup stage, and determines the subsequent data stage direction. If the result of command data analysis is that the data stage is in-transfer, one packet of data to be sent to the host is written to the FIFO. If there is more data to be sent, this data is written to the FIFO after the data written first has been sent to the host (USBIFR1.EP0iTS = 1).

The end of the data stage is identified when the host transmits an OUT token and the status stage is entered.

**Note:** If the size of the data transmitted by the function is smaller than the data size requested by the host, the function indicates the end of the data stage by returning to the host a packet shorter than the maximum packet size. If the size of the data transmitted by the function is an integral multiple of the maximum packet size, the function indicates the end of the data stage by transmitting a zero-length packet.

**(3) Data Stage (Control-OUT)****Figure 24.8 Data Stage (Control-OUT) Operation**

The application first analyzes command data from the host in the setup stage, and determines the subsequent data stage direction. If the result of command data analysis is that the data stage is OUT-transfer, the application waits for data from the host, and reads data from the FIFO after data is received (USBIFR1.EP0oTS = 1). Then the application writes 1 to the EP0o read complete bit, empties the receive FIFO, and waits for reception of the next data.

The end of the data stage is identified when the host transmits an IN token and the status stage is entered.

**(4) Status Stage (Control-IN)****Figure 24.9 Status Stage (Control-IN) Operation**

The control-IN status stage starts with an OUT token from the host. The application receives 0-byte data from the host, and ends control transfer.

**(5) Status Stage (Control-OUT)****Figure 24.10 Status Stage (Control-OUT) Operation**

The control-OUT status stage starts with an IN token from the host. When an IN token is received at the start of the status stage, there is not yet any data in the EP0i FIFO, and so an EP0i transfer request interrupt is generated. The application recognizes from this interrupt that the status stage has started. Next, in order to transmit 0-byte data to the host, 1 is written to the EP0i packet enable bit but no data is written to the EP0i FIFO. As a result, the next IN token causes 0-byte data to be transmitted to the host, and control transfer ends.

After the application has finished all processing relating to the data stage, 1 should be written to the EP0i packet enable bit.

### 24.5.5 EP1/EP4/EP7 Bulk-OUT Transfer

**Figure 24.11 EP1 Bulk-OUT Transfer Operation**

- Dual FIFOs (EP1, EP4)

EP1 (EP4) has two 64-byte FIFO buffers, but the user can receive data and read receive data without being aware of this dual-FIFO configuration.

When one FIFO is full after reception is completed, the EP1 (EP4) FULL bit in USBIFR2 (USBIFR3) is set to 1. After the first receive operation into one of the FIFOs when both FIFOs are empty, the other FIFO is empty and so the next packet can be received immediately. When both FIFOs are full, NAK is returned automatically to the host. When reading of the receive data is completed following data reception, 1 is written to the EP1 (EP4) RDFN bit in USBTRG1 (USBTRG2). This operation empties the FIFO that has just been read, and makes it ready to receive the next packet.

- Single FIFO (EP7)

EP7 has a single 64-byte FIFO buffer.

When the FIFO has received data, the EP7FULL bit in USBIFR4 is set to 1. When the FIFO is full, NAK is returned automatically to the host. When reading of the receive data is completed following data reception, 1 is written to the EP7RDFN bit in USBTRG3. This operation empties the FIFO that has just been read, and makes it ready to receive the next packet.

### 24.5.6 EP2/EP5/EP8 Bulk-IN Transfer

**Figure 24.12 EP2 Bulk-IN Transfer Operation**

- **Dual FIFOs (EP2, EP5)**

EP2 (EP5) has two 64-byte FIFO buffers, but the user can transmit data and write transmit data without being aware of this dual-FIFO configuration. However, one data write should be performed for one FIFO. For example, even if both FIFOs are empty, it is not possible to set the EP2 (EP5) PKTE bit to 1 at one time after consecutively writing 128 bytes of data. The EP2 (EP5) PKTE bit must be set for each 64-byte write.

When performing bulk-IN transfer, as there is no valid data in the FIFOs on reception of the first IN token, an EP2 (EP5) TR interrupt in USBIFR2 (USBIFR3) is requested. With this interrupt, 1 is written to the EP2 (EP5) EMPTYE bit in USBIER2 (USBIER3), and the EP2 (EP5) FIFO empty interrupt is enabled. At first, both EP2 (EP5) FIFOs are empty, and so an EP2 (EP5) FIFO empty interrupt is generated immediately.

The data to be transmitted is written to the data register using this interrupt. After the first transmit data write for one FIFO, the other FIFO is empty and so the next transmit data can be written immediately to the other FIFO. When both FIFOs are full, EP2 (EP5) EMPTYE is cleared to 0. If at least one FIFO is empty, the EP2 (EP5) EMPTYE bit in USBIFR2 (USBIFR3) is set to 1. When ACK is returned from the host after data transmission is completed, the FIFO that has transmitted data becomes empty. If the other FIFO contains valid transmit data at this time, transmission can be continued.

When transmission of all data has been completed, write 0 to the EP2 (EP5) EMPTYE bit in USBIER2 (USBIER3) to disable interrupt requests.

- Single FIFO (EP8)

EP8 has a single 64-byte FIFO buffer.

When performing bulk-IN transfer, as there is no valid data in the FIFO on reception of the first IN token, an EP8TR interrupt in USBIFR4 is requested. With this interrupt, 1 is written to the EP8EMPTYE bit in USBIER4, and the EP8 FIFO empty interrupt is enabled.

The data to be transmitted is written to the data register using this interrupt. When the FIFO is full, EP8EMPTYE is cleared to 0. When ACK is returned from the host after data transmission is completed, the FIFO that has transmitted data becomes empty and the EP8EMPTYE bit in USBIFR4 is set to 1.

When transmission of all data has been completed, write 0 to the EP8EMPTYE bit in USBIER4 to disable interrupt requests.

### 24.5.7 EP3/EP6/EP9 Interrupt-IN Transfer

**Figure 24.13 EP3 Interrupt-IN Transfer Operation**

## 24.6 Processing of USB Standard Commands and Class/Vendor Commands

### 24.6.1 Processing of Commands Transmitted by Control Transfer

A command transmitted from the host by control transfer may require decoding and execution of command processing on the application side. Commands that require or do not require decoding on the application side are listed in table 24.8 below.

**Table 24.8 Command Decoding on Application Side**

| <b>Decoding not Necessary on Application Side</b> | <b>Decoding Necessary on Application Side</b> |
|---------------------------------------------------|-----------------------------------------------|
| Clear Feature                                     | Get Descriptor                                |
| Get Configuration                                 | Class/Vendor commands                         |
| Get Interface                                     | Set Descriptor                                |
| Get Status                                        | Sync Frame                                    |
| Set Address                                       |                                               |
| Set Configuration                                 |                                               |
| Set Feature                                       |                                               |
| Set Interface                                     |                                               |

If decoding is not necessary on the application side, command decoding, data stage processing, and status stage processing are performed automatically. Therefore no processing is necessary for the user, and no interrupt is generated in this case.

If decoding is necessary on the application side, the USB function module stores the command in the EP0s FIFO. After normal reception is completed, the SETUPTS flag in USBIFR1 is set to 1 and an interrupt request is generated. In this interrupt routine, 8-byte data must be read from the USBEP0s data register (USBEPDR0s) and decoded by the firmware program. The necessary data stage and status stage processing should then be carried out according to the result of the decoding operation.

## 24.7 Stall Operations

### 24.7.1 Overview

This section describes stall operations in the USB function module. The USB function module stall function is used in the following cases:

- When the application forcibly stalls an endpoint for some reason
- When a stall is performed automatically within the USB function module due to a USB specification violation

The USB function module has internal status bits that hold the status (stall or non-stall) of each endpoint. When a transaction is sent from the host, the module references these internal status bits and determines whether to return a stall to the host. These bits cannot be cleared by the application. They must be cleared with a Clear Feature command from the host. The internal status bit for EP0 is automatically cleared only when the setup command is received.

### 24.7.2 Forcible Stall by Application

The application uses the USBEPSTL register to issue a stall request for the USB function module. When the application wishes to stall a specific endpoint, it sets the corresponding bit in USBEPSTL (1-1 in figure 24.14). The internal status bits remain unchanged at this time. When a transaction is sent from the host to the endpoint for which the USBEPSTL bit is set, the USB function module references the internal status bit, and if this is not set, references the corresponding bit in USBEPSTL (1-2 in figure 24.14). If the corresponding bit in USBEPSTL is set, the USB function module sets the internal status bit and returns a stall handshake to the host (1-3 in figure 24.14). If the corresponding bit in USBEPSTL is not set, the internal status bit remains unchanged and the transaction is accepted.

Once an internal status bit is set, it remains set until it is cleared by a Clear Feature command from the host, without regard to the USBEPSTL register. Even after a bit is cleared by the Clear Feature command (3-1 in figure 24.14), the USB function module continues to return a stall handshake while the bit in USBEPSTL is set, since the internal status bit is set each time a transaction is executed for the corresponding endpoint (1-2 in figure 24.14). To clear a stall, therefore, the corresponding bit in USBEPSTL must be cleared by the application, and the internal status bit must be cleared with a Clear Feature command (2-1, 2-2, and 2-3 in figure 24.14).

**Figure 24.14 Forcible Stall by Application**

### 24.7.3 Automatic Stall by USB Function Module

When a stall setting is made with a Set Feature command, or in the event of a USB specification violation, the USB function module automatically sets the internal status bit for the relevant endpoint regardless of the USBEPSTL register setting, and returns a stall handshake (1-1 in figure 24.15).

Once an internal status bit is set, it remains set until cleared by a Clear Feature command from the host regardless of the USBEPSTL register setting. After a bit is cleared by the Clear Feature command, USBEPSTL is referenced (3-1 in figure 24.15). The USB function module continues to return a stall handshake while the internal status bit is set to 1, since the internal status bit is set even if a transaction is executed for the corresponding endpoint (2-1 and 2-2 in figure 24.15). To clear a stall, therefore, the internal status bit must be cleared with a Clear Feature command (3-1 in figure 24.15). If set by the application, USBEPSTL should also be cleared (2-1 in figure 24.15).

**Figure 24.15 Automatic Stall by USB Function Module**

## 24.8 DMA Transfer

### 24.8.1 Overview

This module allows DMA transfer for endpoints 1, 2, 4, and 5, excluding transfer of word and longword. If endpoint 1 contains at least one byte of valid receive data, a DMA transfer request is issued to endpoint 1. If there is no valid data in endpoint 2, a DMA transfer request is issued to endpoint 2. If endpoint 4 contains at least one byte of valid receive data, a DMA transfer request is issued to endpoint 4. If there is no valid data in endpoint 5, a DMA transfer request is issued to endpoint 5.

When EP1DMAE or EP4DMAE in the USBDMA setting register is set to 1 to allow DMA transfer, 0-length data received for endpoint 1 or 4 is ignored. When DMA transfer is set, it is unnecessary to write 1 to the EP1RDFN, EP2PKTE, EP4RDFN, and EP5PKTE bits in USBTRG1 or USBTRG2. (However, the PKTE bit in USBTRG1 or USBTRG2 must be set to 1 for data with a size less than the maximum number of bytes.) For EP1 and EP4, the FIFO buffer automatically becomes empty when the received data has been completely read. For EP2 and EP5, the FIFO automatically becomes full when the maximum number of bytes (64 bytes) is written to the FIFO, allowing the data in the FIFO to be transmitted. (See figures 24.16 and 24.19.)

### 24.8.2 DMA Transfer for Endpoints 1 and 4

If the received data for EP1 is transferred by DMA, when the currently selected data FIFO becomes empty, processing equivalent to writing 1 to the EP1RDFN bit in USBTRG1 is automatically performed in the module. Therefore, do not write 1 to the EP1RDFN bit in USBTRG1 after reading the data on one side of the FIFO. If 1 is written to the EP1RDFN bit, correct operation cannot be guaranteed.

For example, if 150-byte data is received from the host, processing equivalent to writing 1 to the EP1RDFN bit in USBTRG1 is automatically performed internally in the three places in figure 24.16. Since this processing is performed when the data on the currently selected FIFO becomes empty, the processing is automatically performed in the same way even if data of 64 bytes or less is transferred.

Similarly, if the received data for EP4 is transferred by DMA, when the currently selected data FIFO becomes empty, processing equivalent to writing 1 to the EP4RDFN bit in USBTRG2 is automatically performed in the module. Therefore, do not write 1 to the EP4RDFN bit in USBTRG2 after reading the data on one side of the FIFO. If 1 is written to the EP4RDFN bit, correct operation cannot be guaranteed.

**Figure 24.16 EP1/EP4 RDFN (EP1RDFN, EP4RDFN) Operation**

**Figure 24.17 Example of DMA Transfer (Channel 0) for Bulk-OUT Transfer (EP1)  
(When Receive Data Size is Determined Before Receiving OUT Token)**

**Figure 24.18 Example of DMA Transfer (Channel 0) for Bulk-OUT Transfer (EP1)  
(When Receive Data Size Cannot be Determined Before Receiving OUT Token)**

### 24.8.3 DMA Transfer for Endpoints 2 and 5

If the transmitted data for EP2 is transferred by DMA, when the data on one side of FIFO (64 bytes) becomes full, processing equivalent to writing 1 to the EP2PKTE bit in USBTRG1 is automatically performed in the module. Therefore, when data to be transferred is a multiple of 64 bytes, writing 1 to the EP2PKTE bit in USBTRG1 is not necessary.

For data less than 64 bytes, a 1 should be written to the EP2PKTE bit in USBTRG1 by a DMA transfer end interrupt of the DMAC. If a 1 is written to the EP2PKTE bit for transferring the maximum number of bytes (64 bytes), the correct operation cannot be guaranteed.

For example, if 150-byte data is transmitted to the host, processing equivalent to writing 1 to the EP2PKTE bit in USBTRG1 is automatically performed internally in the two places in figure 24.19. Since this processing is performed when the data on the currently selected FIFO becomes full, the processing is automatically performed only when 64-byte data is transferred.

When the last 22 bytes have been transferred, write 1 to the EP2PKTE bit in USBTRG1 by the software because this is not automatically executed. There is no data to be transferred on the application side, but this module outputs the DMA transfer request for EP2 as long as the FIFO has a space. When the data has completely been transferred by DMA, write 0 to the EP2DMAE bit in USBDMAR to cancel the DMA transfer request for EP2.

Similarly, if the transmitted data for EP5 is transferred by DMA, when the data on one side of FIFO (64 bytes) becomes full, processing equivalent to writing 1 to the EP5PKTE bit in USBTRG2 is automatically performed in the module. Therefore, when data to be transferred is a multiple of 64 bytes, writing 1 to the EP5PKTE bit in USBTRG2 is not necessary. For data less than 64 bytes, a 1 should be written to the EP5PKTE bit in USBTRG2 by a DMA transfer end interrupt of the DMAC. If a 1 is written to the EP5PKTE bit for transferring the maximum number of bytes (64 bytes), the correct operation cannot be guaranteed.

**Figure 24.19 EP2/EP5 PKTE (EP2PKTE, EP5PKTE) Operation**

**Figure 24.20 Example of DMA Transfer (Channel 0) for Bulk-IN Transfer (EP2)  
(When Transmit Data Size is Determined Before Receiving IN Token)**

**Figure 24.21 Example of DMA Transfer (Channel 0) for Bulk-IN Transfer (EP2)  
(When Transmit Data Size Cannot be Determined Before Receiving IN Token)**

## 24.9 DTC Transfer

This module allows DTC transfer for endpoints 1, 2, 4, and 5, excluding transfer of word and longword. If endpoint 1 contains at least one byte of valid receive data, a DTC transfer request is issued to endpoint 1. If there is no valid data in endpoint 2, a DTC transfer request is issued to endpoint 2. If endpoint 4 contains at least one byte of valid receive data, a DTC transfer request is issued to endpoint 4. If there is no valid data in endpoint 5, a DTC transfer request is issued to endpoint 5.

When EP1DMAE or EP4DMAE in the USBDMA setting register is set to 1 to allow DTC transfer, 0-length data received for endpoint 1 or 4 is ignored. When DTC transfer is set, it is unnecessary to write 1 to the EP1RDFN, EP2PKTE, EP4RDFN, and EP5PKTE bits in USBTRG1 or USBTRG2. (However, the PKTE bit in USBTRG1 or USBTRG2 must be set to 1 for data with a size less than the maximum number of bytes.) For EP1 and EP4, the FIFO buffer automatically becomes empty when the received data has been completely read. For EP2 and EP5, the FIFO automatically becomes full when the maximum number of bytes (64 bytes) is written to the FIFO, allowing the data in the FIFO to be transmitted. (See figures 24.22 and 24.25.)

### 24.9.1 DTC Transfer for Endpoints 1 and 4

If the received data for EP1 is transferred by DTC, when the currently selected data FIFO becomes empty, processing equivalent to writing 1 to the EP1RDFN bit in USBTRG1 is automatically performed in the module. Therefore, do not write 1 to the EP1RDFN bit in USBTRG1 after reading the data on one side of the FIFO. If 1 is written to the EP1RDFN bit, correct operation cannot be guaranteed.

For example, if 150-byte data is received from the host, processing equivalent to writing 1 to the EP1RDFN bit in USBTRG1 is automatically performed internally in the three places in figure 24.22. Since this processing is performed when the data on the currently selected FIFO becomes empty, the processing is automatically performed in the same way even if data of 64 bytes or less is transferred.

Similarly, if the received data for EP4 is transferred by DTC, when the currently selected data FIFO becomes empty, processing equivalent to writing 1 to the EP4RDFN bit in USBTRG2 is automatically performed in the module. Therefore, do not write 1 to the EP4RDFN bit in USBTRG2 after reading the data on one side of the FIFO. If 1 is written to the EP4RDFN bit, correct operation cannot be guaranteed.

**Figure 24.22 EP1/EP4 RDFN (EP1RDFN, EP4RDFN) Operation**

**Figure 24.23 Example of DTC Transfer for Bulk-OUT Transfer (EP1)  
(When Receive Data Size is Determined Before Receiving OUT Token)**

**Figure 24.24 Example of DTC Transfer for Bulk-OUT Transfer (EP1)  
(When Receive Data Size Cannot be Determined Before Receiving OUT Token)**

## 24.9.2 DTC Transfer for Endpoints 2 and 5

If the transmitted data for EP2 is transferred by DTC, when the data on one side of FIFO (64 bytes) becomes full, processing equivalent to writing 1 to the EP2PKTE bit in USBTRG1 is automatically performed in the module. Therefore, when data to be transferred is a multiple of 64 bytes, writing 1 to the EP2PKTE bit in USBTRG1 is not necessary.

For data less than 64 bytes, a 1 should be written to the EP2PKTE bit in USBTRG1 by a DTC transfer end interrupt of the DTC. If a 1 is written to the EP2PKTE bit for transferring the maximum number of bytes (64 bytes), the correct operation cannot be guaranteed.

For example, if 150-byte data is transmitted to the host, processing equivalent to writing 1 to the EP2PKTE bit in USBTRG1 is automatically performed internally in the two places in figure 24.25. Since this processing is performed when the data on the currently selected FIFO becomes full, the processing is automatically performed only when 64-byte data is transferred.

When the last 22 bytes have been transferred, write 1 to the EP2PKTE bit in USBTRG1 by the software because this is not automatically executed. There is no data to be transferred on the application side, but this module outputs the DTC transfer request for EP2 as long as the FIFO has a space. When the data has completely been transferred by DTC, write 0 to the EP2DMAE bit in USBDMAR to cancel the DTC transfer request for EP2.

Similarly, if the transmitted data for EP5 is transferred by DTC, when the data on one side of FIFO (64 bytes) becomes full, processing equivalent to writing 1 to the EP5PKTE bit in USBTRG2 is automatically performed in the module. Therefore, when data to be transferred is a multiple of 64 bytes, writing 1 to the EP5PKTE bit in USBTRG2 is not necessary. For data less than 64 bytes, a 1 should be written to the EP5PKTE bit in USBTRG2 by a DTC transfer end interrupt of the DTC. If a 1 is written to the EP5PKTE bit for transferring the maximum number of bytes (64 bytes), the correct operation cannot be guaranteed.

(When Transmit Data Size Cannot be Determined Before Receiving IN Token)**

## 24.10 Example of USB External Circuitry

### (1) USD+ Pull-Up Control

In a system that wishes to delay USB host/hub connection notification (USD+ pull-up) (during high-priority processing or initialization processing, for example), USD+ pull-up should be controlled using a general output port. When the USB cable is already connected to the host or hub and USD+ pull-up is inhibited, the USD+ and USD− signals are driven low (these signals are pulled down on the host or hub side) and the USB module incorrectly recognizes that it has received the USB bus reset signal from the host. In that case, the USD+ pull-up control signal and VBUS pin input signal should be controlled using a general output port and the USB cable VBUS (AND circuit) as shown in figure 24.28. (The UDC core of this LSI holds the powered state while the VBUS pin level is low regardless of the USD+ and USD− state.)

### (2) Detection of USB Cable Connection/Disconnection

As USB states are managed by hardware in this module, a VBUS signal that recognizes USB cable connection/disconnection is necessary. The power supply signal (VBUS) in the USB cable is used for this purpose. However, if the cable is connected to the USB host or hub while the on-chip function LSI power is off, a voltage (5 V) will be applied from the USB host/hub. Therefore, an IC (HD74LV1G08A, 2G08A, etc.) that allows voltage application when the system power is off should be connected externally.

Note: This circuitry example does not guarantee the operation. When the system requires measures against external surge or ESD noise, implement measures with a compensation diode or noise canceler circuit.

**Figure 24.28 Example of USB Function Module External Circuitry**

## 24.11 Usage Notes

### 24.11.1 Receiving Setup Data

For USBEPDR0s that receives 8-byte setup data, note the following:

1. Since the USB always receives the setup command, writing from the USB bus has priority over reading from the CPU. When the USB starts receiving the next setup command while the CPU is reading data after data reception, the USB forcibly invalidates reading from the CPU to start writing. Therefore, the value that is read after starting reception is undefined.
2. USBEPDR0s must be read in 8-byte units. When reading is stopped in the middle, the data that is received by the next setup command cannot be read correctly.

### 24.11.2 Clearing FIFO

If the connected USB cable is disconnected during communication, the data being received or transmitted may remain in the FIFO. Therefore, clear the FIFO immediately after the USB cable is connected.

Do not clear the FIFO that is receiving data from or transmitting data to the host.

### 24.11.3 Overreading or Overwriting Data Registers

Note the following when reading or writing the data registers of this module:

#### (1) Receive Data Register

Do not read data that exceeds the valid receive data size from the receive data register. That is, data that exceeds the number of bytes specified in the receive data size register must not be read. For USBEPDR1 and USBEPDR4 that have two FIFOs, the maximum number of bytes that can be read at one time is 64 bytes. After reading data on the currently selected side, write 1 to the EPxRDFN bit in USBTRGx to change the current side to another side. This allows the number of bytes for the new side to be used as the receive data size, enabling the next data to be read.

## (2) Transmit Data Register

Do not write data that exceeds the maximum packet size to the transmit data register. For USBEPDR2 and USBEPDR5 that have two FIFOs, the data to be written at one time must be the maximum packet size or less. After writing data, write 1 to the EPxPKTE bit in USBTRGx to change the currently selected side to another in the module to allow the next data to be written to the new side. Therefore, do not write data to one side of FIFO right after the other side.

### 24.11.4 Assigning Interrupt Sources for EP0

Interrupt sources (bits 0 to 3) for EP0 that are assigned to USBIFR1 of this module must be assigned to the vector number of the same interrupt request using USBISR1. There are no restrictions on other interrupt sources.

### 24.11.5 Clearing FIFO when Setting DMAC/DTC Transfer

When DMA/DTC transfer is enabled (USBDMAR.EP1DMAE = 1 or EP4DMAE = 1) for endpoint 1 or 4, USBEPDR1 or USBEPDR4 cannot be cleared. To clear these registers, cancel DMA/DTC transfer.

### 24.11.6 Manual Reset for DMAC/DTC Transfer

Do not input a manual reset during DMA/DTC transfer for endpoints 1, 2, 4, and 5. Correct operation cannot be guaranteed.

### 24.11.7 USB Clock

Wait for the USB clock settling time and then cancel the module stop setting for the USB function module.

### 24.11.8 Using TR Interrupt

Note the following when using the transfer request interrupt (TR interrupt) for interrupt-IN transfer of EP0i/EP2/EP3/EP5/EP6/EP8/EP9.

The TR interrupt flag is set when an IN token is sent from the USB host and there is no data in the FIFO of the EP. However, TR interrupts occur continuously at the timing shown in figure 24.29. Make sure that no malfunction occurs in these cases.

Note: This module checks NAK acknowledgement if there is no data in the FIFO of the EP when receiving an IN token. However, the TR interrupt flag is set after the NAK handshake is transmitted. Therefore, when writing the PKTE bit in USBTRG is later than the next IN token, the TR interrupt flag is set again.

**Figure 24.29 Timing for Setting the TR Interrupt Flag**

### 24.11.9 Handling of Unused USB Pins

Handles the pins as listed below.

- $DrV_{cc} = V_{ccQ} = 3.0 \text{ to } 3.6 \text{ V}$
- $DrV_{ss} = 0 \text{ V}$
- $USD+ = \text{Open}$
- $USD- = \text{Open}$
- $VBUS = 0 \text{ V}$
- $USBEXTAL = 0 \text{ V}$
- $USBXTAL = \text{Open}$

## Section 25 Ethernet Controller (EtherC) (SH7216A, SH7214A, SH7216G, and SH7214G only)

This LSI has an on-chip Ethernet controller (EtherC) conforming to the Ethernet or the IEEE802.3 MAC (Media Access Control) layer standard. Connecting a physical-layer LSI (PHY-LSI) conforming to this standard enables the EtherC to transmit and receive Ethernet/IEEE802.3 frames. The EtherC has one MAC layer interface port. The EtherC is connected to the Ethernet Direct Memory Access Controller (E-DMAC) for Ethernet controller inside the LSI, and carries out high-speed data transfer to and from the memory.

Figure 25.1 shows a configuration of the EtherC.

### 25.1 Features

- Transmission and reception of Ethernet/IEEE802.3 frames
- Supports 10/100 Mbps data transfer
- Supports full-duplex and half-duplex modes
- Conforms to IEEE802.3u standard MII (Media Independent Interface)
- Magic Packet detection and Wake-On-LAN (WOL) signal output
- Conforms to IEEE802.3x flow control

**Figure 25.1 Configuration of EtherC**

## 25.2 Input/Output Pins

Table 25.1 lists the pin configuration of the EtherC.

**Table 25.1 Pin Configuration**

| Name                            | Abbreviation         | I/O    | Function                                                                    |
|---------------------------------|----------------------|--------|-----------------------------------------------------------------------------|
| Transmit clock*                 | TX-CLK               | Input  | TX-EN, MII_TXD3 to MII_TXD0, TX-ER timing reference signal                  |
| Receive clock*                  | RX-CLK               | Input  | RX-DV, MII_RXD3 to MII_RXD0, RX-ER timing reference signal                  |
| Transmit enable*                | TX-EN                | Output | Indicates that transmit data is ready on MII_TXD3 to MII_TXD0               |
| Transmit data*                  | MII_TXD3 to MII_TXD0 | Output | 4-bit transmit data                                                         |
| Transmit error*                 | TX-ER                | Output | Notifies PHY_LSI of error during transmission                               |
| Receive data valid*             | RX-DV                | Input  | Indicates that valid receive data is present on MII_RXD3 to MII_RXD0        |
| Receive data*                   | MII_RXD3 to MII_RXD0 | Input  | 4-bit receive data                                                          |
| Receive error*                  | RX-ER                | Input  | Identifies error state occurred during data reception                       |
| Carrier detection*              | CRS                  | Input  | Carrier detection signal                                                    |
| Collision detection*            | COL                  | Input  | Collision detection signal                                                  |
| Management data clock*          | MDC                  | Output | Reference clock signal for information transfer via MDIO                    |

### 25.3.1 EtherC Mode Register (ECMR)

ECMR is a 32-bit readable/writable register that specifies the operating mode of the EtherC. The settings of this register are normally made in the initialization process after a reset.

The operating mode setting must not be changed while the transmitting and receiving functions are enabled. To change the operating mode, return the EtherC and E-DMAC to their initial states with the SWR bit in EDMR of the E-DMAC before making settings again.

### 25.3.2 EtherC Status Register (ECSR)

ECSR is a 32-bit readable/writable register that indicates the status in the EtherC. This status can be notified to the CPU by interrupts. When 1 is written to the PSRTO, LCHNG, MPD, and ICD bits, the corresponding flags can be cleared to 0. Writing 0 does not affect any flags. For bits that generate interrupts, the interrupt can be enabled or disabled by the corresponding bit in ECSIPR.

The interrupts generated due to this status register are reflected in the ECI bit in EESR of the E-DMAC.

More specifically, this bit is set to 1 when the signals transmitted from the PHY-LSI to this LSI become RX-DV = 0, RX-ER = 1, and MII-RXD3 to MII-RXD0 = 1110 (see figure 25.4 (6)). If a change in the signal input from the PHY-LSI occurs in a period shorter than the software recognition period, correct information may not be obtained. Refer to the timing specification for the PHY-LSI used.<br><br>0: The PHY-LSI has not detected an illegal carrier on the line<br>1: The PHY-LSI has detected an illegal carrier on the line |

### 25.3.3 EtherC Interrupt Enable Register (ECSIPR)

ECSIPR is a 32-bit readable/writable register that enables or disables the interrupt sources indicated in ECSR. Each bit in ECSIPR can enable or disable interrupts corresponding to the bits in ECSR.

### 25.3.5 MAC Address High Register (MAHR)

MAHR is a 32-bit readable/writable register that specifies the upper 32 bits of 48-bit MAC address. This register is normally set in the initialization process after a reset. The MAC address setting must not be changed while the transmitting and receiving functions are enabled. Reset the EtherC and E-DMAC with the SWR bit in EDMR of the E-DMAC, and then set the MAC address again.

### 25.3.6 MAC Address Low Register (MALR)

MALR is a 32-bit readable/writable register that specifies the lower 16 bits of 48-bit MAC address. This register is normally set in the initialization process after a reset. The MAC address setting must not be changed while the transmitting and receiving functions are enabled. Reset the EtherC and E-DMAC with the SWR bit in EDMR of the E-DMAC, and then set the MAC address again.

## 25.3.7 Receive Frame Length Register (RFLR)

RFLR is a 32-bit readable/writable register that specifies the maximum frame length (in bytes) that can be received by this LSI. This register must not be modified while the receiving function is enabled.

|                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

25.3.9 Transmit Retry Over Counter Register (TROCR)

TROCR is a 32-bit counter that indicates the number of frames that were not transmitted in 16 transmission attempts including retransmission. When transmission fails 16 times, this register value is incremented by 1. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

| Bit     | Bit Name   | Initial Value | R/W | Description                                                                                                                                           |
|---------|------------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | TROC[31:0] | All 0         | R/W | Transmit Retry Over Count<br><br>These bits indicate the number of frames that were not transmitted in 16 transmission attempts including retransfer. |

### 25.3.10 Delayed Collision Detect Counter Register (CDCR)

CDCR is a 32-bit counter that indicates the number of all delayed collisions that occurred on the line from the beginning of data transmission. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

| Bit     | Bit Name    | Initial Value | R/W | Description                                                                                                |
|---------|-------------|---------------|-----|------------------------------------------------------------------------------------------------------------|
| 31 to 0 | COSDC[31:0] | All 0         | R/W | Delayed Collision Detect Count                                                                             |
|         |             |               |     | These bits indicate the number of all delayed collisions occurred from the beginning of data transmission. |

### 25.3.11 Lost Carrier Counter Register (LCCR)

LCCR is a 32-bit counter that indicates the number of times the carrier was lost during data transmission. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

|                |            |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|                | LCC[31:16] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

| 31 to 0 | LCC[31:0] | All 0         | R/W | Lost Carrier Count<br>These bits indicate the number of times the carrier was lost during data transmission. |

### 25.3.12 Carrier Not Detect Counter Register (CNDCR)

CNDCR is a 32-bit counter that indicates the number of times the carrier was not detected during transmission of the preamble. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|                | CNDC[31:16] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

|---------|------------|---------------|-----|-------------------------------------------------------------------------------------------------------|
| 31 to 0 | CNDC[31:0] | All 0         | R/W | Carrier Not Detect Count<br><br>These bits indicate the number of times the carrier was not detected. |

### 25.3.13 CRC Error Frame Receive Counter Register (CEFCR)

CEFCR is a 32-bit counter that indicates the number of times a frame with a CRC error was received. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|                | CEFC[31:16] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

| Bit     | Bit Name   | Initial Value | R/W | Description                                                                           |
|---------|------------|---------------|-----|---------------------------------------------------------------------------------------|
| 31 to 0 | CEFC[31:0] | All 0         | R/W | CRC Error Frame Count<br>These bits indicate the number of CRC error frames received. |

### 25.3.14 Frame Receive Error Counter Register (FRECR)

FRECR is a 32-bit counter that indicates the number of frames in which a receive error was generated by the RX-ER signal input from the PHY-LSI. FRECR is incremented each time the RX-ER pin becomes active. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

| Bit     | Bit Name    | Initial Value | R/W | Description                                                               |
|---------|-------------|---------------|-----|---------------------------------------------------------------------------|
| 31 to 0 | FRECR[31:0] | All 0         | R/W | Frame Receive Error Count                                                 |
|         |             |               |     | These bits indicate the number of errors occurred during frame reception. |

### 25.3.15 Too-Short Frame Receive Counter Register (TSFRCR)

TSFRCR is a 32-bit counter that indicates the number of frames received with a length of less than 64 bytes. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

|                |             |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31          | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|                | TSFC[31:16] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0           | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W         | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

  

|                |            |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15         | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                | TSFC[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

| Bit     | Bit Name   | Initial Value | R/W | Description                                                                                                            |
|---------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | TSFC[31:0] | All 0         | R/W | Too-Short Frame Receive Count<br><br>These bits indicate the number of too-short (less than 64 bytes) frames received. |

### 25.3.16 Too-Long Frame Receive Counter Register (TLFRCR)

TLFRCR is a 32-bit counter that indicates the number of frames received with a length exceeding the value specified by the receive frame length register (RFLR). When the value of this register reaches H'FFFFFFF, the counter stops incrementing. This register is not incremented when a frame containing residual bits is received. In this case, the reception of the frame is reflected in the residual-bit frame receive counter register (RFCR). The counter value is cleared to 0 by writing any value to this register.

| Bit     | Bit Name   | Initial Value | R/W | Description                                                                                                            |
|---------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | TLFC[31:0] | All 0         | R/W | Too-Long Frame Receive Count<br>These bits indicate the number of too-long (exceeding the RFLR value) frames received. |

### 25.3.17 Residual-Bit Frame Receive Counter (RFCR)

RFCR is a 32-bit counter that indicates the number of frames received containing residual bits (less than an 8-bit unit). When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

|                |            |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31         | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |
|                | RFC[31:16] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0          | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W        | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

|                |           |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15        | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                | RFC[15:0] |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0         | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

### 25.3.18 Multicast Address Frame Receive Counter Register (MAFCR)

MAFCR is a 32-bit counter that indicates the number of received frames that specify a multicast address. When the value of this register reaches H'FFFFFFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

### 25.3.19 IPG Register (IPGR)

IPGR is used to set an IPG (Inter Packet Gap) value. This register must not be modified while the transmitting and receiving functions of the EtherC mode register (ECMR) are enabled. (For details, see section 25.4.6, Operation by IPG Setting.)

### 25.3.20 Automatic PAUSE Frame Register (APR)

APR is used to set the TIME parameter value of an automatic PAUSE frame. When an automatic PAUSE frame is transmitted, the value set in this register is used as the TIME parameter of the PAUSE frame.

## 25.4 Operation

The following outlines the operations of the Ethernet controller (EtherC).

The EtherC supports control functions conforming to IEEE802.3x, allowing transmission/reception of PAUSE frames used for the control.

### 25.4.1 Transmission

The EtherC transmitter assembles transmit data into a frame and outputs it to the MII when a transmit request is made from the E-DMAC. The data transferred through the MII is output to the line by the PHY-LSI. Figure 25.2 illustrates state transitions of the EtherC transmitter.

**Figure 25.2 EtherC Transmitter State Transitions**

1. When the transmit enable (TE) bit is set to 1, the transmitter enters the idle state.
2. When a transmit request is issued by the transmit E-DMAC, the EtherC detects carrier and sends the preamble after a transmission delay equivalent to the frame interval time. If full-duplex transfer is selected, which does not require carrier detection, the preamble is sent as soon as a transmit request is issued by the E-DMAC.
3. The transmitter sends the SFD, data, and CRC sequentially. At the end of transmission, the transmit E-DMAC generates a transmission complete interrupt (TC). If a collision occurs or the carrier cannot be detected during data transmission, these events are reported as interrupt sources.
4. After the frame interval time has passed, the transmitter enters the idle state and continues to transmit data if there is more transmit data.

## 25.4.2 Reception

The EtherC receiver disassembles a frame sent from the MII into preamble, SFD, data, and CRC, and then transfers the fields from DA (destination address) to the CRC data to the receive E-DMAC. Figure 25.3 illustrates the state transitions of the EtherC receiver.

**Figure 25.3 EtherC Receiver State Transitions**

1. When the receive enable (RE) bit is set to 1, the receiver enters the idle state.
2. When the receiver detects an SFD (start frame delimiter) following the preamble in a receive packet, it starts receive processing. The receiver discards a frame with an invalid pattern.
3. In normal mode, if the destination address in a frame matches the address of this LSI, or if the frame is a broadcast frame or multicast frame, the receiver starts data reception. In promiscuous mode, the receiver starts data reception regardless of the frame type.
4. After receiving data from the MII, the receiver performs a CRC check. The check result is indicated as a status flag in the descriptor after the frame data has been written to the memory. The receiver reports an error status in the case of a CRC error.
5. After one frame has been received, if the receive enable bit is set ( $RE = 1$ ) in the EtherC mode register, the receiver prepares to receive the next frame.

### 25.4.3 MII Frame Timing

Each MII frame timing is shown in figure 25.4.

**Figure 25.4 (1) MII Frame Transmit Timing (Normal Transmission)**

**Figure 25.4 (2) MII Frame Transmit Timing (Collision)**

**Figure 25.4 (3) MII Frame Transmit Timing (Transmit Error)**

**Figure 25.4 (4) MII Frame Receive Timing (Normal Reception)**

**Figure 25.4 (5) MII Frame Receive Timing (Receive Error (1): Receive Error Notification)**

**Figure 25.4 (6) MII Frame Receive Timing (Receive Error (2): Carrier Error Notification)**

## 25.4.4 Accessing MII Registers

MI I registers in the PHY-LSI are accessed through the PHY interface register (PIR) in this LSI. Connection is made as a serial interface in accordance with the MII frame format specified in IEEE802.3u.

### (1) MII Management Frame Format

Figure 25.5 shows the format of an MII management frame. To access an MII register, a management frame is implemented by the program in accordance with the procedures shown in (2) MII Register Access Procedure.

| Access Type | MII Management Frame |    |    |       |       |    |      |      |
|-------------|----------------------|----|----|-------|-------|----|------|------|
| Item        | PRE                  | ST | OP | PHYAD | REGAD | TA | DATA | IDLE |
| Bits        | 32                   | 2  | 2  | 5     | 5     | 2  | 16   |      |
| Read        | 1..1                 | 01 | 10 | 00001 | RRRRR | Z0 | D..D |      |
| Write       | 1..1                 | 01 | 01 | 00001 | RRRRR | 10 | D..D | X    |

[Legend]

PRE: 32 consecutive 1s

ST: Write of 01 indicating start of frame

OP: Write of code indicating access type

PHYAD: Write of 0001 when the PHY-LSI address is 1 (sequential write starting with the MSB)  
The PHYAD bits vary with the PHY-LSI address.

REGAD: Write of 0001 when the register address is 1 (sequential write starting with the MSB)  
The REGAD bits vary with the PHY-LSI register address.

TA: Time for switching data transmission source on the MII interface  
(a) Write: 10 written

(b) Read: Bus release [notation: Z0] performed

DATA: 16-bit data. Sequential write or read starting with the MSB

(a) Write: 16-bit data write

(b) Read: 16-bit data read

IDLE: Wait time until next MII management format input

(a) Write: Independent bus release [notation: X] performed

(b) Read: Bus already released at TA (control unnecessary)

**Figure 25.5 MII Management Frame Format**

## (2) MII Register Access Procedure

The program accesses MII registers through the PHY interface register (PIR). An access is made by a combination of 1-bit-unit data write, 1-bit-unit data read, bus release, and independent bus release. Figure 25.6 shows the MII register access timing. The access timing differs depending on the PHY-LSI type.

**Figure 25.6 (1) 1-Bit Data Write Flow**

**Figure 25.6 (2) Bus Release Flow (TA in Read in Figure 25.5)****Figure 25.6 (3) 1-Bit Data Read Flow**

**Figure 25.6 (4) Independent Bus Release Flow (IDLE in Write in Figure 25.5)**

### 25.4.5 Magic Packet Detection

The EtherC has a Magic Packet detection function. This function provides a Wake-On-LAN (WOL) feature that activates various peripheral devices connected to a LAN from the host device or other source. This makes it possible to construct a system in which a peripheral device receives a Magic Packet sent from the host device or another source, and activates itself. When the Magic Packet is detected, data (such as the broadcast packets received previously) is stored in the receive FIFO and the EtherC is notified of the receiving status. To return to normal operation from the interrupt processing, initialize the EtherC and E-DMAC with the SWR bit in the E-DMAC mode register (EDMR).

Magic Packets are received regardless of the destination address. As a result, this function and the WOL pin are enabled only when the destination address matches the address specified by the format in the Magic Packet. Further information on Magic Packets is available in the technical documentation published by AMD Corporation.

The following setting procedure is necessary to use the WOL feature with this LSI.

1. Disable interrupt source output by means of the various interrupt enable/mask registers.
2. Set the Magic Packet detection enable (MPDE) bit in the EtherC mode register (ECMR).
3. Set the Magic Packet detection interrupt enable (MPDIP) bit in the EtherC interrupt enable register (ECSIPR) to 1.
4. If necessary, set the CPU operating mode to sleep mode or set peripheral modules to module standby mode.
5. When a Magic Packet is detected, an interrupt is sent to the CPU and the WOL pin notifies peripheral LSIs that the Magic Packet has been detected.

## 25.4.6 Operation by IPG Setting

The EtherC has a function to change the non-transmission period IPG (Inter Packet Gap) between transmit frames. By changing the set value of the IPG register (IPGR), the transmission efficiency can be raised and lowered from the standard value. IPG settings are prescribed in the IEEE802.3 standard. When changing IPG settings, adequately check that the respective devices can operate smoothly on the same network.

**Figure 25.7 Changing IPG and Transmission Efficiency**

## 25.4.7 Flow Control

The EtherC supports flow control functions conforming to IEEE802.3x for full-duplex operation. The flow control is available for both receive and transmit operations. When transmitting PAUSE frames, flow control can be performed in the following two procedures:

### (1) Transmitting Automatic PAUSE Frames

For receive frames, PAUSE frames are automatically transmitted when the volume of data written to the receive FIFO (in the E-DMAC) reaches the value set in the flow control start FIFO threshold setting register (FCFTR) in the E-DMAC. The TIME parameter contained in the PAUSE frame is set by the automatic PAUSE frame register (APR). The automatic PAUSE frame transmission is repeated until the volume of data in the receive FIFO becomes less than the FCFTR value as the receive data is read from the FIFO. The upper limit of PAUSE frame retransmission counts can also be set in the automatic PAUSE frame retransmit count register (TPAUSER). In this case, PAUSE frame transmission is repeated until the volume of receive FIFO data becomes less than the FCFTR value, or the transmit count reaches the TPAUSER value. Transmission of automatic PAUSE frames is enabled when the TXF bit in the EtherC mode register (ECMR) is 1.

### (2) Transmitting Manual PAUSE Frames

PAUSE frames are transmitted by software instructions. When a Timer value is written to the manual PAUSE frame register (MPR), manual PAUSE frame transmission is started. With this method, PAUSE frame transmission is carried out only once.

### (3) Receiving PAUSE Frames

After a PAUSE frame is received, the next frame is not transmitted until the time indicated by the Timer value elapses. However, the ongoing transmission of a frame is continued. Reception of PAUSE frames is enabled when the RXF bit in ECMR is set to 1.

## 25.5 Connection to the PHY-LSI

Figure 25.8 shows an example of connection to the RTL8201CP (Realtek Semiconductor Corp.).

**Figure 25.8 Example of Connection to RTL8201CP**

## 25.6 Usage Notes

Pay attention to the following when using the EtherC.

### (1) Conditions for setting the LCHNG bit

The LCHNG bit in ECSR may be set to 1 even when the LNKSTA pin input level remains unchanged. This may occur when the LNKSTA pin is selected by the PD19MD or PE0MD bits in the PFC or when a high level is input to the LNKSTA pin while the EtherC/E-DMAC software reset is canceled by the SWR bit in EDMR of the E-DMAC.

This is because the LNKSTA signal is internally fixed low regardless of the external pin input level when the LNKSTA pin is not selected by the PFC or while the EtherC/E-DMAC is in the software reset state.

In order not to generate a LINK signal change interrupt accidentally, clear the LCHNG bit to 0 and then set the LCHNGIP bit in ECSIPR.

To cause a transition to software standby mode, stop the EtherC/E-DMAC modules by setting the MSTP40 bit in the standby control register 4 (STBCR4) to 1.

### (2) Number of Cycles for Access to Registers

Note that the number of cycles for access to EtherC registers differs from the number for access to registers in other on-chip peripheral modules (see section 9.5.12 (3), On-Chip Peripheral Module Access).

## Section 26 Ethernet Controller Direct Memory Access Controller (E-DMAC) (SH7216A, SH7214A, SH7216G, and SH7214G only)

This LSI has an on-chip direct memory access controller (E-DMAC) directly connected to the Ethernet controller (EtherC). The E-DMAC controls the most part of the buffer management by using descriptors. This reduces the load on the CPU, thus enabling efficient data transmission/reception control.

Figure 26.1 shows the configuration of the E-DMAC and the descriptors and transmit/receive buffers in memory.

### 26.1 Features

- The load on the CPU is reduced by means of a descriptor management system.
- Transmit/receive frame status information is indicated in descriptors.
- Efficient system bus utilization is achieved through the use of DMA block transfer (32-byte units).
- Single-frame/multi-buffer operation is supported.

**Figure 26.1 Configuration of E-DMAC, Descriptors, and Buffers**

## 26.2 Register Descriptions

Table 26.1 shows the configuration of registers of the E-DMAC.

**Table 26.1 Register Configuration**

| <b>Name</b>                                        | <b>Abbreviation</b> | <b>R/W</b> | <b>Address</b> | <b>Access Size</b> |
|----------------------------------------------------|---------------------|------------|----------------|--------------------|
| E-DMAC mode register                               | EDMR                | R/W        | H'FFFC 3000    | 32                 |

## 26.2.1 E-DMAC Mode Register (EDMR)

EDMR is a 32-bit readable/writable register that specifies E-DMAC operating mode. This register should usually be set at initialization after a reset. If the EtherC and E-DMAC are initialized with this register during data transmission, abnormal data may be transmitted on the line. It is prohibited to modify the operating mode while the transmission or reception function is enabled. Before changing the operating mode, the EtherC and E-DMAC should be initialized by setting the software reset bit (SWR) to 1. Note that it takes 64 cycles of internal bus clock B $\phi$  for the EtherC and E-DMAC to be completely initialized. Therefore, the registers in the EtherC or E-DMAC should be accessed after that.

## 26.2.2 E-DMAC Transmit Request Register (EDTRR)

EDTRR is a 32-bit readable/writable register that issues transmit directives to the E-DMAC. After having transmitted one frame, the E-DMAC reads the next descriptor. When the TACT bit in this descriptor is set to 1 (valid), the E-DMAC continues transmission. Otherwise, the E-DMAC clears the TR bit and stops the transmit DMAC operation.

| 0       | TR       | 0             | R/W | Transmit Request<br>0: Transmission-halted state. Writing 0 does not stop transmission. Termination of transmission is controlled by the TACT bit of the transmit descriptor.<br>1: Transmission start. The relevant descriptor is read and the frame in which the TACT bit is 1 is transmitted. |

## 26.2.3 E-DMAC Receive Request Register (EDRRR)

EDRRR is a 32-bit readable/writable register that issues receive directives to the E-DMAC. After writing 1 to the RR bit in this register, the E-DMAC reads the receive descriptor. When the RACT bit in this receive descriptor is set to 1 (valid), the E-DMAC prepares for a receive request from the EtherC. When reception of data for the receive buffer is completed, the E-DMAC reads the next receive descriptor and prepares for receiving frames. If the RACT bit in the receive descriptor is cleared to 0 (invalid) at this time, the E-DMAC clears the RR bit and stops the receive DMAC operation.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                |
|---------|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------|
| 31 to 1 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                           |
| 0       | RR       | 0             | R/W | Receive Request<br>0: Receiving function is disabled*<br>1: Receive descriptor is read, and the E-DMAC is ready to receive |

**Note:** \* If the receiving function is disabled during frame reception, write-back is not performed successfully to the receive descriptor. Following pointers to read a receive descriptor become abnormal and the E-DMAC cannot operate successfully. In this case, to make E-DMAC reception enabled again, execute a software reset by the SWR bit in EDMR. To disable the E-DMAC receiving function without executing a software reset, clear the RE bit in ECMR of the EtherC to 0. Next, after the E-DMAC has completed the reception and write-back to the receive descriptor has been confirmed, disable the receiving function using this register.

## 26.2.4 Transmit Descriptor List Start Address Register (TDLAR)

TDLAR is a 32-bit readable/writable register that specifies the start address of the transmit descriptor list. Descriptors have a boundary configuration in accordance with the descriptor length indicated by the DL bits in EDMR. This register must not be modified during transmission, and must be modified while the TR bit in the E-DMAC transmit request register (EDTRR) is 0 (transmission-halted state).

## 26.2.5 Receive Descriptor List Start Address Register (RDLAR)

RDLAR is a 32-bit readable/writable register that specifies the start address of the receive descriptor list. Descriptors have a boundary configuration in accordance with the descriptor length indicated by the DL bits in EDMR. This register must not be modified during reception, and must be modified while the RR bit in the E-DMAC receive request register (EDRRR) is 0 (reception-disabled state).

## 26.2.6 EtherC/E-DMAC Status Register (EESR)

EESR is a 32-bit readable/writable register that indicates communications status information on the E-DMAC in combination with the EtherC. The information in this register is reported in the form of interrupt sources. Individual bits are cleared by writing 1 (except for read-only bit 22 (ECI)), and are not affected by writing 0. Each interrupt source can be masked by the corresponding bit in the EtherC/E-DMAC status interrupt enable register (EESIPR).

## 26.2.7 EtherC/E-DMAC Status Interrupt Enable Register (EESIPR)

EESIPR is a 32-bit readable/writable register that enables interrupts corresponding to individual bits in the EtherC/E-DMAC status register (EESR). An interrupt is enabled by writing 1 to the corresponding bit.

## 26.2.8 Transmit/Receive Status Copy Enable Register (TRSCER)

TRSCER specifies whether to reflect the transmit/receive status information reported by bits in the EtherC/E-DMAC status register (EESR) in bits TFS25 to TFS0 or RFS26 to RFS0 of the corresponding descriptor. The bits in this register correspond to bits 11 to 0 in EESR. When a bit is cleared to 0, the transmit status (bits 11 to 8 in EESR) is reflected in the TFS3 to TFS0 bits of the transmit descriptor, and the receive status (bits 7 to 0 in EESR) is reflected in the RFS7 to RFS0 bits of the receive descriptor. When a bit is set to 1, the occurrence of the corresponding source is not reflected in the descriptor. After this LSI is reset, all bits are cleared to 0.

## 26.2.9 Receive Missed-Frame Counter Register (RMFCR)

RMFCR is a 16-bit counter that indicates the number of frames that were not saved in the receive buffer and so were discarded during reception. When the receive FIFO overflows, the receive frames in the FIFO are discarded. The number of frames discarded at this time is counted. When the value in this register reaches H'FFFF, the counter stops incrementing. The counter value is cleared to 0 by writing any value to this register.

## 26.2.10 Transmit FIFO Threshold Register (TFTR)

TFTR is a 32-bit readable/writable register that specifies the transmit FIFO threshold at which the first transmission is started. The actual threshold is 4 times the set value. The EtherC starts transmission when the amount of data in the transmit FIFO exceeds the number of bytes specified by this register, when the transmit FIFO is full, or when one-frame data is written. Set this register in the transmission-halted state.

|         |           |         |     | H'201 to H'7FF: Setting prohibited                                                              |

- Notes:
1. When starting transmission before one-frame data write has been completed, take care no underflow occurs.
  2. Operation cannot be guaranteed when the value of this register is greater than the transmit FIFO or receive FIFO size.
  3. To prevent a transmit underflow, setting the initial value (store and forward mode) is recommended.

## 26.2.11 FIFO Depth Register (FDR)

FDR is a 32-bit readable/writable register that specifies the sizes of the transmit FIFO and receive FIFO.

**Note:** Operation cannot be guaranteed when the value set in this register is greater than the transmit FIFO or receive FIFO size.

## 26.2.12 Receiving Method Control Register (RMCR)

RMCR is a 32-bit readable/writable register that specifies how to control the RR bit in EDRRR when a frame is received. Set this register in the reception idle state.

|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | RNR      | 0             | R/W | <p>Receive Request Bit Reset</p> <p>0: Allows the hardware to reset the receive request (RR) bit in EDRRR automatically upon completion of reception of one frame.<br/>This control is possible for each frame.<br/>To receive the subsequent receive frame, the RR bit in EDRRR needs to be set again.</p> <p>1: Allows the higher-level software to control the receive request (RR) bit in EDRRR. Once the RR bit in EDRRR is set to 1, the hardware continues to fetch the receive descriptor and receive frames autonomously until the RR bit in EDRRR is cleared to 0. In other words, continuous reception of multiple frames are possible. Setting this bit to 1 is recommended for continuous reception. However, when a receive descriptor empty is detected, the hardware clears the RR bit in EDRRR automatically.</p> |

## 26.2.13 Transmit FIFO Underrun Counter Register (TFUCR)

TFUCR is a register that indicates the number of underruns having occurred in the transmit FIFO. The counter is cleared to 0 by writing any value to this register.

## 26.2.14 Receive FIFO Overflow Counter Register (RFOCR)

RFOCR is a register that indicates the number of overflows having occurred in the receive FIFO. The counter is cleared to 0 by writing any value to this register.

## 26.2.15 Receive Buffer Write Address Register (RBWAR)

RBWAR stores the buffer address of data to be written in the receive buffer when the E-DMAC writes data to the receive buffer. Which addresses in the receive buffer are processed by the E-DMAC can be recognized by monitoring the address specified in this register. The address that the E-DMAC is actually accessing during the buffer write processing is not always equal to the value read from this register.

## 26.2.16 Receive Descriptor Fetch Address Register (RDFAR)

RDFAR stores the descriptor start address required when the E-DMAC fetches descriptor information from the receive descriptor. Which receive descriptor information is used for processing by the E-DMAC can be recognized by monitoring the addresses indicated by this register. The address that the E-DMAC is actually accessing during the descriptor fetch processing is not always equal to the value read from this register.

## 26.2.19 Flow Control Start FIFO Threshold Setting Register (FCFTR)

FCFTR is a 32-bit readable/writable register that sets the flow control of the EtherC (automatic PAUSE transmission threshold setting). FCFTR can set the threshold values for the receive FIFO data size (RFDO[2:0]) and the number of receive frames (RFFO[2:0]). The flow control starts when either the receive FIFO data size threshold or the receive frame count threshold is determined.

If the same receive FIFO size as set by the FIFO depth register (FDR) is set when the flow control is to be turned on according to the RFDO setting condition, flow control is turned on with (FIFO data size – 64) bytes. When RFD = 00111 in FDR and RFDO = 111 in this register, for instance, the flow control is turned on when (2,048 – 64) bytes of data are stored in the receive FIFO. Set a value equal to or less than the RFD value in FDR for the RFDO bits in this register.

## 26.2.20 Transmit Interrupt Setting Register (TRIMD)

TRIMD is a 32-bit readable/writable register that specifies whether to notify write-back completion of each frame during transmission with the TWB bit in EESR or an interrupt.

## 26.2.21 Independent Output Signal Setting Register (IOSR)

The ELB bit value in this register is directly output to the general external output pin (EXOUT) of this LSI. The EXOUT pin can be used to specify loopback mode for the PHY-LSI. To achieve the loopback function for the PHY-LSI with this register, the PHY-LSI must have a pin corresponding to the EXOUT pin.

## 26.3 Operation

The E-DMAC, connected to the EtherC, allows efficient transfer of transmit/receive data between the EtherC and memory (buffers) without CPU intervention. The E-DMAC automatically reads the control information referred to as descriptors. The descriptors corresponding to each buffer store buffer pointers and other information. The E-DMAC reads transmit data from the transmit buffer and writes receive data to the receive buffer according to the control information. Arranging such multiple descriptors in a row (i.e., making a descriptor list) allows continuous transmission or reception.

### 26.3.1 Descriptor Lists and Data Buffers

The communication program creates a transmit descriptor list and a receive descriptor list in a memory space prior to transmission and reception, and sets the start addresses of these lists to the transmit descriptor list start address register and receive descriptor list start address register.

The start addresses of the descriptor lists should be placed on the address boundaries in accordance with the descriptor length specified by the E-DMAC mode register (EDMR). The start address of the transmit buffer can be placed on a longword, word, or byte boundary.

#### (1) Transmit Descriptor

Figure 26.2 shows the relationship between a transmit descriptor and a transmit buffer. The descriptor can relate one transmit frame to one transmit buffer (single-frame/single-buffer operation) or multiple transmit buffers (single-frame/multi-buffer operation).

When the transmit buffer length (TBL) is to be set to 1 to 16 bytes, the buffer address needs to be placed on a 32-byte boundary. When the transmit buffer length (TBL) is set below 42 bytes, operation cannot be guaranteed.

**Figure 26.2 Relationship between Transmit Descriptor and Transmit Buffer**

## (a) Transmit Descriptor 0 (TD0)

TD0 indicates the transmit frame status informing frame transmission status.

(The underlined bits in the table below are subject to write-back.)

| Bit       | Bit Name    | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**(b) Transmit Descriptor 1 (TD1)**

TD1 indicates the length of the transmit buffer.

| Bit      | Bit Name | Initial Value | R/W | Description                                                                                    |
|----------|----------|---------------|-----|------------------------------------------------------------------------------------------------|
| 31 to 16 | TBL      | All 0         | R/W | Transmit Buffer Length<br>Indicates the length of valid bytes of the relevant transmit buffer. |
| 15 to 0  | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.               |

**(c) Transmit Descriptor 2 (TD2)**

TD2 indicates the start address of the relevant transmit buffer.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                    |
|---------|----------|---------------|-----|--------------------------------------------------------------------------------|
| 31 to 0 | TBA      | All 0         | R/W | Transmit Buffer Address<br>Indicates the start address of the transmit buffer. |

## (2) Receive Descriptor

Figure 26.3 shows the relationship between a receive descriptor and a receive buffer. The receive buffer address should be set on a 32-byte boundary.

When the receive buffer length (RBL) is set to 0 byte, operation specified by the descriptor cannot be guaranteed.

**Figure 26.3 Relationship between Receive Descriptor and Receive Buffer**

## (a) Receive Descriptor 0 (RD0)

RD0 indicates the receive frame status informing frame reception status.

(The underlined bits in the table below are subject to write-back.)

| Bit           | Bit Name        | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

(For RFS7 to RFS0, it is possible to prevent this bit from being set by TRSCER. This is not possible, however, if a source indicated by RFS7 to RFS0 also causes RFS8 to be set.)                                                                                                                                                                                                                                                                                    |

| Bit            | Bit Name   | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

(Although RFE is normally set when these bits are set to 1, it can be prevented from being set by so setting TRSCER.)</p> |

**(b) Receive Descriptor 1 (RD1)**

RD1 indicates the length of the receive buffer.

(The underlined bits in the table below are subject to write-back.)

| Bit            | Bit Name   | Initial Value | R/W | Description                                                                                                                                     |
|----------------|------------|---------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 16       | RBL        | All 0         | R/W | Receive Buffer Length<br>Indicates the length of bytes of the relevant receive buffer.<br>A multiple of 32 should be set for the buffer length. |
| <u>15 to 0</u> | <u>RFL</u> | All 0         | R/W | Receive Frame Length<br>Indicates the length (number of bytes) of a receive frame stored in the buffer.                                         |

**(c) Receive Descriptor 2 (RD2)**

RD2 indicates the start address of the relevant receive buffer.

| Bit     | Bit Name | Initial Value | R/W | Description                                                                                                                             |
|---------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | RBA      | All 0         | R/W | Receive Buffer Address<br>Indicates the start address of the receive buffer.<br>The buffer address should be set on a 32-byte boundary. |

## 26.3.2 Transmission

When the transmit request bit (TR) in the E-DMAC transmit request register (EDTRR) is set while the transmission function is enabled, the E-DMAC reads the descriptor following the previously used descriptor from the transmit descriptor list (or the descriptor indicated by the transmit descriptor start address register (TDLAR) in the initial state). When the TACT bit of the read descriptor is set to 1 (valid), the E-DMAC reads transmit frame data sequentially from the transmit buffer start address specified by TD2 for transfer to the EtherC. The EtherC creates a transmit frame and starts transmission to the MII. After DMA transfer of data equivalent to the buffer length specified in the descriptor, the following processing is carried out according to the TFP value.

- TFP = 00 or 10 (frame continuation):  
Descriptor write-back (TACT bit only) is performed after DMA transfer.
- TFP = 01 or 11 (frame end):  
Descriptor write-back (TACT bit and status) is performed upon completion of frame transmission.

As long as the TACT bit of a read descriptor is set to 1 (valid), the reading of E-DMAC descriptors and the transmission of frames continue. When a descriptor with the TACT bit cleared to 0 (invalid) is read, the E-DMAC clears the TR bit in EDTRR to 0 and completes transmit processing.

**Figure 26.4 Example of Transmission Flow**

### 26.3.3 Reception

When the CPU sets the receive request bit (RR) in the E-DMAC receive request register (EDRRR) while the receive function is enabled, the E-DMAC reads the descriptor following the previously used descriptor from the receive descriptor list (or the descriptor indicated by the receive descriptor start address register (RDLAR) in the initial state), and then enters the receiving standby state. Upon receiving a frame for own station while the RACT bit is set to 1 (valid), the E-DMAC transfers the frame to the receive buffer specified by RD2. If the data length of a received frame is longer than the buffer length specified by RD1, the E-DMAC performs a write-back operation to the descriptor (with RFP set to 10 or 00) when the buffer becomes full, and then reads the next descriptor. The E-DMAC continues to transfer data to the receive buffer specified by the new RD2. When frame reception is completed, or if frame reception is suspended because of a certain kind of error, the E-DMAC performs write-back to the relevant descriptor (with RFP set to 11 or 01), and then ends the receive processing. The E-DMAC then reads the next descriptor and enters the receiving standby state again.

To receive frames continuously, the RNC bit in the receiving method control register (RMCR) must be set to 1. The initial value of the RNC bit is 0.

**Figure 26.5 Example of Reception Flow**

## 26.3.4 Transmit/Receive Processing of Multi-Buffer Frame

### (1) Multi-Buffer Frame Transmit Processing

If an error occurs during multi-buffer frame transmission, the E-DMAC performs the processing shown in figure 26.6.

In the figure where the transmit descriptor is shown as inactive (TACT bit = 0), buffer data has already been transmitted normally, and where the transmit descriptor is shown as active (TACT bit = 1), buffer data has not been transmitted. If a frame transmit error occurs in the first descriptor part where the transmit descriptor is active (TACT bit = 1), transmission is halted and the TACT bit is cleared to 0 immediately. The next descriptor is then read, and the position within the transmit frame is determined on the basis of bits TFP1 and TFP0 (continuing [B'00] or end [B'01]). In the case of a continuing descriptor, the TACT bit is cleared to 0 only, and the next descriptor is read immediately. If the descriptor is the final descriptor, the TACT bit is cleared to 0 and write-back is also performed to the TFE and TFS bits at the same time. Data in the buffer is not transmitted during a period from the occurrence of an error until the write-back to the final descriptor. If error interrupts are enabled in the EtherC/E-DMAC status interrupt enable register (EESIPR), an interrupt is generated immediately after the final descriptor write-back.

Figure 26.6 E-DMAC Operation after Transmit Error

## (2) Multi-Buffer Frame Receive Processing

If an error occurs during reception of a multi-buffer frame, the E-DMAC performs the processing shown in figure 26.7.

In the figure, the invalid receive descriptors (RACT = 0) represent the normal reception of buffer data, and the valid receive descriptors (RACT = 1) represent unreceived buffers. If a frame receive error occurs in the first descriptor part where the RCAT bit is set to 1, the status is written back to the descriptor.

If error interrupts are enabled in the EtherC/E-DMAC status interrupt enable register (EESIPR), an interrupt is generated immediately after the write-back. If there is a new frame receive request, reception is continued from the buffer after that in which the error occurred.

Figure 26.7 E-DMAC Operation after Receive Error

## 26.4 Usage Notes

### (1) Number of Cycles for Access to Registers

Note that the number of cycles for access to E-DMAC registers differs from the number for access to registers in other on-chip peripheral modules (see section 9.5.12 (3), On-Chip Peripheral Module Access).

## Section 27 Flash Memory (ROM)

The SH7214 and SH7216 Groups incorporate up to 1 Mbyte of flash memory (ROM) for the storage of instruction code. The ROM has the following features.

### 27.1 Features

- Two types of flash-memory MATs

The ROM has two types of memory areas (hereafter referred to as memory MATs) in the same address space. These two MATs can be switched by the start-up mode or bank switching through the control register. For addresses H'00008000 to H'000FFFFF, undefined data is read and programming and erasing are ignored when the user boot MAT is selected.

User MAT: 1 Mbyte (SH72167, SH72147)

: 768 Kbytes (SH72166, SH72146)

: 512 Kbytes (SH72165, SH72145)

User boot MAT: 32 Kbytes

**Figure 27.1 Memory MAT Configuration in ROM**

- High-speed reading through ROM cache

Both the user MAT and user boot MAT can be read at high speed through the ROM cache. They can be read only in on-chip ROM enabled mode.

- Programming and erasing methods

The ROM can be programmed and erased by commands issued through the peripheral bus (P bus) to the ROM/data flash (FLD) dedicated sequencer (FCU).

While the flash control unit (FCU) is programming or erasing the ROM, the CPU can execute a program located outside the ROM. While the FCU is programming or erasing the FLD, the CPU can execute a program in the ROM. When the FCU suspends programming or erasure, the CPU can execute a program in the ROM, and then the FCU can resume programming or erasure. While the FCU suspends erasure, areas other than the erasure-suspended area can be programmed.

Figure 27.2 Block Diagram of ROM

- Programming/erasing unit

The user MAT and user boot MAT are programmed in 256-byte units. The entire area of the user boot MAT is always erased at one time. The user MAT can be erased in block units if the mode is not programmer mode. The entire area of the user MAT is erased in programmer mode.

Figure 27.3 shows the block configuration of the user MAT. The user MAT is divided into eight 8-Kbyte blocks, nine 64-Kbyte blocks, and three 128-Kbyte blocks.

**Figure 27.3 Block Configuration of User MAT**

- Four types of on-board programming modes
  - Boot mode

The user MAT and user boot MAT can be programmed using the SCI. The bit rate for SCI communications between the host and this LSI can be automatically adjusted.
  - USB boot mode

The user MAT and user boot MAT can be programmed in program mode using the USB.
  - User program mode

The user MAT can be programmed with a desired interface. A transition from MCU mode 2 (MCU extended mode) or mode 3 (MCU single-chip mode) to this mode is enabled simply by changing the level on the FWE pin.
  - User boot mode

The user MAT can be programmed with a desired interface. To make a transition to this mode, a reset is needed.
- One type of off-board programming mode
  - Programmer mode

The user MAT and user boot MAT can be programmed in programmer mode using the PROM programmer.
- Protection modes

This LSI supports two modes to protect memory against programming or erasure: hardware protection by the levels on the FWE and mode pins and software protection by the FENTRY0 bit in FENTRYR or lock bit settings. The FENTRY0 bit enables or disables ROM programming or erasure by the FCU. A lock bit is included in each erasure block of the user MAT to protect memory against programming or erasure.

The LSI also provides a function to suspend programming or erasure when abnormal operation is detected during programming or erasure.
- Programming and erasing time and count

Refer to section 33, Electrical Characteristics.

## 27.2 Input/Output Pins

Table 27.1 shows the input/output pins used for the ROM. The combination of MD1 and MD0 pin levels and the FWE pin level determines the ROM programming mode (see section 27.4, Overview of ROM-Related Modes). In boot mode, the ROM can be programmed or erased by the host connected via the PA3/RxD1 and PA4/TxD1 pins (see section 27.5, Boot Mode).

**Table 27.1 Pin Configuration**

| Pin Name                       | Symbol                  | I/O    | Function                                                                      |
|--------------------------------|-------------------------|--------|-------------------------------------------------------------------------------|
| Power-on reset                 | $\overline{\text{RES}}$ | Input  | This LSI enters the power-on reset state when this signal goes low.           |
| Mode                           | MD1, MD0                | Input  | These pins specify the operating mode.                                        |
| Flash programming enable       | FWE                     | Input  | This pin enables or disables ROM programming.                                 |
| Receive data in SCI channel 1  | PA3/RxD1                | Input  | Receives data through SCI channel 1 (communications with host)                |
| Transmit data in SCI channel 1 | PA4/TxD1                | Output | Transmits data through SCI channel 1 (communications with host)               |
| Pull-up control                | PUPD (PB15)             | Output | Pull-up control (used in USB boot mode)                                       |
| USB data                       | USD+<br>USD-            | I/O    | USD signal from the USB that has a transceiver (used in USB boot mode)        |
| USB cable connection monitor   | VBUS                    | Input  | Detects connection and disconnection of the USB cable (used in USB boot mode) |
| USB clock select               | PB14                    | Input  | Selects the clock supplied by the USB (used in USB boot mode)                 |

## 27.3 Register Descriptions

Table 27.2 shows the ROM-related registers. Some of these registers have data flash (FLD) related bits, but this section only describes the ROM-related bits. For the FLD-related bits, refer to section 28.3, Register Descriptions. The ROM-related registers are initialized by a power-on reset.

**Table 27.2 Register Configuration**

| Register Name                                | Symbol  | R/W* <sup>1</sup>   | Initial Value        | Address    | Access Size |
|----------------------------------------------|---------|---------------------|----------------------|------------|-------------|
| Flash pin monitor register                   | FPMON   | R                   | H'00<br>H'80         | H'FFFFA800 | 8           |
| Flash mode register                          | FMODR   | R/W                 | H'00                 | H'FFFFA802 | 8           |

| Flash access error interrupt enable register | FAEINT  | R/W                 | H'9F                 | H'FFFFA811 | 8           |
| ROM MAT select register                      | ROMMAT  | R/(W)* <sup>3</sup> | H'0000<br>H'0001     | H'FFFFA820 | 8, 16       |
| FCU RAM enable register                      | FCURAME | R/(W)* <sup>3</sup> | H'0000               | H'FFFFA854 | 8, 16       |
| Flash status register 0                      | FSTATR0 | R                   | H'80* <sup>5</sup>   | H'FFFFA900 | 8, 16       |
| Flash status register 1                      | FSTATR1 | R                   | H'00* <sup>5</sup>   | H'FFFFA901 | 8, 16       |
| Flash P/E mode entry register                | FENTRYR | R/(W)* <sup>4</sup> | H'0000* <sup>5</sup> | H'FFFFA902 | 8, 16       |
| Flash protect register                       | FPROTR  | R/(W)* <sup>4</sup> | H'0000* <sup>5</sup> | H'FFFFA904 | 8, 16       |
| Flash reset register                         | FRESETR | R/(W)* <sup>3</sup> | H'0000               | H'FFFFA906 | 8, 16       |
| FCU command register                         | FCMDR   | R                   | H'FFFF* <sup>5</sup> | H'FFFFA90A | 8, 16       |
| FCU processing switch register               | FCPSR   | R/W                 | H'0000* <sup>5</sup> | H'FFFFA918 | 8, 16       |
| Flash P/E status register                    | FPESTAT | R                   | H'0000* <sup>5</sup> | H'FFFFA91C | 8, 16       |
| ROM cache control register                   | RCCR    | R/W                 | H'00000001           | H'FFFC1400 | 32          |
| Peripheral clock notification register       | PCKAR   | R/W                 | H'0000* <sup>5</sup> | H'FFFFA938 | 8, 16       |

- Notes:
1. In on-chip ROM disabled mode, the ROM-related registers are always read as 0 and writing to them is ignored.
  2. This register consists of the bits where only 0 can be written to clear the flags and the read-only bits.
  3. This register can be written to only when a specified value is written to the upper byte in word access. The data written to the upper byte is not stored in the register.

4. This register can be written to only when a specified value is written to the upper byte in word access; the register is initialized when a value not allowed for the register is written to the upper byte. The data written to the upper byte is not stored in the register.
5. These registers can be initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

### 27.3.1 Flash Pin Monitor Register (FPMON)

FPMON monitors the FWE pin state. FPMON is read as H'00 in on-chip ROM disabled mode. FPMON is initialized by a power-on reset.

### 27.3.2 Flash Mode Register (FMODR)

FMODR specifies the FCU operation mode. In on-chip ROM disabled mode, FMODR is read as H'00 and writing to it is ignored. FMODR is initialized by a power-on reset.

### 27.3.3 Flash Access Status Register (FASTAT)

FASTAT indicates the access error status for the ROM and FLD. In on-chip ROM disabled mode, FASTAT is read as H'00 and writing to it is ignored. If any bit in FASTAT is set to 1, the FCU enters command-locked state (see section 27.9.3, Error Protection). To cancel a command-locked state, set FASTAT to H'10, and then issue a status-clear command to the FCU. FASTAT is initialized by a power-on reset.

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 27.3.4 Flash Access Error Interrupt Enable Register (FAEINT)

FAEINT enables or disables output of flash interface error (FIFE) interrupts. In on-chip ROM disabled mode, FAEINT is read as H'00 and writing to it is ignored. FAEINT is initialized by a power-on reset.

### 27.3.8 Flash Status Register 1 (FSTATR1)

FSTATR1 indicates the FCU status. In on-chip ROM disabled mode, FSTATR1 is read as H'00. FSTATR1 is initialized by a power-on reset, or setting the FRESET bit of the FRESETR register is set to 1.

### 27.3.9 Flash P/E Mode Entry Register (FENTRYR)

FENTRYR specifies the P/E mode for the ROM or FLD. To specify the P/E mode for the ROM or FLD so that the FCU can accept commands, set either of FENTRYD and FENTRY0 bits to 1. In on-chip ROM disabled mode, FENTRYR is read as H'0000 and writing to it is ignored. FENTRYR can be initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

In access to the FENTRYR for a mode transition of the FCU, write to the register and then read it, and only proceed with programming, erasure or reading of the ROM after confirming the register setting.

### 27.3.10 Flash Protect Register (FPROTR)

FPROTR enables or disables the protection function through the lock bits against programming and erasure. In on-chip ROM disabled mode, FPROTR is read as H'0000 and writing to it is ignored. FPROTR is initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

### 27.3.11 Flash Reset Register (FRESETR)

FRESETR is used for the initialization of FCU. In on-chip ROM disabled mode, FRESETR is read as H'0000 and writing to it is ignored. FRESETR is initialized by a power-on reset.

| 0       | FRESET   | 0             | R/W    | Flash Reset<br><br>Setting this bit to 1 forcibly terminates programming/erasure of ROM or FLD and initializes the FCU. A high voltage is applied to the ROM/FLD memory units during programming and erasure. To ensure sufficient time for the voltage applied to the memory unit to drop, keep the value of the FRESET bit at 1 for a period of $t_{RESW2}$ (see section 33, Electrical Characteristics) when the FCU is initialized. Do not read from the ROM/FLD units while the value of the FRESET bit is kept at 1. The FCU commands are unavailable for use while the FRESET bit is set to 1, since this initializes the FENTRYR register. This bit can be written only when H'CC is written to FRKEY in word access.<br><br>0: Issue no reset to the FCU.<br>1: Issues a reset to the FCU. |

Note: \* Write data is not retained.

### 27.3.12 FCU Command Register (FCMDR)

FCMDR stores the commands that the FCU has accepted. In on-chip ROM disabled mode, FCMDR is read as H'0000 and writing to it is ignored. FCMDR is initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

|                |      |    |    |    |    |    |   |   |       |   |   |   |   |   |   |   |

| Peripheral clock notification                   | H'E9 | Previous command |

27.3.13 FCU Processing Switch Register (FCPSR)

FCPSR selects a function to make the FCU suspend erasure. In on-chip ROM enabled mode, FCPSR is read as H'0000 and writing to it is ignored. FCPSR is initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

### 27.3.14 Flash P/E Status Register (FPESTAT)

FPESTAT indicates the result of programming/erasure of the ROM/FLD. In on-chip ROM enabled mode, FPESTAT is read as H'0000 and writing to it is ignored. FPESTAT is initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

### 27.3.15 ROM Cache Control Register (RCCR)

RCCR contains the RCF bit that controls the disabling of all lines in the ROM cache.

This register can be accessed only in longwords.

### 27.3.16 Peripheral Clock Notification Register (PCKAR)

PCKAR is used to notify the sequencer of information regarding the frequency setting of the peripheral clock ( $P\phi$ ) for programming or erasure of the ROM or data flash memory. The setting governs the time programming or erasure takes. In modes where the internal ROM is disabled, the value read from the PCKAR will be H'0000 and writing to the PCKAR will be ineffective.

PCKAR is initialized by a power-on reset or by writing 1 to the FRESET bit in FRESETR.

| 7 to 0  | PCKA     | H'00          | R/W | Peripheral Clock Notification<br>These bits are used to notify the peripheral clock ( $P\phi$ ) for programming or erasure of the ROM or data flash memory. Set the frequency of $P\phi$ by setting these bits before programming or erasure, and then issue a peripheral clock notification command. Do not change the frequency while the ROM or data flash memory is being programmed or erased.<br>Follow the procedure below to calculate the setting. <ul style="list-style-type: none"> <li>Convert the frequency expressed in MHz units to binary notation, and write the value to the PCKA bits. For example, if the frequency of the peripheral clock is 35.9 MHz, the setting is derived as follows.</li> <li>Round 35.9 up to obtain 36.</li> <li>Convert 36 into binary form and set the PCKA bits to H'24 (B'00100100).</li> </ul> Notes: 1. Do not issue the command for overwriting the ROM or data flash memory if the setting of the PCKA bits is for a frequency outside the range from 20 to 50 MHz.<br>2. If the frequency set by the PCKA bits differs from the actual frequency, there is a possibility of destroying the ROM or data flash memory. |

## 27.4 Overview of ROM-Related Modes

Figure 27.4 shows the ROM-related mode transition in this LSI. For the relationship between the LSI operating modes and the MD1, MD0 and FWE pin settings, refer to section 3, MCU Operating Modes.

**Figure 27.4 ROM-Related Mode Transition**

- The ROM cannot be read, programmed, or erased in on-chip ROM disabled mode (MCU extended modes 0 and 1).
- The ROM can be read but cannot be programmed or erased in user mode (MCU extended mode 2 and single chip mode).
- The ROM can be read, programmed, and erased on the board in user program mode, user boot mode, boot mode, and USB boot mode.

Table 27.4 compares programming- and erasure-related items for the boot mode, user program mode, user boot mode, USB boot mode, and programmer mode.

**Table 27.4 Comparison of Programming Modes**

| Item                             | Boot Mode                                                                                                               | User Program Mode          | User Boot Mode                                                      | USB Boot Mode                                             | Programmer Mode             |

- Notes: 1. The entire area is erased when the LSI is started. After that, a specified block can be erased.
2. After the LSI is started in the embedded program stored MAT and the boot program provided by Renesas Corp. is executed, execution starts from the location indicated by the reset vector of the user boot MAT.

- The user boot MAT can be programmed or erased only in boot mode, USB boot mode, and programmer mode.
- In boot mode or USB boot mode, the user MAT, user boot MAT, and FLD data MAT are all erased immediately after the LSI is started. The user MAT, user boot MAT, and data MAT can then be programmed from the host via the SCI. The ROM can also be read after this entire area erasure.
- In user boot mode, a boot operation with a desired interface can be implemented through mode pin settings different from those in user program mode.

## 27.5 Boot Mode

### 27.5.1 System Configuration

To program or erase the user MAT and user boot MAT in boot mode, send control commands and programming data from the host. The on-chip SCI of this LSI is used in asynchronous mode for communications between the host and this LSI. The tool for sending control commands and programming data must be prepared in the host. When this LSI is started in boot mode, the program in the embedded program stored MAT is executed. This program automatically adjusts the SCI bit rate and performs communications between the host and this LSI by means of the control command method.

Figure 27.5 shows the system configuration in boot mode. The NMI and  $\overline{\text{IRQ7}}$  to  $\overline{\text{IRQ0}}$  interrupts are ignored in this mode, but these pins must be fixed to non-active state. Note that the AUD cannot be used in this mode.

**Figure 27.5 System Configuration in Boot Mode**

## 27.5.2 State Transition in Boot Mode

Figure 27.6 shows the state transition in boot mode.

**Figure 27.6 State Transition in Boot Mode**

### (1) Bit Rate Adjustment

After this LSI is started in boot mode, it automatically adjusts the bit rate for communications between the host and SCI. After automatic adjustment of the bit rate, the LSI sends H'00 to the host. After the LSI has successfully received H'55 sent from the host, the LSI waits for a host command for inquiry or selection. For details on bit rate adjustment, see section 27.5.3, Automatic Adjustment of Bit Rate.

## **(2) Waiting for Host Command for Inquiry or Selection**

In this state, the host inquires regarding MAT information (such as the size, configuration, and start address) and the supported functions, and selects the device, clock mode, and bit rate. Upon reception of a programming/erasure state transition command sent from the host, this LSI erases the entire area of each of the user MAT, user boot MAT, and FLD data MAT and waits for a host command for programming or erasure. For details of inquiry/selection host commands, see section 27.5.5, Inquiry/Selection Host Command Wait State.

## **(3) Waiting for Host Command for Programming or Erasure**

In this state, this LSI performs programming or erasure according to the command sent from the host. The LSI enters programming data wait state, erasure block specification wait state, or command (read or check) processing state depending on the received command.

Upon reception of a programming selection command, the LSI waits for programming data. After the programming selection command, send the programming start address and programming data from the host. Specifying H'FFFFFFF as the programming start address terminates programming processing and the LSI makes a transition from the programming data wait state to programming/erasure command wait state.

Upon reception of an erasure selection command, the LSI waits for erasure block specification. After the erasure selection command, send the erasure block number from the host. Specifying H'FF as the erasure block number terminates erasure processing and the LSI makes a transition from the erasure block specification wait state to programming/erasure command wait state. As the entire area of each of the user MAT, user boot MAT, and FLD data MAT is erased before the LSI enters programming/erasure command wait state after it is started in boot mode, erasure processing is not needed except for the case when the data programmed in boot mode should be erased without resetting the LSI.

In addition to programming and erasing commands, many other host commands are provided for use in programming/erasure command wait state; these include commands for checksum, blank check (erasure check), memory read, and status inquiry. For details on these host commands, see section 27.5.6, Programming/Erasing Host Command Wait State.

### 27.5.3 Automatic Adjustment of Bit Rate

When this LSI is started in boot mode, it measures the low-level (H'00) period of the data that is continuously sent from the host in asynchronous SCI communications. During this measurement, set the SCI transmit/receive format to 8-bit data, 1 stop bit, and no parity, and set the bit rate to 9,600 bps or 19,200 bps. This LSI calculates the bit rate of the host SCI by means of the measured low-level period, and then sends H'00 to the host after completing the bit rate adjustment. When the host has received H'00 successfully, it must send H'55 to this LSI. If the host has failed to receive H'00, restart this LSI in boot mode to calculate and adjust the bit rate again. When this LSI has received H'55, it returns H'E6 to the host, or when it has failed to receive H'55, it returns H'FF.

**Figure 27.7** SCI Transmit/Receive Format for Automatic Adjustment of Bit Rate

**Figure 27.8** Communication Sequence between Host and This LSI

The bit rate may not be adjusted correctly depending on the bit rate of the host SCI or the peripheral clock frequency of this LSI. Satisfy the SCI communications condition as shown in table 27.5.

**Table 27.5 Condition for Automatic Adjustment of Bit Rate**

| Host SCI Bit Rate | Peripheral Clock Frequency of this LSI |
|-------------------|----------------------------------------|
| 9,600 bps         | 20 to 50 MHz                           |
| 19,200 bps        | 20 to 50 MHz                           |

### 27.5.4 USB Boot Mode

USB boot mode is used to send control commands and programming data from the externally connected host via the USB to program and erase the user MAT and user boot MAT.

USB boot mode needs programming data on the host side and a tool to send control commands and programming data. Figure 27.9 shows the system configuration in USB boot mode. All interrupt requests generated in USB boot mode are ignored. No interrupt requests should be generated on the system side.

**Figure 27.9 System Configuration in USB Boot Mode**

## (1) Features

- Power mode: Self-powered mode
- The D+ pull-up control connection is supported only by the PUPD pin (PB15).
- For enumeration information, see table 27.6.

**Table 27.6 Enumeration Information**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| USB standard       | Ver. 2.0 (full-speed)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Transfer mode      | Transfer mode control (in, out), bulk (in, out)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Endpoint structure | EP0 Control (in, out) 16 bytes<br><br>Configuration 1 <ul style="list-style-type: none"> <li>└ InterfaceNumber 0               <ul style="list-style-type: none"> <li>└ AlternateSetting 0                   <ul style="list-style-type: none"> <li>└ EP1 Bulk (out) 64 bytes</li> <li>└ EP2 Bulk (in) 64 bytes</li> <li>└ EP3 Interrupt (in) 16 bytes</li> <li>└ EP4 Bulk (out) 64 bytes</li> <li>└ EP5 Bulk (in) 64 bytes</li> <li>└ EP6 Interrupt (in) 16 bytes</li> <li>└ EP7 Bulk (out) 64 bytes</li> <li>└ EP8 Bulk (in) 64 bytes</li> <li>└ EP9 Interrupt (in) 16 bytes</li> </ul> </li> </ul> </li> </ul> |

## (2) State Transition

Figure 27.10 shows the state transition after this LSI is started in USB boot mode.

**Figure 27.10 USB Boot Mode**

1. When a transition to USB boot mode is made, the boot program embedded in this LSI is initiated. When the USB boot program is initiated, this LSI performs enumeration with the host. When enumeration is completed, the host transmits 1 byte of H'55 to this LSI. When the LSI cannot receive the byte normally, USB boot mode should be initiated again.
2. An inquiry about the size, configuration, start address, and support status of the user MAT and user boot MAT is transmitted to the host.
3. After inquiries have finished, all user MAT/user boot MAT are automatically erased.

4. After the user MAT/user boot MAT is erased automatically, the LSI waits for a programming/erasing command. After receiving a programming command, the LSI waits for programming data. The same applies to erasure.

In addition to the programming/erasing command, there are the sum check command and blank check (erasure check) command of the user MAT/user boot MAT, and memory read command, and current status information acquisition command.

### (3) Notes when Executing USB Boot Mode

- The USB module needs a 48-MHz clock. Set the frequency of the external clock and the clock oscillator to implement a 48-MHz USB-dedicated clock (U $\phi$ ). For details, see section 4, Clock Pulse Generator (CPG).
- The PB14 pin is used to select the clock supplied to the USB.  
PB14 = 0: USBEXTAL or USBXTAL is used.  
PB14 = 1: The system clock is used.
- When PB14 = 0, connect a 48-MHz oscillator to USBEXTAL or USBXTAL.
- When PB14 = 1, connect a 12-MHz oscillator to EXTAL or XTAL with USBEXTAL = 0 and USBXTAL = open.
- For the D+ pull-up control connection, use the PUPD pin (PB15).
- To maintain stable power supply when programming or erasing flash memory, the cable should not be connected via the bus-powered hub.
- Note especially that unplugging the USB cable while the flash memory is being programmed or erased may destroy the LSI permanently in the worst case.

## 27.5.5 Inquiry/Selection Host Command Wait State

Table 27.7 shows the host commands available in inquiry/selection host command wait state. The boot program status inquiry command can also be used in programming/erasure host command wait state. The other commands can only be used in inquiry/selection host command wait state.

**Table 27.7 Inquiry/Selection Host Commands**

| Host Command Name                                    | Function                                                                                                                                             |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Supported device inquiry                             | Inquires regarding the device codes and the product codes for the embedded programs                                                                  |
| Device selection                                     | Selects a device code                                                                                                                                |
| Clock mode inquiry                                   | Inquires regarding the clock mode                                                                                                                    |
| Clock mode selection                                 | Selects a clock mode                                                                                                                                 |
| Multiplication ratio inquiry                         | Inquires regarding the number of clock types, the number of multiplication/division ratios, and the multiplication/division ratios                   |
| Operating frequency inquiry                          | Inquires regarding the number of clock types and the maximum and minimum operating frequencies                                                       |
| User boot MAT information inquiry                    | Inquires regarding the number of user boot MATs and the start and end addresses                                                                      |
| User MAT information inquiry                         | Inquires regarding the number of user MATs and the start and end addresses                                                                           |
| Erase block information inquiry                      | Inquires regarding the number of blocks and the start and end addresses                                                                              |
| Programming size inquiry                             | Inquires regarding the size of programming data                                                                                                      |
| Simultaneous two-MAT programming information inquiry | Inquires regarding the availability of simultaneous two-MAT programming function                                                                     |
| New bit rate selection                               | Modifies the bit rate of SCI communications between the host and this LSI                                                                            |
| Programming/erasure state transition                 | Erases the entire area of each of the user MAT, user boot MAT, and FLD data MAT and makes this LSI enter programming/erasure host command wait state |
| Boot program status inquiry                          | Inquires regarding the state of this LSI                                                                                                             |

If the host has sent an undefined command, this LSI returns a response indicating a command error in the format shown below. The command field holds the first byte of the undefined command sent from the host.

|                |      |         |
|----------------|------|---------|
| Error response | H'80 | Command |
|----------------|------|---------|

In inquiry/selection host command wait state, send selection commands from the host in the order of device selection, clock mode selection, and new bit rate selection to set up this LSI according to the responses to inquiry commands. Note that the supported device inquiry and clock mode inquiry commands are the only inquiry commands that can be sent before the clock mode selection command; other inquiry commands must not be issued before the clock mode selection command. If commands are issued in an incorrect order, this LSI returns a response indicating a command error. Figure 27.11 shows an example of the procedure to use inquiry/selection host commands.

**Figure 27.11 Example of Procedure to Use Inquiry/Selection Host Commands**

Each host command is described in detail below. The "command" in the description indicates a command sent from the host to this LSI and the "response" indicates a response sent from this LSI to the host. The "checksum" is byte-size data calculated so that the sum of all bytes to be sent by this LSI becomes H'00.

## (1) Supported Device Inquiry

In response to a supported device inquiry command sent from the host, this LSI returns the information concerning the devices supported by the embedded program for boot mode. If the supported device inquiry command comes after the host has selected a device, this LSI only returns the information concerning the selected device.

|          |                 |             |              |
|----------|-----------------|-------------|--------------|
| Command  | H'20            |             |              |
| Response | H'30            | Size        | Device count |
|          | Character count | Device code |              |
|          | Character count | Device code |              |
|          | :               | :           | :            |
|          | Character count | Device code |              |
|          | SUM             |             |              |
|          | Product code    |             |              |

### [Legend]

Size (1 byte): Total number of bytes in the device count, character count, device code, and product code fields

Device count (1 byte): Number of device types supported by the embedded program for boot mode

Character count (1 byte): Number of characters included in the device code and product code fields

Device code (4 bytes): ASCII code for the product name of the chip

Product code (n bytes): ASCII code for the supported device

SUM (1 byte): Checksum

## (2) Device Selection

In response to a device selection command sent from the command, this LSI checks if the selected device is supported. When the selected device is supported, this LSI specifies this device as the device for use and returns a response (H'06). If the selected device is not supported or the sent command is illegal, this LSI returns an error response (H'90).

Even when H'01 has been returned as the number of supported devices in response to a supported device inquiry command, issue a device selection command to specify the device code that has been returned as the result of the inquiry.

|                |      |       |             |     |
|----------------|------|-------|-------------|-----|
| Command        | H'10 | Size  | Device code | SUM |
| Response       | H'06 |       |             |     |
| Error response | H'90 | Error |             |     |

### [Legend]

Size (1 byte): Number of characters in the device code field (fixed at four)

Device code (4 bytes): ASCII code for the product name of the chip (one of the device codes returned in response to the supported device inquiry command)

SUM (1 byte): Checksum

Error (1 byte): Error code

H'11: Checksum error (illegal command)

H'21: Incorrect device code error

### (3) Clock Mode Inquiry

In response to a clock mode inquiry command sent from the host, this LSI returns the supported clock modes. If the clock mode inquiry command comes after the host has selected a clock mode, this LSI only returns the information concerning the selected clock mode.

|          |      |      |     |      |
|----------|------|------|-----|------|
| Command  | H'21 |      |     |      |
| Response | H'31 | Size |     |      |
|          | Mode | Mode | ... | Mode |
|          | SUM  |      |     |      |

#### [Legend]

- Size (1 byte): Total number of bytes in the mode count and mode fields
- Mode (1 byte): Supported clock mode (for example, H'01 indicates clock mode 1)
- SUM (1 byte): Checksum

#### (4) Clock Mode Selection

In response to a clock mode selection command sent from the host, this LSI checks if the selected clock mode is supported. When the selected mode is supported, this LSI specifies this clock mode for use and returns a response (H'06). If the selected mode is not supported or the sent command is illegal, this LSI returns an error response (H'91).

Be sure to issue a clock mode selection command only after issuing a device selection command. Even when H'00 or H'01 has been returned as the number of supported clock modes in response to a clock mode inquiry command, issue a clock mode selection command to specify the clock mode that has been returned as the result of the inquiry.

|         |      |      |      |     |
|---------|------|------|------|-----|
| Command | H'11 | Size | Mode | SUM |
|---------|------|------|------|-----|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

|                |      |       |
|----------------|------|-------|
| Error response | H'91 | Error |
|----------------|------|-------|

##### [Legend]

Size (1 byte): Number of characters in the mode field (fixed at 1)

Mode (1 byte): Clock mode (one of the clock modes returned in response to the clock mode inquiry command)

SUM (1 byte): Checksum

Error (1 byte): Error code

H'11: Checksum error (illegal command)

H'22: Incorrect clock mode error

## (5) Multiplication Ratio Inquiry

In response to a multiplication ratio inquiry command sent from the host, this LSI returns the clock types, the number of multiplication/division ratios, and the multiplication division ratios supported.

Command

|      |
|------|
| H'22 |
|------|

Response

| H'32                       | Size                 | Clock type count     |     |                      |
|----------------------------|----------------------|----------------------|-----|----------------------|
| Multiplication ratio count | Multiplication ratio | Multiplication ratio | ... | Multiplication ratio |
| Multiplication ratio count | Multiplication ratio | Multiplication ratio | ... | Multiplication ratio |
| :                          | :                    | :                    | ... | :                    |
| Multiplication ratio count | Multiplication ratio | Multiplication ratio | ... | Multiplication ratio |
| SUM                        |                      |                      |     |                      |

[Legend]

Size (1 byte): Total number of bytes in the clock type count, multiplication ratio count, and multiplication ratio fields

Clock type count (1 byte): Number of clock types (for example, H'02 indicates two clock types; that is, an internal clock and a peripheral clock)

Multiplication ratio count (1 byte): Number of supported multiplication/division ratios (for example, H'03 indicates that three multiplication ratios are supported for the internal clock (x4, x6, and x8))

Multiplication ratio (1 byte): A positive value indicates a multiplication ratio (for example, H'04 = 4 = multiplication by 4)  
A negative value indicates a division ratio (for example, H'FE = -2 = division by 2)

SUM (1 byte): Checksum

## (6) Operating Clock Frequency Inquiry

In response to an operating clock frequency inquiry command sent from the host, this LSI returns the minimum and maximum frequencies for each clock.

Command

|      |
|------|
| H'23 |
|------|

Response

| H'33              | Size              | Clock type count |
|-------------------|-------------------|------------------|
| Minimum frequency | Maximum frequency |                  |
| Minimum frequency | Maximum frequency |                  |
| :                 | :                 |                  |
| Minimum frequency | Maximum frequency |                  |
| SUM               |                   |                  |

[Legend]

Size (1 byte): Total number of bytes in the clock type count, minimum frequency, and maximum frequency fields

Clock type count (1 byte): Number of clock types (for example, H'02 indicates two clock types; that is, an internal clock and a peripheral clock)

Minimum frequency (2 bytes): Minimum value of the operating frequency (for example, H'07D0 indicates 20.00 MHz).

This value should be calculated by multiplying the frequency value (MHz) to two decimal places by 100.

Maximum frequency (2 bytes): Maximum value of the operating frequency represented in the same format as the minimum frequency

SUM (1 byte): Checksum

(7) User Boot MAT Information Inquiry

In response to a user boot MAT information inquiry command sent from the host, this LSI returns the number of user boot MATs and their addresses.

|          |                   |      |           |
|----------|-------------------|------|-----------|
| Command  | H'24              |      |           |
| Response | H'34              | Size | MAT count |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | :                 |      |           |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | SUM               |      |           |

[Legend]

- Size (1 byte):Total number of bytes in the MAT count, MAT start address, and MAT end address fields
- MAT count (1 byte):Number of user boot MATs (consecutive areas are counted as one MAT)
- MAT start address (4 bytes):Start address of a user boot MAT
- MAT end address (4 bytes):End address of a user boot MAT
- SUM (1 byte):Checksum

(8) User MAT Information Inquiry

In response to a user MAT information inquiry command sent from the host, this LSI returns the number of user MATs and their addresses.

|          |                   |      |           |
|----------|-------------------|------|-----------|
| Command  | H'25              |      |           |
| Response | H'35              | Size | MAT count |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | :                 |      |           |
|          | MAT start address |      |           |
|          | MAT end address   |      |           |
|          | SUM               |      |           |

[Legend]

- Size (1 byte):Total number of bytes in the MAT count, MAT start address, and MAT end address fields
- MAT count (1 byte):Number of user MATs (consecutive areas are counted as one MAT)
- MAT start address (4 bytes):Start address of a user MAT
- MAT end address (4 bytes):End address of a user MAT
- SUM (1 byte):Checksum

## (9) Erasure Block Information Inquiry

In response to an erasure block information inquiry command sent from the host, this LSI returns the number of erasure blocks in the user MAT and their addresses.

Command

|      |
|------|
| H'26 |
|------|

Response

| H'36                | Size | Block count |
|---------------------|------|-------------|
| Block start address |      |             |
| Block end address   |      |             |
| Block start address |      |             |
| Block end address   |      |             |
| :                   |      |             |
| Block start address |      |             |
| Block end address   |      |             |
| SUM                 |      |             |

[Legend]

Size (2 bytes): Total number of bytes in the block count, block start address, and block end address fields

Block count (1 byte): Number of erasure blocks in the user MAT

Block start address (4 bytes): Start address of an erasure block

Block end address (4 bytes): End address of an erasure block

SUM (1 byte): Checksum

## (10) Programming Size Inquiry

In response to a programming size inquiry command sent from the host, this LSI returns the programming size.

Command

|      |
|------|
| H'27 |
|------|

Response

|      |      |                  |     |
|------|------|------------------|-----|
| H'37 | Size | Programming size | SUM |
|------|------|------------------|-----|

### [Legend]

Size (1 byte):      Number of characters included in the programming size field (fixed at two)

Programming size (2 bytes):      Programming unit (bytes)

SUM (1 byte):      Checksum

## (11) New Bit Rate Selection

In response to a new bit rate selection command sent from the host, this LSI checks if the on-chip SCI can be set to the selected new bit rate. When the SCI can be set to the new bit rate, this LSI returns a response (H'06) and sets the SCI to the new bit rate. If the SCI cannot be set to the new bit rate or the sent command is illegal, this LSI returns an error response (H'BF). Upon reception of response H'06, the host waits for a one-bit period in the previous bit rate with which the new bit rate selection command has been sent, and then sets the host bit rate to the new one. After that, the host sends confirmation data (H'06) in the new bit rate, and this LSI returns a response (H'06) to the confirmation data.

Be sure to issue a new bit rate selection command only after a clock mode selection command.

**Figure 27.12 New Bit Rate Selection Sequence**

|                |                  |                        |                        |                 |
|----------------|------------------|------------------------|------------------------|-----------------|
| Command        | H'3F             | Size                   | Bit rate               | Input frequency |
|                | Clock type count | Multiplication ratio 1 | Multiplication ratio 2 |                 |
|                | SUM              |                        |                        |                 |
| Response       | H'06             |                        |                        |                 |
| Error response | H'BF             | Error                  |                        |                 |
| Confirmation   | H'06             |                        |                        |                 |
| Response       | H'06             |                        |                        |                 |

## [Legend]

Size (1 byte): Total number of bytes in the bit rate, input frequency, clock type count, and multiplication ratio fields

Bit rate (2 bytes): New bit rate (for example, H'00C0 indicates 19200 bps)  
1/100 of the new bit rate value should be specified.

Input frequency (2 bytes): Clock frequency input to this LSI (for example, H'07D0 indicates 20.00 MHz)  
This value should be calculated by multiplying the input frequency value to two decimal places by 100.

Clock type count (1 byte): Number of clock types (for example, H'02 indicates two clock types; that is, an internal clock and a peripheral clock)

Multiplication ratio 1 (1 byte): Multiplication/division ratio of the input frequency to obtain the internal clock  
A positive value indicates a multiplication ratio (for example, H'04 = 4 = multiplication by 4)  
A negative value indicates a division ratio (for example, HFE = -2 = division by 2)

Multiplication 2 (1 byte): Multiplication/division ratio of the input frequency to obtain the peripheral clock  
This value is represented in the same format as multiplication ratio 1

SUM (1 byte): Checksum

Error: Error code

H'11: Checksum error

H'24: Bit rate selection error

H'25: Input frequency error

H'26: Multiplication ratio error

H'27: Operating frequency error

- Bit rate selection error

A bit rate selection error occurs when the bit rate selected through a new bit rate selection command cannot be set for the SCI of this LSI within an error of 4%. The bit rate error can be obtained by the following equation from the bit rate (B) selected through a new bit rate selection command, the input frequency (f<sub>EX</sub>), multiplication ratio 2 (Pφ), the SCBRR setting (N) in SCI, and the CKS[1:0] bit value (N) in SCSMR.

$$\text{Error (\%)} = \frac{f_{EX} \times P\phi \times 10^6}{(N+1) \times B \times 64 \times 2^{2n-1}} - 1$$

- Input frequency error

An input frequency error occurs when the input frequency specified through a new bit rate selection command is outside the range from the minimum to maximum input frequencies for the clock mode selected through a clock mode selection command.

- Multiplication ratio error

A multiplication ratio error occurs when the multiplication ratio specified through a new bit rate selection command does not match the clock mode selected through a clock mode selection command. To check the selectable multiplication ratios, issue a multiplication ratio inquiry command.

- Operating frequency error

An operating frequency error occurs when this LSI cannot operate at the operating frequencies selected through a new bit rate selection command. This LSI calculates the operating frequencies from the input frequency and multiplication ratios specified through a new bit rate selection command and checks if each calculated frequency is within the range from the minimum to maximum frequencies for the respective clock. To check the minimum and maximum operating frequencies for each clock, issue an operating clock frequency inquiry command.

## (12) Programming/Erase State Transition

In response to a programming/erase state transition command sent from the host, this LSI erases the entire area of each of the user MAT, user boot MAT, and FLD data MAT. After completing erasure, this LSI returns a response (H'06) and waits for a programming/erase host command. If this LSI has failed to complete erasure due to an error, it returns an error response (sends H'C0 and H'51 in that order).

Do not issue a programming/erase state transition command before device selection, clock mode selection, and new bit rate selection commands.

|                |      |      |
|----------------|------|------|
| Command        | H'40 |      |
| Response       | H'06 |      |
| Error response | H'C0 | H'51 |

## (13) Boot Program Status Inquiry

In response to a boot program status inquiry command sent from the host, this LSI returns its current status. The boot program status inquiry command can be issued in both inquiry/selection host command wait state and programming/erase host command wait state.

|          |      |      |        |       |
|----------|------|------|--------|-------|
| Command  | H'4F |      |        |       |
| Response | H'5F | Size | Status | Error |

### [Legend]

|                  |                                                                     |
|------------------|---------------------------------------------------------------------|
| Size (1 byte):   | Total number of bytes in the status and error fields (fixed at two) |
| Status (1 byte): | Current status in this LSI (see table 27.8)                         |
| Error (1 byte):  | Error status in this LSI (see table 27.9)                           |

**Table 27.8 Status Code**

| <b>Code</b> | <b>Description</b>                                                                                 |
|-------------|----------------------------------------------------------------------------------------------------|
| H'11        | Waiting for device selection                                                                       |
| H'12        | Waiting for clock mode selection                                                                   |
| H'13        | Waiting for bit rate selection                                                                     |
| H'1F        | Waiting for transition to programming/erasure host command wait state (bit rate has been selected) |
| H'31        | Erasing the user MAT and user boot MAT                                                             |
| H'3F        | Waiting for a programming/erasure host command                                                     |
| H'4F        | Waiting for reception of programming data                                                          |
| H'5F        | Waiting for erasure block selection                                                                |

**Table 27.9 Error Code**

| <b>Code</b> | <b>Description</b>                     |
|-------------|----------------------------------------|
| H'00        | No error                               |
| H'11        | Checksum error                         |
| H'21        | Incorrect device code error            |
| H'22        | Incorrect clock mode error             |
| H'24        | Bit rate selection error               |
| H'25        | Input frequency error                  |
| H'26        | Multiplication ratio error             |
| H'27        | Operating frequency error              |
| H'29        | Block number error                     |
| H'2A        | Address error                          |
| H'2B        | Data size error                        |
| H'51        | Erasure error                          |
| H'52        | Incomplete erasure error               |
| H'53        | Programming error                      |
| H'54        | Selection error                        |
| H'80        | Command error                          |
| H'FF        | Bit rate adjustment verification error |

### 27.5.6 Programming/Erasing Host Command Wait State

Table 27.10 shows the host commands available in programming/erasure host command wait state.

**Table 27.10 Programming/Erasure Host Commands**

| Host Command Name                               | Function                                                      |
|-------------------------------------------------|---------------------------------------------------------------|
| User boot MAT programming selection             | Selects the program for user boot MAT programming             |
| User MAT programming selection                  | Selects the program for user MAT programming                  |
| Simultaneous two-user MAT programming selection | Selects the program for simultaneous two-user MAT programming |
| 256-byte programming                            | Programs 256 bytes of data                                    |
| Erasure selection                               | Selects the erasure program                                   |
| Block erasure                                   | Erases block data                                             |
| Memory read                                     | Reads data from memory                                        |
| User boot MAT checksum                          | Performs checksum verification for the user boot MAT          |
| User MAT checksum                               | Performs checksum verification for the user MAT               |
| User boot MAT blank check                       | Checks whether the user boot MAT is blank                     |
| User MAT blank check                            | Checks whether the user MAT is blank                          |
| Read lock bit status                            | Reads from the lock bit                                       |
| Lock bit program                                | Writes to the lock bit                                        |
| Lock bit enabled                                | Enables the lock bit protect                                  |
| Lock bit disable                                | Disables the lock bit protect                                 |
| Boot program status inquiry                     | Inquires regarding the state of this LSI                      |

If the host has sent an undefined command, this LSI returns a response indicating a command error. For the format of this response, see section 27.5.5, Inquiry/Selection Host Command Wait State.

To program the ROM, issue a programming selection command (user boot MAT programming selection or user MAT programming selection command) and then a 256-byte programming command from the host. Upon reception of a programming selection command, this LSI enters programming data wait state (see section 27.5.2, State Transition in Boot Mode). In response to a 256-byte programming command sent from the host in this state, this LSI starts programming the ROM. When the host sends a 256-byte programming command specifying H'FFFFFFFF as the

programming start address, this LSI detects it as the end of programming and enters programming/erasure host command wait state.

To erase the ROM, issue an erasure selection command and then a block erasure command from the host. Upon reception of an erasure selection command, this LSI enters erasure block selection wait state (see section 27.5.2, State Transition in Boot Mode). In response to a block erasure command sent from the host in this state, this LSI erases the specified block in the ROM. When the host sends a block erasure command specifying H'FF as the block number, this LSI detects it as the end of erasure and enters programming/erasure host command wait state.

**Figure 27.13 Procedure for ROM Programming in Boot Mode**

**Figure 27.14 Procedure for ROM Erasure in Boot Mode**

Each host command is described in detail below. The "command" in the description indicates a command sent from the host to this LSI and the "response" indicates a response sent from this LSI to the host. The "checksum" is byte-size data calculated so that the sum of all bytes to be sent by this LSI becomes H'00.

### (1) User Boot MAT Programming Selection

In response to a user boot MAT programming selection command sent from the host, this LSI selects the program for user boot MAT programming and waits for programming data.

|         |      |
|---------|------|
| Command | H'42 |
|---------|------|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

### (2) User MAT Programming Selection

In response to a user MAT programming selection command sent from the host, this LSI selects the program for user MAT programming and waits for programming data.

|         |      |
|---------|------|
| Command | H'43 |
|---------|------|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

### (3) 256-Byte Programming

In response to a 256-byte programming command sent from the host, this LSI programs the ROM. After completing ROM programming successfully, this LSI returns a response (H'06). If an error has occurred during ROM programming, this LSI returns an error response (H'D0).

|         |      |                     |     |      |  |
|---------|------|---------------------|-----|------|--|
| Command | H'50 | Programming Address |     |      |  |
|         | Data | Data                | ... | Data |  |
|         | SUM  |                     |     |      |  |

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

|                |      |       |
|----------------|------|-------|
| Error response | H'D0 | Error |
|----------------|------|-------|

#### [Legend]

Programming address (4 bytes): Target address of programming  
 To program the ROM, a 256-byte boundary address should be specified.

To terminate programming, H'FFFFFFFF should be specified.

Data (256 bytes): Programming data  
 H'FF should be specified for the bytes that do not need to be programmed.  
 When terminating programming, no data needs to be specified (only the programming address and SUM should be sent in that order).

SUM (1 byte): Checksum

Error (1 byte): Error code

H'11: Checksum error

H'2A: Address error (the specified address is not in the target MAT)

H'53: Programming cannot be done due to a programming error

#### (4) Erasure Selection

In response to an erasure selection command sent from the host, this LSI selects the erasure program and waits for erasure block specification.

|         |      |
|---------|------|
| Command | H'48 |
|---------|------|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

#### (5) Block Erasure

In response to a block erasure command sent from the host, this LSI erases the ROM. After completing ROM erasure successfully, this LSI returns a response (H'06). If an error has occurred during ROM erasure, this LSI returns an error response (H'D8).

|         |      |      |       |     |
|---------|------|------|-------|-----|
| Command | H'58 | Size | Block | SUM |
|---------|------|------|-------|-----|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

|                |      |       |
|----------------|------|-------|
| Error response | H'D8 | Error |
|----------------|------|-------|

#### [Legend]

Size (1 byte): Number of bytes in the block specification field (fixed at 1)

Block (1 byte): Block number whose data is to be erased  
To terminate erasure, H'FF should be specified.

SUM (1 byte): Checksum

Error (1 byte): Error code

H'11: Checksum error

H'29: Block number error (an incorrect block number is specified)

H'51: Erasure cannot be done due to an erasure error

## (6) Memory Read

In response to a memory read command sent from the host, this LSI reads data from the ROM. After completing ROM reading, this LSI returns the data stored in the address specified by the memory read command. If this LSI has failed to read the ROM, this LSI returns an error response (H'D2).

|                |              |              |      |                    |  |
|----------------|--------------|--------------|------|--------------------|--|
| Command        | H'52         | Size         | Area | Read start address |  |
|                | Reading size |              |      | SUM                |  |
| Response       | H'52         | Reading size |      |                    |  |
|                | Data         | Data         | ...  | Data               |  |
|                | SUM          |              |      |                    |  |
| Error response | H'D2         | Error        |      |                    |  |

### [Legend]

Size (1 byte): Total number of bytes in the area, read start address, and reading size fields

Area (1 byte): Target MAT to be read

H'00: User boot MAT

H'01: User MAT

Read start address (4 bytes): Start address of the area to be read

Reading size (4 bytes): Size of data to be read (bytes)

SUM (1 byte): Checksum

Data (1 byte): Data read from the ROM

Error (1 byte): Error code

H'11: Checksum error

H'2A: Address error

- The value specified for area selection is neither H'00 nor H'01.

- The specified read start address is outside the selected MAT.

H'2B: Data size error

- H'00 is specified for the reading size.

- The reading size is larger than the MAT.

- The end address calculated from the read start address and the reading size is outside the selected MAT.

## (7) User Boot MAT Checksum

In response to a user boot MAT checksum command sent from the host, this LSI sums the user boot MAT data in byte units and returns the result (checksum).

Command 

|      |
|------|
| H'4A |
|------|

Response 

|      |      |              |     |
|------|------|--------------|-----|
| H'5A | Size | MAT checksum | SUM |
|------|------|--------------|-----|

[Legend]

Size (1 byte):      Number of bytes in the MAT checksum field (fixed at 4)

MAT checksum (4 bytes):      Checksum of the user boot MAT data

SUM (1 byte):      Checksum (for the response data)

## (8) User MAT Checksum

In response to a user MAT checksum command sent from the host, this LSI sums the user MAT data in byte units and returns the result (checksum).

Command 

|      |
|------|
| H'4B |
|------|

Response 

|      |      |              |     |
|------|------|--------------|-----|
| H'5B | Size | MAT checksum | SUM |
|------|------|--------------|-----|

[Legend]

Size (1 byte):      Number of bytes in the MAT checksum field (fixed at 4)

MAT checksum (4 bytes):      Checksum of the user MAT data

The user MAT also stores the key code for debugging function authentication. Note that the checksum includes this key code value.

SUM (1 byte):      Checksum (for the response data)

### (9) User Boot MAT Blank Check

In response to a user boot MAT blank check command sent from the host, this LSI checks whether the user boot MAT is completely erased. When the user boot MAT is completely erased, this LSI returns a response (H'06). If the user boot MAT has an unerased area, this LSI returns an error response (sends H'CC and H'52 in that order).

|                |      |      |
|----------------|------|------|
| Command        | H'4C |      |
| Response       | H'06 |      |
| Error response | H'CC | H'52 |

### (10) User MAT Blank Check

In response to a user MAT blank check command sent from the host, this LSI checks whether the user MAT is completely erased. When the user MAT is completely erased, this LSI returns a response (H'06). If the user MAT has an unerased area, this LSI returns an error response (sends H'CD and H'52 in that order).

|                |      |      |
|----------------|------|------|
| Command        | H'4D |      |
| Response       | H'06 |      |
| Error response | H'CD | H'52 |

## (11) Read Lock Bit Status

In response to a read lock bit status command sent from the host, this LSI reads data from the lock bit. After completing the lock bit reading, this LSI returns the data stored in the address specified by the read lock bit status command. If this LSI has failed to read the lock bit, this LSI returns an error response (H'F1).

|         |      |      |      |                |               |     |
|---------|------|------|------|----------------|---------------|-----|
| Command | H'71 | Size | Area | Medium address | Upper address | SUM |
|---------|------|------|------|----------------|---------------|-----|

|          |        |
|----------|--------|
| Response | Status |
|----------|--------|

|                |      |       |
|----------------|------|-------|
| Error response | H'F1 | Error |
|----------------|------|-------|

### [Legend]

Size (1 byte): Total number of bytes in the area, medium address, and upper address (fixed at 3 in this LSI)

Area (1 byte): Target MAT to be read

H'00: User boot MAT

H'01: User MAT

Medium address (1 byte): Medium address at the end of the specified address (8 to 15 bits)

Upper address (1 byte): Upper address at the end of the specified address (16 to 23 bits)

SUM (1 byte): Checksum

Status (1 byte): Bit 6 locked at "0"

Bit 6 unlocked at "1"

Error (1 byte): Error code

H'11: Checksum error

H'2A: Address error (the specified address is not in the target MAT)

## (12) Lock Bit Program

In response to a lock bit program command sent from the host, this LSI writes to a lock bit and locks the specified block. After completing the lock bit blocking, this LSI returns a response (H'06). If this LSI has failed to lock, this LSI returns an error response (H'F7).

|         |      |      |      |                |               |     |
|---------|------|------|------|----------------|---------------|-----|
| Command | H'77 | Size | Area | Medium address | Upper address | SUM |
|---------|------|------|------|----------------|---------------|-----|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

|                |      |       |
|----------------|------|-------|
| Error response | H'F7 | Error |
|----------------|------|-------|

### [Legend]

Size (1 byte): Total number of bytes in the area, medium address, and upper address (fixed at 3 in this LSI)

Area (1 byte): Target MAT to be locked

H'00: User boot MAT

H'01: User MAT

Medium address (1 byte): Medium address at the end of the specified address (8 to 15 bits)

Upper address (1 byte): Upper address at the end of the specified address (16 to 23 bits)

SUM (1 byte): Checksum

Error (1 byte): Error code

H'11: Checksum error

H'2A: Address error (the specified address is not in the target MAT)

H'53: Locking cannot be done due to a programming error

**(13) Lock Bit Enable**

In response to a lock bit enable command sent from the host, this LSI enables a lock bit.

|         |      |
|---------|------|
| Command | H'7A |
|---------|------|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

**(14) Lock Bit Disable**

In response to a lock bit enable command sent from the host, this LSI disables a lock bit.

|         |      |
|---------|------|
| Command | H'75 |
|---------|------|

|          |      |
|----------|------|
| Response | H'06 |
|----------|------|

**(15) Boot Program Status Inquiry**

For details, refer to section 27.5.5, Inquiry/Selection Host Command Wait State.

## 27.6 User Program Mode

### 27.6.1 FCU Command List

To program or erase the user MAT in user program mode, issue FCU commands to the FCU. Table 27.11 is a list of FCU commands for ROM programming and erasure.

**Table 27.11 FCU Command List (ROM-Related Commands)**

| Command                                         | Function                                                                                                           |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Normal mode transition                          | Moves to the normal mode (see section 27.6.2, Conditions for FCU Command Acceptance)                               |
| Status read mode transition                     | Moves to the status read mode (see section 27.6.2, Conditions for FCU Command Acceptance)                          |
| Lock bit read mode transition (lock bit read 1) | Moves to the lock bit read mode (see section 27.6.2, Conditions for FCU Command Acceptance)                        |
| Program                                         | Programs ROM (in 256-byte units)                                                                                   |
| Block erase                                     | Erases ROM (in block units; erasing the lock bit)                                                                  |
| P/E suspend                                     | Suspends programming or erasure                                                                                    |
| P/E resume                                      | Resumes programming or erasure                                                                                     |
| Status register clear                           | Clears the ILGLERR, ERSERR, and PRGERR bits in FSTATR0 and cancels the command-locked state                        |
| Lock bit read 2                                 | Reads the lock bit of a specified erasure block (updates the FLOCKST bit in FSTATR1 to reflect the lock bit state) |
| Lock bit program                                | Writes to the lock bit of a specified erasure block                                                                |
| Peripheral clock notification                   | Specifies the peripheral clock frequency                                                                           |

FCU commands other than the lock bit read 2 program and lock bit program are also used for FLD programming and erasure. When a lock bit read 2 command is issued to the FLD, an FLD blank check is executed. When a lock bit program command is issued to the FLD, it is detected as an illegal command and generates an error (see section 28, Data Flash (FLD)).

To issue a command to the FCU, write to a ROM program/erase address through the P bus. Table 27.12 shows the FCU command format. Performing P-bus write access as shown in table 27.12 under specified conditions starts each command processing in the FCU. For the conditions for FCU command acceptance, refer to section 27.6.2, Conditions for FCU Command Acceptance. For details of each FCU command, refer to section 27.6.3, FCU Command Usage.

When H'71 is sent in the first cycle of an FCU command while the FRDMD bit is 0 (memory area read mode), the FCU accepts the lock bit read mode transition command (lock bit read 1). When a ROM program/erase address is read through the P bus after transition to the lock bit read mode, the FCU copies the lock bit of the erasure block corresponding to the accessed address into all bits in the read data. When H'71 is sent in the first cycle of the FCU command while the FRDMD bit is 1 (register read mode), the FCU waits for the second-cycle data (H'D0) of the lock bit read 2 command. When a ROM program/erase address is written to through the P bus in this state, the FCU copies the lock bit of the erasure block corresponding to the accessed address into the FLOCKST bit in FSTATR1.

There are two suspending modes to be initiated by the P/E suspend command; the suspension-priority mode and erasure-priority mode. For details of each mode, refer to section 27.6.4, Suspending Operation.

**Table 27.12 FCU Command Format**

| Command                                            | Number of Bus Cycles | First Cycle |      | Second Cycle |      | Third Cycle |        | Fourth and Fifth Cycles |        | Sixth Cycle |      | Seventh to 130th Cycles |      | 131st Cycle |      |
|----------------------------------------------------|----------------------|-------------|------|--------------|------|-------------|--------|-------------------------|--------|-------------|------|-------------------------|------|-------------|------|
|                                                    |                      | Address     | Data | Address      | Data | Address     | Data   | Address                 | Data   | Address     | Data | Address                 | Data | Address     | Data |
| Normal mode transition                             | 1                    | RA          | H'FF | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Status read mode transition                        | 1                    | RA          | H'70 | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Lock bit read mode transition<br>(lock bit read 1) | 1                    | RA          | H'71 | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Program                                            | 131                  | RA          | H'E8 | RA           | H'80 | WA          | WD1    | RA                      | WDn    | RA          | WDn  | RA                      | WDn  | RA          | H'D0 |
| Block erase                                        | 2                    | RA          | H'20 | BA           | H'D0 | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| P/E suspend                                        | 1                    | RA          | H'B0 | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| P/E resume                                         | 1                    | RA          | H'D0 | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Status register clear                              | 1                    | RA          | H'50 | —            | —    | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Lock bit read 2                                    | 2                    | RA          | H'71 | BA           | H'D0 | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Lock bit program                                   | 2                    | RA          | H'77 | BA           | H'D0 | —           | —      | —                       | —      | —           | —    | —                       | —    | —           | —    |
| Peripheral clock notification                      | 6                    | RA          | H'E9 | RA           | H'03 | WA          | H'0F0F | WA                      | H'0F0F | RA          | H'D0 | —                       | —    | —           | —    |

**[Legend]**

- RA: ROM program/erase address  
An address in the range from H'80800000 to H'808FFFFFF
- WA: ROM program address  
Start address of 256-byte programming data
- BA: ROM erasure block address  
An address in the target erasure block (specified by the ROM program/erase address)
- WDn: n-th word of programming data (n = 1 to 128)

## 27.6.2 Conditions for FCU Command Acceptance

The FCU determines whether to accept a command depending on the FCU mode or status. Figure 27.15 is an FCU mode transition diagram.

**Figure 27.15 FCU Mode Transition Diagram (ROM-Related Modes)**

## (1) ROM Read Mode

- ROM/FLD read mode

The ROM and FLD can be read through the ROM cache and HPB, respectively, at a high speed. The FCU does not accept commands. The FCU enters this mode when the FENTRY0 bit in FENTRYR is set to 0 and the FENTRYD bit to 0 in FENTRYR.

- FLD P/E mode

The ROM can be read through the ROM cache at a high speed. The FCU accepts commands for FLD, but does not accept commands for ROM. The FCU enters this mode when the FENTRY0 bit is set to 0 and the FENTRYD bit to 1. For details of the FLD P/E mode, refer to section 27.6.2, Conditions for FCU Command Acceptance.

## (2) ROM P/E Mode

- ROM P/E normal mode

The FCU enters this mode when the FENTRYD bit is set to 0 and the FENTRY0 bit is set to 1 in ROM read mode, or when a normal mode transition command is accepted in ROM P/E mode. Table 27.13 shows the commands that can be accepted in this mode. High-speed read operation is not available for the ROM. If an address in the range from H'80800000 to H'808FFFFFF is read through the P-bus while the FENTRY0 bit is set to 1, a ROM access error occurs and the FCU enters the command-locked state (see section 27.9.3, Error Protection).

- ROM status read mode

The FCU enters this mode when the FCU accepts a command that is neither a normal mode transition command nor a lock bit read mode transition command in ROM P/E mode. The ROM status read mode includes the state in which the FRDY bit in FSTATR0 is 0 and the command-locked state after an error has occurred. Table 27.13 shows the commands that can be accepted in this mode. High-speed read operation is not available for the ROM. If an address in the range from H'80800000 to H'808FFFFFF is read through the P-bus while the FENTRY0 bit is set to 1, the FSTATR0 value is read.

- ROM lock bit read mode

The FCU enters this mode when the FCU accepts a lock bit read mode transition command in ROM P/E mode. Table 27.13 shows the commands that can be accepted in this mode. High-speed read operation is not available for the ROM. The FENTRYR value is the same as that in ROM P/E normal mode. If an address in the range from H'80800000 to H'808FFFFFF is read through the P-bus while the FENTRY0 bit is set to 1, the lock bit value of the target erasure block is returned through all bits in the read data.

Table 27.13 shows the acceptable commands in each FCU mode/state. When a command that cannot be accepted is issued, the FCU enters the command-locked state (see section 27.9.3, Error Protection).

To make sure that the FCU accepts a command, enter the mode in which the FCU can accept the target command, check the FRDY, ILGLERR, ERSERR, and PRGERR bit values in FSTATR0, and the FCUERR bit value in FSTATR1, and then issue the target FCU command. The CMDLK bit in FSTAT holds a value obtained by logical ORing the ILGLERR, ERSERR, and PRGERR bit values in FSTATR0 and the FCUERR bit value in the FSTATR1. Therefore the FCU's error occurrence state can be checked by reading the CMDLK bit. In table 27.13, the CMDLK bit is used as the bit to indicate the error occurrence state. The FRDY bit of FSTATR0 is 0 during the programming/erasure, programming/erasure suspension, and lock bit read 2 processes. While the FRDY bit is 0, the P/E suspend command can be accepted only when the SUSRDY bit in FSTATR0 is 1.

Table 27.13 includes 0 and 1 in single cells of the ERSSPD, PRGSPD, and FRDY bit rows for the sake of simplification. The ERSSPD bits 1 and 0 indicate the erasure suspension and programming suspension processes, respectively. The PRGSPD bits 1 and 0 indicate the programming suspension and erasure suspension processes, respectively. The FRDY bit value can be either 1 or 0, which is a value held by the bit prior to a transition to the command lock state.

**Table 27.13 FCU Modes/States and Acceptable Commands**

| Item                                            | P/E Normal Mode       |                   |             | Status Read Mode               |                                           |                            |                       |                   |                | Lock Bit Read Mode |                       |                   |             |

×: Not acceptable

### 27.6.3 FCU Command Usage

This section shows examples of user processing procedures for firmware transfer to the FCU RAM and the issuing of FCU commands. In some procedures given in this section, the FCU state is not checked before an FCU command is issued but the command result is checked before the processing is completed. To make sure that the FCU accepts a command, check the FCU state before starting processing (see section 27.6.2, Conditions for FCU Command Acceptance).

In a flow used in this section, the current state of FCU command handling and error occurrence is checked via the FRDY, ILGLERR, ERSERR, PRGERR, SUSRDY, ERSSPD, and PRGSPD bits in FSTATR0 and the FCUERR bit in FSTATR1. Since both FSTATR0 and FSTATR1 can be read in word access at a time, the FCU state can be checked by making register access only once. If the FCU state is checked via the FRDY bit of FSTATR0 and the CMDLK bit of FSTAT, register access must be made twice. However, the state of error occurrence can be checked via the CMDLK bit only.

The FRDY bit retains 0, if the FRDTC and FRCRCT bits are set to 1 to put the FCU into a command-locked state in the middle of its command handling while the FCUERR bit is 1. Since the FCU in a command-locked state halts its processes, the FRDY bit is never set to 1 from 0. If the FRDY retains 0 for a longer period than programming/erasing time or suspend delay time (see section 33, Electrical Characteristics), abnormal operation such as the FCU process halt may have occurred. In such case, initialize the FCU by a FCU reset. If the FRDY is set to 1 upon completion of the FCU command handling, the FCUERR bit is also 0. Therefore, the state of error occurrence can be checked via the ILGLERR, ERSERR, and PRGERR bits.

Figure 27.16 gives an overview of the flow of processing for programming and erasure.

**Figure 27.16 Overview of the Flow of Processing for Programming and Erasure**

## (1) Transferring Firmware to the FCU RAM

To use FCU commands, the FCU firmware must be stored in the FCU RAM. When this LSI is started, the FCU firmware is not stored in the FCU RAM; copy the firmware stored in the FCU firmware area to the FCU RAM. If the FCUERR bit in FSTATR1 is 1, the firmware stored in the FCU RAM may have been damaged; reset the FCU and copy the FCU firmware again in this case.

Figure 27.17 shows the procedure for firmware transfer to the FCU RAM. Before writing data to the FCU RAM, clear FENTRYR to H'0000 to stop the FCU. Transfer firmware to FCU RAM by the CPU or DMAC. For details on the DMAC settings, refer to section 10, Direct Memory Access Controller (DMAC).

**Figure 27.17 Procedure for Firmware Transfer to FCU RAM**

## (2) Jumping to On-Chip RAM

To prevent the fetching of instructions from the flash memory while it is being programmed or erased, execution must be shifted to an area other than the flash memory (ROM). Copy the required program code to on-chip RAM and then have execution jump to the location of the code in the on-chip RAM.

### (3) Entering ROM P/E Mode

To execute ROM-related FCU commands, set the FENTRY0 bit in FENTRYR appropriately to make the FCU enter ROM P/E mode (see section 27.6.2, Conditions for FCU Command Acceptance). For the conditions for writing to the FENTRY0 bit, refer to section 27.3.10, Flash Protect Register (FPROTR).

After a transition from ROM read mode to ROM P/E mode, the FCU is in ROM P/E normal mode.

**Figure 27.18 Procedure for Transition to ROM P/E Mode**

### (4) Using the Peripheral Clock Notification Command

The frequency of the peripheral clock to be used before programming or erasure of the flash memory (ROM) must be set in the PCKAR. Selectable values are in the range from 20 to 50 MHz. If the setting is not in this range, the FCU detects an error and enters the command-locked state (see section 27.9.3, Error Protection).

The peripheral clock notification command is used after setting the PCKAR register. For a peripheral clock notification command, H'E9 and H'03 are written in byte units in the first and second cycles, respectively, to the address for programming or erasure of the ROM. In the third to fifth cycles of the command, writing is executed in word units. As the first address, use an address that is aligned with a four-byte boundary. After H'0F0F has been written as a word unit three times to the address for programming or erasure of the ROM, when H'D0 is written as a byte unit to the address for programming or erasure of the ROM, the FCU starts processing for setting the frequency of the peripheral clock. Completion of the setting can be confirmed by checking the value of the FRDY bit in the FSTATR0 register.

After release from the reset state, if the peripheral clock settings in use are not changed, execution once makes the setting valid for subsequent FCU commands.

[Legend]

 $t_{PCKA}$ : 120  $\mu$ s for  $P\phi = 25$  MHz, 60  $\mu$ s for  $P\phi = 50$  MHzNote: \*  $t_{RESW2}$  denotes the width of a reset pulse during programming or erasure (see section 33, Electrical Characteristics).**Figure 27.19 Flow for Using the Peripheral Clock Notification Command**

## (5) Entering ROM Read Mode

To enable high-speed ROM read access through the ROM cache, clear the FENTRY0 bit in FENTRYR to make the FCU enter ROM read mode (see section 27.6.2, Conditions for FCU Command Acceptance). A transition from ROM P/E mode to ROM read mode must be made while no FCU error has been detected since FCU command processing is completed.

Figure 27.20 Procedure for Transition to ROM Read Mode

## (6) Using ROM P/E Normal Mode Transition Command

The FCU can be moved to ROM P/E normal mode in two ways: one is to set FENTRYR appropriately in ROM read mode (see section 27.6.3 (1), Transferring Firmware to the FCU RAM) and the other is to issue a normal mode transition command in ROM P/E mode (figure 27.21). The status read mode transition command and the lock bit read mode transition command can be used in the same way as the normal mode transition command.

**Figure 27.21 Procedure to Use ROM P/E Normal Mode Transition Command**

## (7) Programming

To program the ROM, use the program command. Write byte H'E8 to a ROM program/erase address in the first cycle of the program command and byte H'80 in the second cycle. Access the P bus in words from the third to 130th cycles of the command. In the third cycle, write the programming data to the start address of the target programming area. Here, the start address must be a 256-byte boundary address. After writing words to ROM program/erase addresses 127 times, write byte H'D0 to a ROM program/erase address in the 131st cycle; the FCU then starts ROM programming. Read the FRDY bit in FSTATR0 to confirm that ROM programming is completed.

If the area accessed in the third to 130th cycles includes addresses that do not need to be programmed, write H'FFFF as the programming data for those addresses. To ignore the protection provided by the lock bit during programming, set the FPROTCN bit in FPROTR to 1 before starting programming.

Notes: \*  $t_{p256}$ : Time required to write 256-byte data (see section 33, Electrical Characteristics).  
 $t_{RESW2}$ : Reset pulse width during programming and erasure (see section 33, Electrical Characteristics).

**Figure 27.22 Procedure for ROM Programming**

## (8) Erasure

To erase the ROM, use the block erase command. Write byte H'20 to a ROM program/erase address in the first cycle of the block erase command. Write byte H'D0 to an address in the target erasure block in the second cycle; the FCU then starts ROM erasure. Read the FRDY bit in FSTATR0 to confirm that ROM erasure is completed.

To ignore the protection provided by the lock bit during erasure, set the FPROTCN bit in FPROTR to 1 before starting erasure.

**Figure 27.23 Procedure for ROM Erasure**

## (9) Suspending Programming or Erasure

To suspend programming or erasure of the ROM, use the P/E suspend command. Before issuing a P/E suspend command, check that the ILGLERR, ERSERR, and PRGERR bits in FSTATR0 and the FCUERR bit in FSTATR1 are 0; that is, to ensure that programming or erasure processing is being performed correctly. Also, check that the SUSRDY bit in FSTATR1 is 1 to ensure that a suspend command is acceptable.

After issuing a P/E suspend command, read both FSTATR0 and FSTATR1 to ensure no error has occurred. If an error has occurred, at least one of the ILGLERR, PRGERR, ERSERR, and FCUERR bits is set to 1. If programming/erasure is complete within the period from when the SUSRDY bit is ensured to be 1 until a P/E suspend command is accepted, the ILGLERR bit is set to 1 as the issued command is detected as illegal. If a P/E suspend command is accepted when programming/erasure is complete, no error occurs, hence no transition to a suspended state (the RDY bit is 1 and both the ERSSPD and PRGSPD bits are 0).

Once a P/E suspend command is accepted and programming/erasure is normally suspended, the FCU enters a suspended state and that the FRDY bit is 1 and the ERSSPD or PRGSPD bit is 1. After issuing a P/E suspend and ensuring that the FCU has entered a suspend state, determine which operation to perform in the succeeding process. If a P/E resume command is issued in the succeeding process while the FCU has not entered a suspended state, an illegal command error occurs and the FCU enters a command-locked state (see section 27.9.3, Error Protection).

### Figure 27.24 Procedure for Programming/Erase Suspension

Once the FCU has entered the erasure-suspended state, blocks not for erasing can be written to. In both programming-suspended and erasure-suspended states, the FCU can be moved to ROM read mode by clearing FENTRYR.

For the operation when the FCU accepts a P/E suspend command, see section 27.6.4, Suspending Operation.

## (10) Resuming Programming or Erasure

To resume programming or erasure that has been suspended, use the P/E resume command. If the FENTRYR setting has been modified during suspension, issue a P/E resume command only after resetting FENTRYR to the previous value that was held before the P/E suspension command was issued.

**Figure 27.25 Procedure for Resuming Programming or Erasure**

## (11) Clearing Status Register 0 (FSTATR0)

To clear the ILGLERR, PRGERR, and ERSERR bits in FSTATR0, use the status register clear command. When any one of the ILGLERR, PRGER, and ERSERR bits is 1, the FCU is in command-locked state, in which the FCU only accepts the status register clear command and does not accept other commands. When the ILGLERR bit is 1, check also the value of the ROMAE, EEPAE, EEPIFE, EEPRPE, and EEPWPE bits in FASTAT. If a status register clear command is issued without clearing these bits, the ILGLERR bit is not cleared.

**Figure 27.26 Procedure for Clearing Status Register 0**

## (12) Checking Status Register 0 (FSTATR0)

The FSTATR0 value can be checked in two ways: one is to directly read FSTATR0 and the other is to read a ROM program/erase address in ROM status read mode. After an FCU command is issued that is neither a normal mode transition command nor a lock bit read mode transition command, the FCU is in ROM status read mode. In the example shown in figure 27.27, a status read mode transition command is issued to enter ROM status read mode, and then a ROM program/erase address is read to check the FSTATR0 value.

**Figure 27.27 Procedure for Checking Status Register 0**

### (13) Reading Lock Bit

Each erasure block in the user MAT has a lock bit. While the FPROTCN bit in FPROTR is 0, the erasure block whose lock bit is set to 0 cannot be programmed or erased.

The lock bit status can be checked in either memory area read mode or register read mode. In memory area read mode (the FRDMD bit in FMODER is 0), read a ROM program/erase address in ROM lock bit read mode, and the lock bit value in the specified erasure block is copied to all bits in the data read through the P bus. In register read mode (the FRDMD bit in FMODER is 1), issue a lock bit read 2 command, and the lock bit value in the specified erasure block is copied to the FLOCKST bit in FSTATR1.

**Figure 27.28 Procedure for Reading Lock Bit in Memory Area Read Mode**

Note: \*  $t_{RESW2}$ : Reset pulse width during programming and erasure (see section 33, Electrical Characteristics).

**Figure 27.29 Procedure for Reading Lock Bit in Register Read Mode**

## (14) Writing to Lock Bit

Each erasure block in the user MAT has a lock bit. To write to a lock bit, use the lock bit program command. Write byte H'77 to a ROM program/erase address in the first cycle of the lock bit program command. Write byte H'D0 to an address in the target erasure block whose lock bit is to be written to in the second cycle; the FCU then starts writing to the lock bit. Read the FRDY bit in FSTATR0 to confirm that writing is completed.

**Figure 27.30 Procedure for Writing to the Lock Bit**

To erase a lock bit, use the block erase command. While the FPROTCN bit in FPROTR is 0, the erasure block whose lock bit is set to 0 cannot be erased. Set the FPROTCN bit to 1, and then issue a block erase command to erase a lock bit. The block erase command erases all data in the specified erasure block; it is not possible to erase only the lock bit.

### 27.6.4 Suspending Operation

When a P/E suspend command is issued while ROM is being programmed or erased, the FCU suspends the programming or erasure processing. Figure 27.31 gives an overview of operation for suspending programming. Upon accepting a programming command, the FCU clears the FRDY bit in FSTATR0 to 0 and starts programming. Once the FCU enters a state where it is ready to accept a command after the start of programming, the SUSRDY bit is set to 1. If a P/E suspend command is issued, the FCU accepts the command and clears the SUSRDY bit. If the FCU accepts the command while reapplying a write pulse, the FCU continues applying the pulse. After a specified pulse application time has elapsed, the FCU completes applying the pulse, suspends programming, and sets the PRGSPD bit to 1. Once the process completes, the FCU sets the FRDY bit to 1 and enters a programming suspended state. If the FCU accepts a P/E resume command in this state, the FCU clears the FRDY and PRGSPD bits to 0 and restarts programming.

**Figure 27.31 Suspending Programming Processing**

Figure 27.32 shows the operation for suspending erasure processing in suspension-priority mode (the ESUSPMD bit in FCPSR is 0). Upon accepting an erasing command, the FCU clears the FRDY bit to 0 and starts erasing. Once the FCU enters a state where it is ready to accept a command after the start of erasing, the SUSRDY bit is set to 1. If a P/E suspend command is issued, the FCU accepts the command and clears the SUSRDY bit. If the FCU accepts the command during its erasing operation, the FCU starts a suspending process even while applying a pulse and sets the ERSSPD bit to 1. Once the suspending process completes, the FCU sets the FRDY bit to 1 and enters an erasing suspended state. If the FCU accepts a P/E resume command in this state, the FCU clears the FRDY and PRGSPD bits to 0 and restarts erasing. The operations of the FRDY, SUSRDY, and ERSSPD bits are independent of the erasure-suspended mode.

The setting for the erasure-suspended mode affects the control methods for erasure pulse. In suspend-priority mode, if the FCU accepts a P/E suspend command while applying erasure pulse A, which has not been suspended previously, the FCU suspends the pulse application and enters an erasure-suspended state. After the FCU resumes erasing by accepting a P/E resume command, if the FCU accepts a P/E suspend command while applying erasing pulse A, the FCU continues applying the pulse. After a specified pulse application time has elapsed, the FCU completes applying the pulse and enters an erasure-suspended state. Next, after the FCU accepts a P/E resume command and starts applying a new pulse B, if the FCU accepts a P/E suspend command, the FCU suspends the pulse application. In suspense-priority mode, the suspense process is given priority by suspending once every pulse application.

**Figure 27.32 Suspending Erasure Processing (Suspension-Priority Mode)**

Figure 27.33 shows how erasure processing is suspended in erasure-priority mode (with the ESUSPMD bit in FCPSR being 1). The operation for suspending erasure processing in erasure-priority mode (the ESUSPMD bit in FCPSR is 1) is equivalent to that for suspending programming processing.

In erasure-priority mode, if the FCU accepts a P/E suspend command while applying an erasing pulse, the FCU always continues applying the pulse. As processing to reapply an erasing pulse never takes place in this mode, the total time required for erasure processing is shorter than in suspension-priority mode.

**Figure 27.33 Suspending Erasure Processing (Erasure-Priority Mode)**

## 27.7 User Boot Mode

To program or erase the user MAT in user boot mode, issue FCU commands to the FCU. A user-defined boot mode can be implemented by writing to the user boot MAT a ROM programming/erasing routine that uses a desired communications interface; when this LSI is started in user boot mode after that, the user-defined boot mode is initiated. Programming/erasure of the user boot MAT is only enabled in boot mode.

### 27.7.1 User Boot Mode Initiation

When this LSI is started in user boot mode, execution starts in the embedded program stored MAT, necessary processing such as FCU firmware transfer to the FCU RAM is performed, and then execution jumps to the location indicated by the reset vector of the user boot MAT. Figure 27.34 gives an overview of the boot sequence.

**Figure 27.34 Overview of Boot Sequence in User Boot Mode**

## 27.7.2 User MAT Programming

The user MAT can be programmed by starting this LSI in user boot mode while the user MAT programming/erasing routine created by the user is stored in the user boot MAT. Be sure to copy the user MAT programming/erasing routine to the RAM and execute it in the RAM. The user boot MAT is selected in the initial state in user boot mode; be sure to switch the memory MAT to the user MAT before starting programming. If an FCU command for ROM programming or erasure is issued while the user boot MAT is selected, the FCU does not program or erase the ROM. Figure 27.35 shows an example of the user MAT programming procedure.

**Figure 27.35 Example of User MAT Programming**

## 27.8 Programmer Mode

In programmer mode, a PROM programmer can be used to perform programming/erasing via a socket adapter, just as for a discrete flash memory. Use a PROM programmer that supports the MCU device type (FZTAT1024DV3A) having on-chip Renesas 1-Mbyte flash memory.

## 27.9 Protection

There are three types of ROM programming/erasure protection: hardware, software, and error protection.

### 27.9.1 Hardware Protection

The hardware protection function disables ROM programming and erasure according to the LSI pin settings.

#### (1) Protection through FWE Pin

When a low level is applied to the FWE pin, the FWE bit in FPMON becomes 0. In this state, a 1 cannot be written to the FENTRY0 bit in FENTRYR; that is, ROM P/E mode cannot be entered, which prevents the ROM from being programmed or erased.

When the FRDY bit is 1 and the FWE pin is driven low, the FCU clears the FENTRY0 bit to disable ROM programming and erasure. If the FRDY bit in FSTATR0 has already been set to 0 before the FWE pin is driven low, the FCU continues command processing. Even while processing a command, the FCU can accept a P/E suspend command. To resume programming or erasing the ROM, reset the FENTRY0 bit to the value that was set before being cleared, and then issue a P/E resume command.

If an attempt is made to issue a programming or erasing command to the ROM against the protection through the FWE pin, the FCU detects an error and enters command-locked state.

#### (2) Protection through Mode Pins

While the on-chip ROM is disabled, ROM programming, erasing, and reading are disabled. For the operating modes set through the mode pins of this LSI, refer to section 3, MCU Operating Modes. In user boot mode or user program mode, the user boot MAT cannot be programmed or erased.

## 27.9.2 Software Protection

The software protection function disables ROM programming and erasure according to the control register settings or the lock bit settings in the user MAT. If an attempt is made to issue a programming or erasing command to the ROM against software protection, the FCU detects an error and enters command-locked state.

### (1) Protection through FENTRYR

When the FENTRY0 bit is 0, the 1-Mbyte ROM (read addresses: H'00000000 to H'000FFFFF; program/erase addresses: H'80800000 to H'808FFFFF) is set to ROM read mode. In ROM read mode, the FCU does not accept commands, so ROM programming and erasure are disabled. If an attempt is made to issue an FCU command in ROM read mode, the FCU detects an illegal command error and enters command-locked state (see section 27.9.3, Error Protection).

### (2) Protection through Lock Bits

Each erasure block in the user MAT has a lock bit. When the FPROTCN bit in FPROTR is 0, the erasure block whose lock bit is set to 0 cannot be programmed or erased. To program or erase the erasure block whose lock bit is 0, set the FPROTCN bit to 1. If an attempt is made to issue a programming or erasing command against protection by lock bits, the FCU detects an programming/erasure error and enters command-locked state (see section 27.9.3, Error Protection).

### 27.9.3 Error Protection

The error protection function detects an illegal FCU command issued, an illegal access, or an FCU malfunction, and disables FCU command acceptance (command-locked state). While the FCU is in command-locked state, the ROM cannot be programmed or erased. To cancel command-locked state, issue a status register clear command while FASTAT is H'10.

While the CMDLKIE bit in FAEINT is 1, a flash interface error (FIFE) interrupt is generated if the FCU enters command-locked state (the CMDLK bit in FASTAT becomes 1). While the ROMAEINT bit in FAEINT is 1, an FIFE interrupt is generated if the ROMAE bit in FASTAT becomes 1.

Table 27.14 shows the error protection types dedicated for the ROM, those used in common by the ROM and the FLD, and the status bit values (the ILGLERR, ERSERR, and PRGERR bits in FSTATR0, the FCUERR bit in FSTATR1, and the ROMAE bit in FASTST) after each error detection. If the FCU enters command-locked state due to a command other than a suspend command issued during programming or erasure processing, the FCU continues programming or erasing the ROM. In this state, the P/E suspend command cannot suspend programming or erasure. If a command is issued in command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set due to the previous error detection.

**Table 27.14 Error Protection Types**

| Error                 | Description                                                                              | ILGLERR | ERSERR | PRGERR | FCUERR | ROMAE |
|-----------------------|------------------------------------------------------------------------------------------|---------|--------|--------|--------|-------|
| FENTRYR setting error | The value set in FENTRYR is not H'0001, H'0002, H'0008, H'0010, or H'0080.               | 1       | 0      | 0      | 0      | 0     |
|                       | The FENTRYR setting for resuming operation does not match that for suspending operation. | 1       | 0      | 0      | 0      | 0     |

| Error                 | Description                                                                                                                                            | ILGLERR | ERSERR | PRGERR | FCUERR | ROMAE |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|---------|--------|--------|--------|-------|
| Illegal command error | An undefined code has been specified in the first cycle of an FCU command.                                                                             | 1       | 0      | 0      | 0      | 0     |
|                       | The value specified in the last of the multiple cycles of an FCU command is not H'D0.                                                                  | 1       | 0      | 0      | 0      | 0     |
|                       | The peripheral clock specified in PCKAR is not in the range from 1 to 100 MHz.                                                                         | 1       | 0      | 0      | 0      | 0     |
|                       | The command issued during programming or erasure is not a suspend command.                                                                             | 1       | 0      | 0      | 0      | 0     |
|                       | A suspend command has been issued during operation that is neither programming nor erasure.                                                            | 1       | 0      | 0      | 0      | 0     |
|                       | A suspend command has been issued in suspended state.                                                                                                  | 1       | 0      | 0      | 0      | 0     |
|                       | A resume command has been issued in a state that is not a suspended state.                                                                             | 1       | 0      | 0      | 0      | 0     |
|                       | A programming or erasing command (program, lock bit program, block erase) has been issued in programming-suspended state.                              | 1       | 0      | 0      | 0      | 0     |
|                       | A block erase command has been issued in erasure-suspended state.                                                                                      | 1       | 0      | 0      | 0      | 0     |
|                       | A program, lock bit program, or non-interleaved program command has been issued for an erasure-suspended area in erasure-suspended state.              | 1       | 0      | 0      | 0      | 0     |
| Erasure error         | The value specified in the second cycle of a program command is not H'80.                                                                              | 1       | 0      | 0      | 0      | 0     |
|                       | A command has been issued in command-locked state.                                                                                                     | 1       | 0/1    | 0/1    | 0/1    | 0/1   |
| Programming error     | An error has occurred during erasure processing.                                                                                                       | 0       | 1      | 0      | 0      | 0     |
|                       | A block erase command has been issued for the erasure block whose lock bit is set to 0 while the FPROTCN bit in FPROTR is 0.                           | 0       | 1      | 0      | 0      | 0     |
| Programming error     | An error has occurred during programming processing.                                                                                                   | 0       | 0      | 1      | 0      | 0     |
|                       | A program, lock bit program, or program command has been issued for the erasure block whose lock bit is set to 0 while the FPROTCN bit in FPROTR is 0. | 0       | 0      | 1      | 0      | 0     |

| Error            | Description                                                                                                                                                        | ILGLERR | ERSERR | PRGERR | FCUERR | ROMAE |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|--------|--------|--------|-------|
| FCU error        | An error has occurred during CPU processing in the FCU.                                                                                                            | 0       | 0      | 0      | 1      | 0     |
| ROM access error | A read access command has been issued to addresses H'80800000 to H'808FFFFFF while FENTRY0 = 1 in ROM P/E normal mode.                                             | 1       | 0      | 0      | 0      | 1     |
|                  | An access command has been issued to addresses H'80800000 to H'808FFFFFF while FENTRY0 = 0                                                                         | 1       | 0      | 0      | 0      | 1     |
|                  | A read access command has been issued to addresses H'00000000 to H'001FFFFFF while the FENTRYR register value is not H'0000                                        | 1       | 0      | 0      | 0      | 1     |
|                  | A ROM programming or erasing command (interleaved program, lock bit program, or block erase command) has been issued while the user boot MAT is selected.          | 1       | 0      | 0      | 0      | 1     |
|                  | An access command has been issued to an address other than the addresses for ROM programming/erasure H'80800000 to H'80807FFF while the user boot MAT is selected. | 1       | 0      | 0      | 0      | 1     |

## 27.10 Usage Notes

### 27.10.1 Switching between User MAT and User Boot MAT

The user MAT and user boot MAT are allocated to the same address area. If the ROM area is accessed during switching between the user MAT and user boot MAT, an unexpected MAT may be accessed because the number of cycles required to access the ROM area depends on the internal bus status. When the ROM cache function is enabled, the previously stored data is left in the ROM cache even after MAT switching; note that a cache hit may occur when a newly selected MAT is accessed at the same address as the data stored in the cache. To avoid such unexpected behavior, take the following steps before and after MAT switching.

1. Modifying interrupt settings before MAT switching

There are two ways to avoid ROM area access due to an interrupt during MAT switching: one is to specify the interrupt vector fetch destination outside the ROM area through the vector base register (VBR) setting in the CPU, and the other is to mask interrupts. Note that NMI interrupts cannot be masked in this LSI; when masking interrupts to avoid ROM area access in this LSI, design the system so that no NMI is generated during MAT switching.

2. Switching between MATs through a program outside the ROM area

To avoid CPU instruction fetch in the ROM area during MAT switching, execute the MAT switching processing outside the ROM area.

3. Performing dummy read of ROMMAT

After writing to ROMMAT to switch between MATs, perform a dummy read of ROMMAT to ensure that the register write is completed.

4. Flushing the ROM cache after MAT switching

Disable (flush) the instructions or data in the ROM cache by writing a 1 to the RCF bit in RCCR.

**Figure 27.36 Example of MAT Switching Steps**

### 27.10.2 State in which Interrupts are Ignored

In the following mode or period, the AUD is in module standby mode and cannot operate. The NMI or maskable interrupt requests are ignored.

- Boot mode
- The program in the embedded program stored MAT is being executed immediately after the LSI is started in user boot mode

### 27.10.3 Programming-/Erasure-Suspended Area

The data stored in the programming-suspended or erasure-suspended area is undetermined. To avoid malfunction due to undefined read data, ensure that no instruction is executed or no data is read from the programming-suspended or erasure-suspended area.

To avoid instruction fetch from the programming-suspended or erasure-suspended area, which may be caused by prefetch by the ROM cache, ensure that no instruction is fetched within 16 bytes from the start address of the programming-suspended or erasure-suspended area.

During ROM cache prefetch, the destination of a branch instruction is also accessed. The destination must not be in the programming-suspended or erasure-suspended area.

### 27.10.4 Compatibility with Programming/Erasing Program of Conventional F-ZTAT SH Microcomputers

The flash memory programming/erasing program used for conventional F-ZTAT SH microcontrollers does not work with this LSI.

### 27.10.5 FWE Pin State

Ensure that the FWE pin level does not change during programming or erasure. If the FWE level goes low, the current programming or erasure terminates abnormally and the FRDY bit is set to 1 (the erasure or programming error bit in FASTATRO is set), and then FENTRYR is cleared. To reprogram ROM, do it after erasing data with the FWE pin at the high level.

In a transition from single-chip mode to user program mode, issue an FCU command after driving the FWE pin high, making sure that the FWE bit in FPMON is set to 1, and setting the FENTRYR register.

In a transition from user program mode to single-chip mode, drive the FWE pin low after ROM programming is completed, making sure that the FRDY bit in FSTATR0 is set to 1, and clearing the FENTRYR register.

For ROM protection in a mode that begins with the FWE pin at the high level, drive the FWE pin low tMDH1 after the reset is cleared.

Cancel ROM protection using the same steps as the transition from single-chip mode to user program mode, and set ROM protection using the same steps as the transition from user program mode to single-chip mode.

### 27.10.6 Reset during Programming or Erasure

To reset the FCU by setting the FRESET bit in the FRESETR register during programming or erasure, hold the FCU in the reset state for a period of  $t_{RESW2}$  (see section 33, Electrical Characteristics). Since a high voltage is applied to the ROM during programming and erasure, the FCU has to be held in the reset state long enough to ensure that the voltage applied to the memory unit has dropped. Do not read from the ROM while the FCU is in the reset state.

When a power-on reset is generated by asserting the  $\overline{RES}$  pin during programming or erasure of the flash memory, hold the reset state for a period of  $t_{RESW2}$  (see section 33, Electrical Characteristics). In a power-on reset, not only does the voltage applied to the memory unit have to drop, but the power supply for the ROM and its internal circuitry also have to be initialized. Thus, the reset state must be maintained over a longer period than in the case of resetting the FCU.

When executing a power-on reset by asserting the  $\overline{RES}$  pin or the FCU reset with the FRESET bit set in FRESETR during programming/erasure, all data including a lock bit of a programming/erasure target area are undefined.

While programming or erasure is performed, do not generate an internal reset caused by WDT counter overflow. A reset caused by WDT cannot ensure a sufficient time required for voltage drop for the memory unit, initialization of the power supply for the ROM, or initialization of its internal circuit.

### 27.10.7 Suspension by Programming/Erasure Suspension

When suspending programming/erasure processing with the programming/erasure suspend command, make sure to complete the operations with the resume command.

### 27.10.8 Prohibition of Additional Programming

One area cannot be programmed twice in succession. To program an area that has already been programmed, be sure to erase the area before reprogramming.

### 27.10.9 Allocation of Interrupt Vectors during Programming and Erasure

Generation of an interrupt during programming and erasure can lead to fetching from the vector in the flash memory (ROM). For this reason, prepare the interrupt vector table and the interrupt processing routines in areas other than the flash memory (ROM).

### 27.10.10 Items Prohibited during Programming and Erasure

High voltages are applied within the flash memory (ROM) during programming and erasure. To prevent destruction of the chip, ensure that the following operations are not performed during programming and erasure.

- Cutting off the power supply
- Transitions to software standby mode
- Read access to the flash memory by the CPU, DMAC or DTC
- Writing a new value to the FRQCR register
- Setting the PCKAR register for a different frequency from that of P $\phi$ .

### 27.10.11 Abnormal Ending of Programming or Erasure

A lock bit may be set to 0 (in the protected state) due to a reset, an FCU reset by the FRESET bit in the FRESETR register, a transition to the command-locked state because an error has been detected, or programming or erasure not being completed normally.

If this is the case, issue a block erase command to erase the lock bit while the FPROTR.FPROTCN bit is set to 1. After that, repeat the programming until it is finished.

## Section 28 Data Flash (FLD)

This LSI includes 32 Kbytes of flash memory (FLD) for storing data. The FLD has the following features.

### 28.1 Features

- Flash-memory MATs  
Data MAT: 32 Kbytes (8 Kbytes × 4 blocks)

**Figure 28.1 Memory MAT Configuration in FLD**

- Reading through the peripheral bus (P bus)

The data MAT can be read through the P bus. Reading programs can be executed on the on-chip RAM or on-chip ROM.

- Programming and erasing methods

The FLD has a dedicated sequencer (FCU) for reprogramming of the flash-memory MATs. The ROM is programmed and erased by issuing commands to the FCU.

- BGO (background operation) function

1. The CPU can execute programs located in areas other than the ROM while the FCU is programming or erasing the ROM.
2. A program located in ROM can be executed while the FCU is programming or erasing the data flash.

- Suspending and resuming operation

After the FCU has suspended programming or erasing the ROM, and the CPU has executed the program in the ROM, the FCU can resume programming or erasure of the ROM. These operations are called suspension (suspend processing) and resumption (resume processing).

Figure 28.2 Block Diagram of FLD

- Programming/erasing unit

The data MAT is programmed in 8-byte or 128-byte units and erased in block units (8 Kbytes) in user mode, user program mode, and user boot mode. In boot mode, the data MAT is programmed in 256-Kbyte units and erased in block units (8 Kbytes). The product information MAT is read-only memory and cannot be programmed or erased.

Figure 28.3 shows the block configuration of the data MAT of this LSI. The data MAT is divided into four 8-Kbyte blocks (DB00 to DB03).

**Figure 28.3 Block Configuration of Data MAT**

- Blank check function

If data is read from erased FLD by the CPU, undefined values are read. Using blank check command of the FCU allows checking of whether the FLD is erased (in a blank state). Either an 8 Kbytes (1 erasure block) or 8 bytes of area can be checked by a single execution of the blank check command.

Blank checking proceeds for areas where erasure has been completed normally to confirm that the data have actually been erased. When erasure or programming in progress is stopped (e.g. by input of the reset signal or shutting down the power), blank checking cannot be used to check whether the data have actually been erased or written.

- Four types of on-board programming modes

- Boot mode

The data MAT can be programmed using the SCI. The bit rate for SCI communications between the host and the LSI can be automatically adjusted.

- User mode/user program mode

The data MAT can be programmed with a desired interface. The user mode includes the MCU extended mode and MCU single-chip mode (modes 2 and 3) in which the on-chip ROM is enabled.

- USB boot mode

A mode for programming via the USB

- User boot mode

The data MAT can be programmed with a desired interface. To make a transition to this mode, a reset is needed.

- Protection modes

This LSI supports two modes to protect memory against programming, erasing, or reading: hardware protection by the levels on the mode pins and software protection by the setting of the FENTRYD bit, EEPRE0 register, or EEPWE0 register. The FENTRYD bit enables or disables data MAT programming or erasure by the FCU. EEPRE0 controls protection of each data MAT block against reading, and EEPWE0 controls protection against programming and erasure.

The LSI also provides a function to suspend programming or erasure when abnormal operation is detected during programming or erasure. In addition, the LSI provides a function to protect the FLD against instruction fetch attempted by the CPU.

- Programming and erasing time and count

Refer to section 33, Electrical Characteristics.

## 28.2 Input/Output Pins

Table 28.1 shows the input/output pins used for the FLD. The combination of MD1 and MD0 pin levels determines the FLD programming mode (see section 28.4, Overview of FLD-Related Modes). In boot mode, programming and erasing the FLD can be performed by the host via the PA3/RxD1 and PA4/TxD1 pins (refer to section 28.5, Boot Mode).

**Table 28.1 Pin Configuration**

| Pin Name                       | Symbol                  | I/O    | Function                                                                      |
|--------------------------------|-------------------------|--------|-------------------------------------------------------------------------------|
| Power-on reset                 | $\overline{\text{RES}}$ | Input  | This LSI enters the power-on reset state when this signal goes low.           |
| Mode                           | MD1, MD0                | Input  | These pins specify the operating mode.                                        |
| Receive data in SCI channel 1  | PA3/RxD1                | Input  | Receives data through SCI channel 1 (communications with host)                |
| Transmit data in SCI channel 1 | PA4/TxD1                | Output | Transmits data through SCI channel 1 (communications with host)               |
| Pull-up control                | PUPD (PB15)             | Output | Pull-up control (used in USB boot mode)                                       |
| USB data                       | USD+<br>USD-            | I/O    | USD signal from the USB with a transceiver (used in USB boot mode)            |
| USB cable connection monitor   | VBUS                    | Input  | Detects connection and disconnection of the USB cable (used in USB boot mode) |
| USB clock select               | PB14                    | Input  | Selects the clock supplied by the USB (used in USB boot mode)                 |

## 28.3 Register Descriptions

Table 28.2 shows the FLD-related registers. Some of these registers have ROM-related bits, but this section only describes the FLD-related bits. For the registers consisting of bits used by the ROM and FLD in common (FCURAME, FSTATR0, FSTATR1, FRESETR, FCMDR, and FCPSR) and the ROM-dedicated bits, refer to section 27.3, Register Descriptions. The FLD-related registers are initialized by a power-on reset.

**Table 28.2 Register Configuration**

| Register Name                                | Symbol    | R/W <sup>*1</sup>   | Initial Value        | Address    | Access Size |
|----------------------------------------------|-----------|---------------------|----------------------|------------|-------------|
| Flash mode register                          | FMODR     | R/W                 | H'00                 | H'FFFFA802 | 8           |
| Flash access status register                 | FASTAT    | R/(W) <sup>*2</sup> | H'00                 | H'FFFFA810 | 8           |
| Flash access error interrupt enable register | FAEINT    | R/W                 | H'9F                 | H'FFFFA811 | 8           |
| FLD read enable register 0                   | EEPRE0    | R/(W) <sup>*3</sup> | H'0000               | H'FFFFA840 | 8, 16       |
| FLD program/erase enable register 0          | EEPWE0    | R/(W) <sup>*3</sup> | H'0000               | H'FFFFA850 | 8, 16       |
| FCU RAM enable register                      | FCURAME   | R/(W) <sup>*3</sup> | H'0000               | H'FFFFA854 | 8, 16       |
| Flash status register 0                      | FSTATR0   | R                   | H'80 <sup>*5</sup>   | H'FFFFA900 | 8, 16       |
| Flash status register 1                      | FSTATR1   | R                   | H'00 <sup>*5</sup>   | H'FFFFA901 | 16          |
| Flash P/E mode entry register                | FENTRYR   | R/(W) <sup>*4</sup> | H'0000 <sup>*5</sup> | H'FFFFA902 | 8, 16       |
| Flash reset register                         | FRESETR   | R/(W) <sup>*3</sup> | H'0000               | H'FFFFA906 | 8, 16       |
| FCU command register                         | FCMDR     | R                   | H'FFFF <sup>*5</sup> | H'FFFFA90A | 8, 16       |
| FCU processing switch register               | FCPSR     | R/W                 | H'0000 <sup>*5</sup> | H'FFFFA918 | 8, 16       |
| FLD blank check control register             | EEPBCCNT  | R/W                 | H'0000 <sup>*5</sup> | H'FFFFA91A | 8, 16       |
| FLD blank check status register              | EEPBCSTAT | R                   | H'0000 <sup>*5</sup> | H'FFFFA91E | 8, 16       |
| Peripheral clock notification register       | PCKAR     | R/W                 | H'0000 <sup>*5</sup> | H'FFFFA938 | 8, 16       |

- Notes:
1. In on-chip ROM disabled mode, the bits of the FLD-related registers are always read as 0 and writing to them is ignored.
  2. This register consists of the bits where only 0 can be written to clear the flags and the read-only bits.
  3. This register can be written to only when a specified value is written to the upper byte in word access. The data written to the upper byte is not stored in the register.
  4. This register can be written to only when a specified value is written to the upper byte in word access; the register is initialized when a value not allowed for the register is written to the upper byte. The data written to the upper byte is not stored in the register.
  5. This register can be initialized by a power-on reset, or by setting the FRESET bit of FRESETR to 1.

### 28.3.1 Flash Mode Register (FMODR)

FMODR specifies an operating mode for the FCU. In on-chip ROM disabled mode, the FMODR bits are always read as H'00, and writing to them is ignored. FMODR can be initialized by a power-on reset.

This bit specifies the FLD lock bit read mode transition or blank check processing in the FLD (see section 28.6.1, FCU Command List, 28.6.3, FCU Command Usage), whereas this bit must be set to specify the read method for the lock bits in the ROM (see section 27, Flash Memory (ROM)).<br><br>0: Memory area read mode<br><br>This mode is selected to enter the FLD lock bit read mode. Since the FLD has no lock bits, reading an FLD area results in an undefined value.<br><br>1: Register read mode<br><br>To make the blank check command available for use, register read mode is set. |

## 28.3.2 Flash Access Status Register (FASTAT)

FASTAT indicates the access error status for the ROM and FLD. In on-chip ROM disabled mode, FASTAT is read as H'00 and writing to it is ignored. If any bit in FASTAT is set to 1, the FCU enters command-locked state (see section 28.7.3, Error Protection). To cancel command-locked state, set FASTAT to H'10, and then issue a status-clear command to the FCU. FASTAT is initialized by a power-on reset.

### 28.3.3 Flash Access Error Interrupt Enable Register (FAEINT)

FAEINT enables or disables output of flash interface error (FIFE) interrupt requests. In on-chip ROM disabled mode, FAEINT is read as H'00 and writing to it is ignored. FAEINT is initialized by a power-on reset.

### 28.3.4 FLD Read Enable Register 0 (EEPRE0)

EEPRE0 enables or disables read access to blocks DB00 to DB03 (see figure 28.3) in the data MAT. In on-chip ROM disabled mode, EEPRE0 is read as H'0000 and writing to it is ignored. EEPRE0 is initialized by a power-on reset.

### 28.3.5 FLD Program/Erase Enable Register 0 (EEPWE0)

EEPWE0 enables or disables programming and erasure of blocks DB00 to DB03 (see figure 28.3) in the data MAT. In on-chip ROM disabled mode, EEPWE0 is read as H'0000 and writing to it is ignored. EEPWE0 is initialized by a power-on reset.

28.3.6 Flash P/E Mode Entry Register (FENTRYR)

FENTRYR specifies the P/E mode for the ROM or FLD. To specify the P/E mode for the ROM or FLD so that the FCU can accept commands, set either FENTRYD or FENTRY0 to 1. In on-chip ROM disabled mode, FENTRYR is read as H'0000 and writing to it is ignored. FENTRYR is initialized by a power-on reset, or setting the FRESET bit of FRESETR to 1.

In access to the FENTRYR for a mode transition of the FCU, write to the register and then read it. Proceed with programming, erasure or reading of the FLD after confirming the register setting.

Note: \* Write data is not retained.

### 28.3.7 FLD Blank Check Register (EEPBCCNT)

EEPBCCNT specifies the addresses and sizes of the target areas to be checked by the blank check command. In on-chip ROM disabled mode, EEPBCCNT is read as H'0000, and writing to it is ignored. EEPBCCNT is initialized by a power-on reset, or by setting the FRESET bit of FRESETR to 1.

### 28.3.8 FLD Blank Check Status Register (EEPBCSTAT)

EEPBCSTAT stores check results by executing the blank check command. In on-chip ROM disabled mode, EEPBCSTAT is read as H'0000, and writing to it is ignored. EEPBCSTAT is initialized by a power-on reset, or by setting the FRESET bit of FRESETR to 1.

## 28.4 Overview of FLD-Related Modes

Figure 28.4 shows the FLD-related mode transition in this LSI. For the relationship between the LSI operating modes and the MD1 and MD0 pin settings, refer to section 3, MCU Operating Modes.

**Figure 28.4 FLD-Related Mode Transition**

- The FLD cannot be read, programmed, or erased in on-chip ROM disabled mode.
- The data MAT can be read, programmed, and erased on the board in user mode, user program mode, user boot mode, boot mode, and USB boot mode.
- In user mode, the ROM cannot be programmed or erased but the FLD can be programmed and erased. While the FLD is being programmed or erased, the ROM can be read. Therefore, the user can program the FLD while executing an application program in the ROM protected against programming and erasure.

Table 28.3 compares programming- and erasure-related items for the boot mode, user mode, user program mode, user boot mode, and USB boot mode.

**Table 28.3 Comparison of Programming Modes**

| Item                            | Boot Mode                   | User Mode               | User Program Mode       | User Boot Mode              | USB Boot Mode               |
|---------------------------------|-----------------------------|-------------------------|-------------------------|-----------------------------|-----------------------------|
| Programming/erasure environment |                             |                         | On-board programming    |                             |                             |
| Programming/erasure enabled MAT | Data MAT                    | Data MAT                | Data MAT                | Data MAT                    | Data MA                     |

| Entire area erasure             | Available (automatic)       | Available               | Available               | Available                   | Available (automatic)       |
| Block erasure                   | Available* <sup>1</sup>     | Available               | Available               | Available                   | Available* <sup>1</sup>     |
| Programming data transfer       | From host via SCI           | From any device via RAM | From any device via RAM | From any device via RAM     | From host via USB           |
| Reset-start MAT                 | Embedded program stored MAT | User MAT                | User MAT                | User boot MAT* <sup>2</sup> | Embedded program stored MAT |

Notes: 1. The entire area is erased when the LSI is started. After that, a specified block can be erased.

2. After the LSI is started in the embedded program stored MAT and the boot program provided by Renesas Corp. is executed, execution starts from the location indicated by the reset vector of the user boot MAT.

- In boot mode or USB boot mode, the user MAT and user boot MAT in the ROM and the data MAT are all erased immediately after the LSI is started. The data MAT can then be programmed from the host via the SCI. The data MAT can also be read after this entire area erasure.
- In user boot mode, a boot operation with a desired interface can be implemented through mode pin settings different from those in user mode or user program mode.

## 28.5 Boot Mode

To program or erase the data MAT in boot mode, send control commands and programming data from the host. For the system configuration and settings in boot mode, refer to section 27, Flash Memory (ROM). This section describes only the commands dedicated for the FLD.

### 28.5.1 Inquiry/Selection Host Commands

Table 28.4 shows the inquiry/selection host commands dedicated to the FLD. The data MAT inquiry and data MAT information inquiry commands are used in the step for inquiry regarding the MAT programming information shown in figure 27.11 in section 27.5.5, Inquiry/Selection Host Command Wait State.

**Table 28.4 Inquiry/Selection Host Commands (for FLD only)**

| Host Command Name            | Function                                                                   |
|------------------------------|----------------------------------------------------------------------------|
| Data MAT inquiry             | Inquires regarding the availability of user MAT                            |
| Data MAT information inquiry | Inquires regarding the number of data MATs and the start and end addresses |

Each host command is described in detail below. The "command" in the description indicates a command sent from the host to this LSI and the "response" indicates a response sent from this LSI to the host. The "checksum" is byte-size data calculated so that the sum of all bytes to be sent by this LSI becomes H'00.

## (1) Data MAT Inquiry

In response to a data MAT inquiry command sent from the host, this LSI returns the information concerning the availability of data MATs.

Command 

|      |
|------|
| H'2A |
|------|

Response 

|      |      |              |     |
|------|------|--------------|-----|
| H'3A | Size | Availability | SUM |
|------|------|--------------|-----|

### [Legend]

Size (1 byte): Total number of characters in the availability field (fixed at 1)

Availability (1 byte): Availability of data MATs (fixed at H'01)

H'00: No data MAT is available

H'01: Data MAT is available

SUM (1 byte): Checksum

## (2) Data MAT Information Inquiry

In response to a data MAT information inquiry command sent from the host, this LSI returns the number of data MATs and their addresses.

Command

|      |
|------|
| H'2B |
|------|

Response

| H'3B              | Size | MAT count |
|-------------------|------|-----------|
| MAT start address |      |           |
| MAT end address   |      |           |
| MAT start address |      |           |
| MAT end address   |      |           |
| :                 |      |           |
| MAT start address |      |           |
| MAT end address   |      |           |
| SUM               |      |           |

[Legend]

Size (1 byte): Total number of bytes in the MAT count, MAT start address, and MAT end address fields

MAT count (1 byte): Number of data MATs (consecutive areas are counted as one MAT)

MAT start address (4 bytes): Start address of a data MAT

MAT end address (4 bytes): End address of a data MAT

SUM (1 byte): Checksum

The information concerning the block configuration in the data MAT is included in the response to the erasure block information inquiry command (refer to section 27.5.5, Inquiry/Selection Host Command Wait State).

## 28.5.2 Programming/Erasing Host Commands

Table 28.5 shows the programming/erasing host commands dedicated to the FLD. FLD-dedicated host commands are provided only for checksum and blank check; the programming, erasing, and reading commands are used in common for the ROM and FLD.

To program the data MAT, issue from the host a user MAT programming selection command and then a 256-byte programming command specifying a data MAT address as the programming address. To erase the data MAT, issue an erasure selection command and then a block erasure command specifying an erasure block in the data MAT. The information concerning the erasure block configuration in the data MAT is included in the response to the erasure block information inquiry command. To read data from the data MAT, select the user MAT through a memory read command specifying a data MAT address as the read address.

For the user MAT programming selection, user boot MAT programming selection, 256-byte programming, erasure selection, block erasure selection, and memory read commands, refer to section 27.5.6, Programming/Erasing Host Command Wait State. For the erasure block information inquiry command, refer to section 27.5.5, Inquiry/Selection Host Command Wait State.

**Table 28.5 Programming/Erasure Host Commands (for FLD)**

| Host Command Name    | Function                                        |
|----------------------|-------------------------------------------------|
| Data MAT checksum    | Performs checksum verification for the data MAT |
| Data MAT blank check | Checks whether the data MAT is blank            |

Each host command is described in detail below. The "command" in the description indicates a command sent from the host to this LSI and the "response" indicates a response sent from this LSI to the host. The "checksum" is byte-size data calculated so that the sum of all bytes to be sent by this LSI becomes H'00.

**(1) Data MAT Checksum**

In response to a data MAT checksum command sent from the host, this LSI sums the data MAT data in byte units and returns the result (checksum).

Command 

|      |
|------|
| H'61 |
|------|

Response 

|      |      |              |     |
|------|------|--------------|-----|
| H'71 | Size | MAT checksum | SUM |
|------|------|--------------|-----|

[Legend]

Size (1 byte):      Number of bytes in the MAT checksum field (fixed at 4)

MAT checksum (4 bytes):      Checksum of the data MAT data

SUM (4 bytes):      Checksum (for the response data)

**(2) Data MAT Blank Check**

In response to a data MAT blank check command sent from the host, this LSI checks whether the data MAT is completely erased. When the data MAT is completely erased, this LSI returns a response (H'06). If the user MAT has an unerased area, this LSI returns an error response (sends H'E2 and H'52 in that order).

Command 

|      |
|------|
| H'62 |
|------|

Response 

|      |
|------|
| H'06 |
|------|

Error response 

|      |      |
|------|------|
| H'E2 | H'52 |
|------|------|

## 28.6 User Mode, User Program Mode, and User Boot Mode

### 28.6.1 FCU Command List

To program or erase the data MAT in user mode, user program mode, or user boot mode, issue FCU commands to the FCU. Table 28.6 is a list of FCU commands for FLD programming and erasure.

**Table 28.6 FCU Command List (FLD-Related Commands)**

| Command                                         | Function                                                                                     |
|-------------------------------------------------|----------------------------------------------------------------------------------------------|
| Normal mode transition                          | Moves to the normal mode (see section 28.6.2, Conditions for FCU Command Acceptance).        |
| Status read mode transition                     | Moves to the status read mode (see section 28.6.2, Conditions for FCU Command Acceptance).   |
| Lock bit read mode transition (lock bit read 1) | Moves to the lock bit read mode (see section 28.6.2, Conditions for FCU Command Acceptance). |
| Program                                         | Programs FLD (in 8-byte or 128-byte units).                                                  |
| Block erase                                     | Erases FLD (in block units).                                                                 |
| P/E suspend                                     | Suspends programming or erasure.                                                             |
| P/E resume                                      | Resumes programming or erasure.                                                              |
| Status register clear                           | Clears the IRGERR, ERSERR, and PRGERR bits in FSTATR0 and cancels the command-locked state.  |
| Blank check                                     | Checks if a specified area is erased (blank).                                                |
| Peripheral clock notification                   | Specifies the peripheral clock frequency                                                     |

FCU commands other than the program command and blank check command are also used for ROM programming and erasure. When the blank check command is issued to the ROM, the lock bits in the ROM are read out.

To issue a command to the FCU, access the FLD area through the P bus. Table 28.7 shows the FCU command formats for the program command and blank check command. For the other command formats, refer to section 27.6.1, FCU Command List. When a P-bus access, as shown in table 28.7, is made under specified conditions, the FCU performs processing specified by a selected command. For the conditions for the FCU command acceptance, refer to section 28.6.2, Conditions for FCU Command Acceptance. For details of command usage, refer to section 28.6.3, FCU Command Usage.

When the FRDMD bit is set to 0 (memory area read mode), if the data in the first cycle of an FCU command is determined as H'71, the FCU accepts the lock bit read mode transition command. Since the FLD has no lock bits, making P-bus access after a transition to the lock bit read mode results in undefined read data. The FCU detects no access violation error when the undefined data is read. When the FRDMD bit is set to 1 (register read mode), if the data in the first cycle of an FCU command is determined as H'71, the FCU enters a waiting state to wait for the command in the second cycle (H'D0) of the blank check command. At this stage, if H'D0 is written into an FLD area by a P-bus write access, the FCU detects it and starts performing the blank check processes specified by the set values in the EEPBCCNT register, and once the check completes the FCU writes check results into the EEPBCSTAT register.

There are two suspending modes to be initiated by the P/E suspend command; the suspension-priority mode and erasure-priority mode. For details of each mode, refer to section 27.6.4, Suspending Operation.

**Table 28.7 FCU Command Formats (for FLD only)**

| Command                                | Number of Bus Cycles | First Cycle |      | Second Cycle |      | Third Cycle |      | Fourth Cycle to Cycle N + 2 |      | Cycle N + 3 |      |
|----------------------------------------|----------------------|-------------|------|--------------|------|-------------|------|-----------------------------|------|-------------|------|
|                                        |                      | Address     | Data | Address      | Data | Address     | Data | Address                     | Data | Address     | Data |
| Program (8-byte programming: N = 4)    | 7                    | EA          | H'E8 | EA           | H'04 | WA          | WD1  | EA                          | WDn  | EA          | H'D0 |
| Program (128-byte programming: N = 64) | 67                   | EA          | H'E8 | EA           | H'40 | WA          | WD1  | EA                          | WDn  | EA          | H'D0 |
| Blank check                            | 2                    | EA          | H'71 | BA           | H'D0 | —           | —    | —                           | —    | —           | —    |

**[Legend]**

EA: FLD area address

An arbitrary address within the range of H'8010000 to H'80107FFF

WA: The start address of write data

BA: The address of an FLD erasure block

(An arbitrary address in the erase target block)

WDn: n-th word of programming data (n = 1 to N)

## 28.6.2 Conditions for FCU Command Acceptance

The FCU determines whether to accept a command depending on the FCU mode or status. Figure 28.5 is an FCU mode transition diagram.

**Figure 28.5 FCU Mode Transition Diagram (FLD-Related Modes)**

### (1) ROM P/E Mode

The FCU can accept ROM programming and erasing commands in this mode. The FLD cannot be read. The FCU enters this mode when the FENTRYD bit is set to 0 and the FENTRY0 bit is set to 1 in FENTRYR. For details of this mode, refer to section 27.6.2, Conditions for FCU Command Acceptance.

### (2) ROM/FLD Read Mode

The FLD can be read through the HPB, and the ROM can be read through the ROM cache at a high speed. The FCU does not accept commands. The FCU enters this mode when the FENTRY0 bit is set to 0 and the FENTRYD bit in FENTRYR is set to 0.

### (3) FLD P/E Mode

- FLD P/E normal mode

The FCU enters this mode when the FENTRYD bit is set to 1 and the FENTRY0 bit is set to 0 in ROM/FLD read mode or ROM P/E mode, or when a normal mode transition command is accepted in FLD P/E mode. Table 28.8 shows the commands that can be accepted in this mode. If the FLD area is read through the P bus, an FLD access error occurs and the FCU enters the command-locked state.

- FLD status read mode

The FCU enters this mode when the FCU accepts a command that is neither the normal mode transition command nor the lock bit read mode transition command in FLD P/E mode. The FLD status read mode includes the state in which the FRDY bit in FSTATR0 is 0 and the command-locked state after an error has occurred. Table 28.8 shows the commands that can be accepted in this mode. If the FLD area is read through the P bus, the FSTATR0 value is read.

- FLD lock bit read mode

The FCU enters this mode when the FCU accepts a lock bit read mode transition command in FLD P/E mode. Table 28.8 shows the commands that can be accepted in this mode. Since the FLD has no lock bits, reading an FLD area via the P-bus results in an undefined value. However, no access violation occurs in this case. High-speed read operation is available for ROM.

Table 28.8 shows the correlation between each FCU mode/state and its acceptable commands. When an unacceptable command is issued, the FCU enters the command-locked state (see section 28.7.3, Error Protection).

To make sure that the FCU accepts a command, enter the mode in which the FCU can accept the target command, check the FRDY, ILGLERR, ERSERR, and PRGERR bit values in FSTATR0, and the FCUERR bit values in FSTATR1, and then issue the target FCU command. The CMDLK bit in FSTAT holds a value obtained by logical ORing the ILGLERR, ERSERR, and PRGERR bit values in FSTATR0 and the FCUERR bit values in the FSTATR1. Therefore the FCU's error occurrence state can be checked by reading the CMDLK bit. In table 28.8, the CMDLK bit is used as the bit to indicate the error occurrence state. The FRDY bit of FSTATR0 is 0 during the programming/erase, programming/erase suspension, and blank check processes. While the FRDY bit is 0, the P/E suspend command can be accepted only when the SUSRDY bit in FSTATR0 is 1.

Table 28.8 includes 0 and 1 in single cells of the ERSSPD, PRGSPD, and FRDY bit rows for the sake of simplification. The ERSSPD bits 1 and 0 indicate the erase suspension and programming suspension processes, respectively. The PRGSPD bits 1 and 0 indicate the programming suspension and erase suspension processes, respectively. The FRDY bit value can be either 1 or 0, which is a value held by the bit prior to a transition to the command lock state.

**Table 28.8 FCU Modes/States and Acceptable Commands**

| Item                                            | P/E Normal Mode       |                   |             | Status Read Mode               |                                           |                        |                       |                   |                |             | Lock Bit Read Mode    |                   |             |
|-------------------------------------------------|-----------------------|-------------------|-------------|--------------------------------|-------------------------------------------|------------------------|-----------------------|-------------------|----------------|-------------|-----------------------|-------------------|-------------|
|                                                 | Programming-Suspended | Erasure-Suspended | Other State | Programming/Erasure Processing | Programming/Erasure Suspension Processing | Blank Check Processing | Programming-Suspended | Erasure-Suspended | Command-Locked | Other State | Programming-Suspended | Erasure-Suspended | Other State |
| FRDY bit in FSTATR0                             | 1                     | 1                 | 1           | 0                              | 0                                         | 0                      | 1                     | 1                 | 0/1            | 1           | 1                     | 1                 | 1           |
| SUSRDY bit in FSTATR0                           | 0                     | 0                 | 0           | 1                              | 0                                         | 0                      | 0                     | 0                 | 0              | 0           | 0                     | 0                 | 0           |
| ERSSPD bit in FSTATR0                           | 0                     | 1                 | 0           | 0                              | 0/1                                       | 0                      | 0                     | 1                 | 0              | 0           | 0                     | 1                 | 0           |
| PRGSPD bit in FSTATR0                           | 1                     | 0                 | 0           | 0                              | 0/1                                       | 0                      | 1                     | 0                 | 0              | 0           | 1                     | 0                 | 0           |
| CMDLK bit in FASTAT                             | 0                     | 0                 | 0           | 0                              | 0                                         | 0                      | 0                     | 0                 | 1              | 0           | 0                     | 0                 | 0           |
| Normal mode transition                          | A                     | A                 | A           | ×                              | ×                                         | ×                      | A                     | A                 | ×              | A           | A                     | A                 | A           |
| Status read mode transition                     | A                     | A                 | A           | ×                              | ×                                         | ×                      | A                     | A                 | ×              | A           | A                     | A                 | A           |
| Lock bit read mode transition (lock bit read 1) | A                     | A                 | A           | ×                              | ×                                         | ×                      | A                     | A                 | ×              | A           | A                     | A                 | A           |
| Program                                         | ×                     | *                 | A           | ×                              | ×                                         | ×                      | ×                     | *                 | ×              | A           | ×                     | *                 | A           |
| Block erase                                     | ×                     | ×                 | A           | ×                              | ×                                         | ×                      | ×                     | ×                 | ×              | A           | ×                     | ×                 | A           |
| P/E suspend                                     | ×                     | ×                 | ×           | A                              | ×                                         | ×                      | ×                     | ×                 | ×              | ×           | ×                     | ×                 | ×           |
| P/E resume                                      | A                     | A                 | ×           | ×                              | ×                                         | ×                      | A                     | A                 | ×              | ×           | A                     | A                 | ×           |
| Status register clear                           | A                     | A                 | A           | ×                              | ×                                         | ×                      | A                     | A                 | A              | A           | A                     | A                 | A           |
| Blank check                                     | A                     | A                 | A           | ×                              | ×                                         | ×                      | A                     | A                 | ×              | A           | A                     | A                 | A           |
| Peripheral clock notification                   | ×                     | ×                 | A           | ×                              | ×                                         | ×                      | ×                     | ×                 | ×              | A           | ×                     | ×                 | A           |

×: Not acceptable

### 28.6.3 FCU Command Usage

This section shows how to program and erase the FLD using the program command and block erase command, respectively, and how to check the erasure status of the FLD using the blank check command. For the firmware transfer to the FCU RAM and the other FCU command usage, refer to section 27.6.3, FCU Command Usage.

If the FCU enters the command lock state in the middle of its handling of commands by setting the FCUERR bit in FSTATR1 to 1, the FRDY bit in FSTATR0 retains 0. Since the FCU halts its operation in the command lock state, the FRDY bit is not set to 1 from 0.

If the FRDY bit retains 0 for longer than the programming/erasure time or suspend delay time (see section 33, Electrical Characteristics), an abnormal operation may have occurred. In such case, initialize the FCU by issuing an FCU reset.

If the FRDY bit is set to 1 upon the termination of an FCU command operation, the FCUERR bit is cleared to 0. On the other hand, it can be checked via the ILGLERR, ERSERR, or PRGERR bit whether or not an error has occurred after a command operation terminates.

#### (1) Using the Peripheral Clock Notification Command

The command is used for notification of the peripheral clock frequency. For details, see section 27.6.3, FCU Command Usage, in section 27, Flash Memory (ROM). Proceed by setting the FENTRYD bit in FENTRYR to 1 and specifying the address as an address within the region corresponding to the data flash (FLD).

#### (2) Programming

To program the FLD, use the program command. Write byte H'E8 to an FLD area address in the first cycle of the program command and the number of words (N)\* to be programmed through byte access in the second cycle. Access the P bus in words from the third cycle to cycle N + 2 of the command. In the third cycle, write the programming data to the start address of the target programming area. Here, the start address must be an 8-byte boundary address for 8-byte programming or a 128-byte boundary address for 128-byte programming. After writing words to FLD area addresses N times, write byte H'D0 to an FLD area address in cycle N + 3; the FCU then starts FLD programming. Read the FRDY bit in FSTATR0 to confirm that FLD programming is completed.

If the area accessed in the third cycle to cycle  $N + 2$  includes addresses that do not need to be programmed, write H'FFFF as the programming data for those addresses. To ignore the programming and erasure protection provided by the EEPWE0 and EEPWE1 settings, set the program/erase enable bit for the target block to 1 before starting programming. To ignore the protection provided by the lock bit during programming, set the FPROTCN bit in FPROTR to 1 before starting programming. Figure 28.6 shows the procedure for FLD programming

Note: \*  $N = H'04$  for 8-byte programming or  $N = H'40$  for 128-byte programming.

Notes: \*  $t_{P128}$ : Time required for programming 128-byte data (see section 33, Electrical Characteristics).

$t_{RESW2}$ : Reset pulse width during programming and erasure (see section 33, Electrical Characteristics).

**Figure 28.6 Procedure for FLD Programming**

### (3) Erasure

To erase the ROM, use the block erase command. The FLD can be erased in the same way as ROM erasure (refer to section 27, Flash Memory (ROM)). Note that the FLD has a programming and erasure protection function through a register. To ignore the programming and erasure protection provided by the EEPWE0 setting, set the program/erase enable bit for the target block to 1 before starting erasure.

### (4) Checking of the Erased State

Since reading the FLD erased by the CPU results in undefined values, the blank check command should be used to check the erased state of the FLD. To make the blank check command available for use, set the FRDMD bit in FMODR to 1 to enable the command first, and then specify the size and start address of a target area via the EEPBCCNT register. When the BCSIZE bit of the EEPBCCNT register is set to 1, a check can be performed on the entire erased block (8 Kbytes) specified in the second cycle of the command. When the BCSIZE bit is set to 0, a check can be performed on an 8-byte area starting from the address obtained by summing the start address of the erased area specified in the second cycle of the command and the value held by the EEPBCCNT register. In the first cycle of the command, a value of H'71 is written in byte into an address of the FLD. In the second cycle, once a value of H'D0 is written into a specified address included in the target area, the FCU starts the blank check on the FLD. It can be checked whether or not the check is complete via the FRDY bit in the FSTATR0. After the blank check is complete, it can be checked whether the target area is erased or filled with 0s and/or 1s via the BCST bit of the EEPBCSTAT register.

Figure 28.7 shows the procedure of the FLD blank check.

Notes: \*  $t_{BCK}$ : Time required for blank check (see section 33, Electrical Characteristics).  
 $t_{RESW2}$ : Reset pulse width during programming and erasure (see section 33, Electrical Characteristics).

**Figure 28.7 Procedure of the FLD Blank Check**

## 28.7 Protection

There are three types of FLD programming/erasure protection: hardware, software, and error protection.

### 28.7.1 Hardware Protection

The hardware protection function disables FLD programming and erasure according to the mode pin settings in this LSI.

While the on-chip ROM is disabled, FLD programming, erasing, and reading are disabled. For the operating modes set through the mode pins of this LSI, refer to section 3, MCU Operating Modes.

### 28.7.2 Software Protection

The software protection function disables FLD programming and erasure according to the control register settings. If an attempt is made to issue a programming or erasing command to the FLD against software protection, the FCU detects an error and enters command-locked state.

#### (1) Protection through FENTRYR

When the FENTRYD bit in FENTRYR is 0, the FCU does not accept commands for the FLD, so FLD programming and erasure are disabled. If an attempt is made to issue an FCU command for the FLD while the FENTRYD bit is 0, the FCU detects an illegal command error and enters command-locked state (see section 28.7.3, Error Protection).

#### (2) Protection through EEPWE0

When the DBWE<sub>i</sub> ( $i = 00$  to  $03$ ) bit in EEPWE0 is 0, programming and erasure of block DB<sub>i</sub> in the data MAT is disabled. If an attempt is made to program or erase block DB<sub>i</sub> while the DBWE<sub>i</sub> bit is 0, the FCU detects a program/erase protect error and enters command-locked state (see section 28.7.3, Error Protection).

### 28.7.3 Error Protection

The error protection function detects an illegal FCU command issued, an illegal access, or an FCU malfunction, and disables FCU command acceptance (command-locked state). While the FCU is in command-locked state, the FLD cannot be programmed or erased. To cancel command-locked state, issue a status register clear command while FASTAT is H'10.

While the CMDLKIE bit in FAEINT is 1, a flash interface error (FIFE) interrupt is generated if the FCU enters command-locked state (the CMDLK bit in FASTAT becomes 1). While an FLD-related interrupt enable bit (EEPAEIE, EEPIFEIE, EEPRPEIE, or EEPWPEIE) in FAEINT is 1, an FIFE interrupt is generated if the corresponding status bit (EEPAE, EEPIFE, EEPRPE, or EEPWPE) in FASTAT becomes 1.

Table 28.9 shows the error protection types for the FLD and the status bit values (the ILGLERR, ERSERR, and PRGERR bits in FSTATR0 and the EEPAE, EEPIFE, EEPRPE, and EEPWPE bits in FASTST) after each error detection. For the error protection types used in common by the ROM and FLD (FENTRYR setting error, most of illegal command errors, erasing error, programming error, and FCU error), refer to section 27.9.3, Error Protection. If the FCU enters command-locked state due to a command other than a suspend command issued during programming or erasure processing, the FCU continues programming or erasing the FLD. In this state, the P/E suspend command cannot suspend programming or erasure. If a command is issued in command-locked state, the ILGLERR bit becomes 1 and the other bits retain the values set due to the previous error detection.

**Table 28.9 Error Protection Types (for FLD only)**

| Error                       | Description                                                                                                                        | ILGLERR | ERSERR | PRGERR | EEPAE | EEPIFE | EEPRPE | EEPWE |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------|---------|--------|--------|-------|--------|--------|-------|
| Illegal command error       | The value specified in the second cycle of a program command is neither H'04 nor H'40.                                             | 1       | 0      | 0      | 0     | 0      | 0      | 0     |
|                             | A lock bit program command has been issued to an area in the FLD while the FENTRYD bit of FENTRYR register is set to 1.            | 1       | 0      | 0      | 0     | 0      | 0      | 0     |
| FLD access error            | A read access command has been issued to the FLD area while FENTRYD = 1 in FENTRYR in FLD P/E normal mode.                         | 1       | 0      | 0      | 1     | 0      | 0      | 0     |
|                             | A write access command has been issued to the FLD area while FENTRYD = 0.                                                          | 1       | 0      | 0      | 1     | 0      | 0      | 0     |
|                             | An access command has been issued to the FLD area while the FENTRY0 bit in FENTRYR is 1.                                           | 1       | 0      | 0      | 1     | 0      | 0      | 0     |
| FLD instruction fetch error | An instruction fetch has been made in the FLD area.                                                                                | 1       | 0      | 0      | 0     | 1      | 0      | 0     |
| FLD read protect error      | A read access command has been issued to the FLD area protected against reading through EEPRE0.                                    | 1       | 0      | 0      | 0     | 0      | 1      | 0     |
| FLD program protect error   | A program command or block erase command has been issued to the FLD area protected against programming and erasure through EEPWE0. | 1       | 0      | 0      | 0     | 0      | 0      | 1     |

## 28.8 Usage Notes

### 28.8.1 Protection of Data MAT Immediately after a Reset

As the initial value of EEPRE0 and EEPWE0 is H'0000, data MAT programming, erasure, and reading are disabled immediately after a reset. To read data from the data MAT, set EEPRE0 appropriately before accessing the data MAT. To program or erase the data MAT, set EEPWE0 appropriately before issuing an FCU command for programming or erasure. If an attempt is made to read, program, or erase the data MAT without setting the registers, the FCU detects an error and enters command-locked state.

### 28.8.2 State in which Interrupts are Ignored

In the following modes or period, the NMI or maskable interrupt requests are ignored.

- Boot mode or USB boot mode
- Programmer mode
- The program in the embedded program stored MAT is being executed immediately after the LSI is started in user boot mode

### 28.8.3 Programming-/Erasure-Suspended Area

The data stored in the programming-suspended or erasure-suspended area is undetermined. To avoid malfunction due to undefined read data, ensure that no data is read from the programming-suspended or erasure-suspended area.

### 28.8.4 Compatibility with Programming/Erasing Program of Conventional F-ZTAT SH Microcontrollers

The flash memory programming/erasing program used for conventional F-ZTAT SH microcontrollers does not work with this LSI.

### 28.8.5 Reset during Programming or Erasure

To reset the FCU by setting the FRESET bit in the FRESETR register during programming or erasure, hold the FCU in the reset state for a period of  $t_{\text{RESW2}}$  (see section 33, Electrical Characteristics). Since a high voltage is applied to the FLD during programming and erasure, the FCU has to be held in the reset state long enough to ensure that the voltage applied to the memory unit has dropped. Do not read from the FLD while the FCU is in the reset state.

When a power-on reset is generated by asserting the  $\overline{\text{RES}}$  pin during programming or erasure of the flash memory, hold the reset state for a period of  $t_{\text{RESW2}}$  (see section 33, Electrical Characteristics). In a power-on reset, not only does the voltage applied to the memory unit have to drop, but the power supply for the FLD and its internal circuitry also have to be initialized. Thus, the reset state must be maintained over a longer period than in the case of resetting the FCU.

When executing a power-on reset by asserting the  $\overline{\text{RES}}$  pin or the FCU reset with the FRESET bit set in FRESETR during programming/erasure, all data including a lock bit of a programming/erasure target area are undefined.

While programming or erasure is performed, do not generate an internal reset caused by WDT counter overflow. A reset caused by WDT cannot ensure a sufficient time required for voltage drop for the memory unit, initialization of the power supply for the FLD, or initialization of its internal circuit.

### 28.8.6 Suspension by Programming/Erasure Suspension

When suspending programming/erasure processing with the programming/erasure suspend command, make sure to complete the operations with the resume command.

### 28.8.7 Prohibition of Additional Programming

One area cannot be programmed twice in succession. To program an area that has already been programmed, be sure to erase the area before reprogramming.

### 28.8.8 Program for Reading

Execute program code for reading the FLD from on-chip RAM or on-chip ROM.

### 28.8.9 Items Prohibited during Programming and Erasure

High voltages are applied within the data memory (ROM) during programming and erasure. To prevent destruction of the chip, ensure that the following operations are not performed during programming and erasure.

- Cutting off the power supply
- Transitions to software standby mode
- Read access to the flash memory by the CPU, DMAC or DTC
- Writing a new value to the FRQCR register
- Setting the PCKAR register for a different frequency from that of P $\phi$ .

### 28.8.10 Abnormal Ending of Programming or Erasure

A lock bit may be set to 0 (in the protected state) due to a reset, an FCU reset by the FRESET bit in the FRESETR register, a transition to the command-locked state because an error has been detected, or programming or erasure not being completed normally.

If this is the case, issue a block erase command to erase the lock bit while the FPROTR.FPROTCN bit is set to 1. After that, repeat the programming until it is finished.

### 28.8.11 Handling when Erasure or Programming is Stopped

Checking of areas in which the data have become undefined due to the erasure or programming in progress being stopped (e.g. by input of the reset signal or shutting down the power) to see whether the data have actually been erased or written is not possible. When the data in an area have become undefined, erase the area completely before using it again.

## Section 29 On-Chip RAM

The SH7214 and SH7216 Groups incorporate 128-Kbyte RAM, which is connected to F (Fetch), M (Memory), and I (Internal) buses. This on-chip RAM can be accessed via any of these buses independently.

Figure 29.1 shows RAM block diagrams and figure 29.2 shows RAM and bus connections.

The on-chip RAM is allocated in addresses H'FFF80000 to H'FFF9FFFF (pages 0 to 7), as shown in table 29.1.

### 29.1 Features

- Access

The CPU/FPU, DMAC, and DTC can access on-chip RAM in 8, 16, or 32 bits. Data in the on-chip RAM can be effectively used as program area or stack area data necessary for access at high speed.

Four pages (pages 0 to 3): one cycle in case of writing and reading

Four pages (pages 4 to 7): two cycles in case of writing, three cycles in case of reading

- Ports

Each page in the on-chip RAM has two independent read and write ports. The read port is connected to I, F, and M buses and the write port is connected to I and M buses. The F and M buses are used for accesses from the CPU. The I bus is used for accesses from external address spaces.

- Priority

If the same page is accessed from multiple buses simultaneously, the access is performed according to the bus priority. The bus priority is as follows: I bus (highest), M bus (middle), F bus (lowest).

- Pages

SH72167, SH72147: 128 Kbytes, eight pages (0 to 7 pages)

SH72166, SH72146: 96 Kbytes, six pages (0 to 5 pages)

SH72165, SH72145: 64 Kbytes, four pages (0 to 3 pages)

## 29.2 Register Descriptions

The on-chip RAM has registers shown in table 29.2.

**Table 29.2 Register Configuration**

| <b>Register Name</b>      | <b>Abbreviation</b> | <b>R/W</b> | <b>Initial Value</b> | <b>Address</b> | <b>Access Size</b> |
|---------------------------|---------------------|------------|----------------------|----------------|--------------------|
| System control register 1 | SYSCR1              | R/W        | H'FF                 | H'FFFE0402     | 8                  |
| System control register 2 | SYSCR2              | R/W        | H'FF                 | H'FFFE0404     | 8                  |

### 29.2.1 System Control Register 1 (SYSCR1)

SYSCR1 is an 8-bit readable/writable register that enables or disables access to the on-chip RAM. SYSCR1 is initialized to H'FF by a power-on reset but retains its previous value by a manual reset or in software standby mode. Only byte access is valid.

When an RAME bit is set to 1, the corresponding on-chip RAM area is enabled. When an RAME bit is cleared to 0, the corresponding on-chip RAM area cannot be accessed. In this case, an undefined value is returned when reading data or fetching an instruction from the on-chip RAM, and writing to the on-chip RAM is ignored. The initial value of an RAME bit is 1.

Note that when clearing the RAME bit to 0 to disable the on-chip RAM, be sure to execute an instruction to read from or write to the same arbitrary address in each page before setting the RAME bit. If such an instruction is not executed, the data last written to each page may not be written to the on-chip RAM. Furthermore, an instruction to access the on-chip RAM should not be located immediately after the instruction to write to SYSCR1. If an on-chip RAM access instruction is set, normal access is not guaranteed.

Additionally, note that when setting the RAME bit to 1 to enable the on-chip RAM, be sure to locate an instruction to read SYSCR1 immediately after the instruction to write to SYSCR1. If an on-chip RAM access instruction is set, normal access is not guaranteed.

|                |       |       |       |       |       |       |       |       |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Bit:           | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |

## 29.2.2 System Control Register 2 (SYSCR2)

SYSCR2 is an 8-bit readable/writable register that enables or disables write to the on-chip RAM. SYSCR2 is initialized to H'FF by a power-on reset but retains its previous value by a manual reset or in software standby mode. Only byte access is valid.

When an RAMWE bit is set to 1, the corresponding on-chip RAM area is enabled. When an RAMWE bit is cleared to 0, the corresponding on-chip RAM area cannot be written to. In this case, writing to the on-chip RAM is ignored. The initial value of an RAMWE bit is 1.

Note that when clearing the RAME bit to 0 to disable the on-chip RAM, be sure to execute an instruction to read from or write to the same arbitrary address in each page before setting the RAMWE bit. If such an instruction is not executed, the data last written to each page may not be written to the on-chip RAM. Furthermore, an instruction to access the on-chip RAM should not be located immediately after the instruction to write to SYSCR2. If an on-chip RAM access instruction is set, normal access is not guaranteed.

Additionally, note that when setting the RAME bit to 1 to enable the on-chip RAM, be sure to locate an instruction to read SYSCR2 immediately after the instruction to write to SYSCR2. If an on-chip RAM access instruction is set, normal access is not guaranteed.

## 29.3 Notes on Usage

### 29.3.1 Page Conflict

If the same page is accessed by the different buses simultaneously, a page conflict occurs. Each of those accesses is handled in such priority scheme as: I bus (highest), M bus (middle), F bus (lowest).

In this case, each access is completed normally but this conflict degrades the memory access efficiency. To avoid this conflict, it is recommended to take preventative measures by software. For example, accessing different memory or different pages using different buses can avoid page conflict.

## Section 30 Power-Down Modes

In power-down modes, operation of some of the internal peripheral modules and of the CPU stops. This leads to reduced power consumption. These modes are canceled by a reset or interrupt.

### 30.1 Features

#### 30.1.1 Power-Down Modes

This LSI has the following power-down modes and function:

1. Sleep mode
2. Software standby mode
3. Module standby function

Table 30.1 shows the transition conditions for entering the modes from the program execution state, as well as the CPU and peripheral module states in each mode and the procedures for canceling each mode.

**Table 30.1 States of Power-Down Modes**

| Power-Down Mode         | Transition Conditions                                                | State* |       |              |                                            |                            |                 | Canceling Procedure                                                                                                                          |
|-------------------------|----------------------------------------------------------------------|--------|-------|--------------|--------------------------------------------|----------------------------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
|                         |                                                                      | CPG    | CPU   | CPU Register | On-Chip Memory                             | On-Chip Peripheral Modules | External Memory |                                                                                                                                              |
| Sleep mode              | Execute SLEEP instruction with STBY bit cleared to 0 in STBCR        | Runs   | Halts | Held         | Runs                                       | Runs                       | Auto-refreshing | <ul style="list-style-type: none"> <li>• Interrupt</li> <li>• Manual reset</li> <li>• Power-on reset</li> <li>• DMA address error</li> </ul> |
| Software standby mode   | Execute SLEEP instruction with STBY bit set to 1 in STBCR            | Halts  | Halts | Held         | Halts (contents are held)                  | Halts                      | Self-refreshing | <ul style="list-style-type: none"> <li>• NMI interrupt</li> <li>• IRQ interrupt</li> <li>• Manual reset</li> <li>• Power-on reset</li> </ul> |
| Module standby function | Set the MSTP bits in STBCR2, STBCR3, STBCR4, STBCR5, and STBCR6 to 1 | Runs   | Runs  | Held         | Specified module halts (contents are held) | Specified module halts     | Auto-refreshing | <ul style="list-style-type: none"> <li>• Clear MSTP bit to 0</li> <li>• Power-on reset (only for H-UDI, UBC, and DMAC)</li> </ul>            |

Note: \* The pin state is retained or set to high impedance. For details, see appendix A, Pin States.

### 30.1.2 Reset

A reset is used when the power is turned on or to run the LSI again from the initialized state. There are two types of reset: power-on reset and manual reset. In a power-on reset, all the ongoing processing is halted and any unprocessed events are canceled, and the reset processing starts immediately. On the other hand, a manual reset does not interrupt processing to retain external memory data. Conditions for generating a power-on reset or manual reset are as follows:

#### (1) Power-On Reset

1. A low level is input to the  $\overline{\text{RES}}$  pin.
2. The watchdog timer (WDT) starts counting with the  $\text{WT}/\overline{\text{IT}}$  bit in WTC SR set to 1 and with the RSTS bit in WRCSR set to 0 while the RSRE bit in WRCSR is 1, and the counter overflows.
3. The H-UDI reset is generated (for details on the H-UDI reset, see section 31, User Debugging Interface (H-UDI)).

#### (2) Manual Reset

1. A low level is input to the  $\overline{\text{MRES}}$  pin.
2. The WDT starts counting with the  $\text{WT}/\overline{\text{IT}}$  bit in WTC SR set to 1 and with the RSTS bit in WRCSR set to 1 while the RSRE bit in WRCSR is 1, and the counter overflows.

## 30.2 Input/Output Pins

Table 30.2 lists the pins used for power-down modes.

**Table 30.2 Pin Configuration**

| <b>Name</b>    | <b>Pin Name</b>          | <b>I/O</b> | <b>Function</b>                                                         |
|----------------|--------------------------|------------|-------------------------------------------------------------------------|
| Power-on reset | $\overline{\text{RES}}$  | Input      | Power-on reset processing starts when a low level is input to this pin. |
| Manual reset   | $\overline{\text{MRES}}$ | Input      | Manual reset processing starts when a low level is input to this pin.   |

### 30.3 Register Descriptions

The following registers are used in power-down modes.

**Table 30.3 Register Configuration**

| Register Name              | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------------|--------------|-----|---------------|------------|-------------|
| Standby control register   | STBCR        | R/W | H'00          | H'FFFE0014 | 8           |
| Standby control register 2 | STBCR2       | R/W | H'00          | H'FFFE0018 | 8           |
| Standby control register 3 | STBCR3       | R/W | H'7E          | H'FFFE0408 | 8           |
| Standby control register 4 | STBCR4       | R/W | H'F7          | H'FFFE040C | 8           |
| Standby control register 5 | STBCR5       | R/W | H'FF          | H'FFFE0418 | 8           |
| Standby control register 6 | STBCR6       | R/W | H'DF          | H'FFFE041C | 8           |

#### 30.3.1 Standby Control Register (STBCR)

STBCR is an 8-bit readable/writable register that specifies the state of the power-down mode. This register is initialized to H'00 by a power-on reset but retains its previous value by a manual reset or in software standby mode. Only byte access is possible.

|                |      |   |   |   |   |   |   |   |
|----------------|------|---|---|---|---|---|---|---|
| Bit:           | 7    | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                | STBY | - | - | - | - | - | - | - |
| Initial value: | 0    | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R/W  | R | R | R | R | R | R | R |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                             |
|--------|----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | STBY     | 0             | R/W | Software Standby<br>Specifies transition to software standby mode.<br>0: Executing SLEEP instruction puts chip into sleep mode.<br>1: Executing SLEEP instruction puts chip into software standby mode. |
| 6 to 0 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                        |

### 30.3.2 Standby Control Register 2 (STBCR2)

STBCR2 is an 8-bit readable/writable register that controls the operation of modules in power-down modes. STBCR2 is initialized to H'00 by a power-on reset but retains its previous value by a manual reset or in software standby mode. Only byte access is possible.

|                |            |           |           |   |   |   |           |   |
|----------------|------------|-----------|-----------|---|---|---|-----------|---|
| Bit:           | 7          | 6         | 5         | 4 | 3 | 2 | 1         | 0 |
|                | MSTP<br>10 | MSTP<br>9 | MSTP<br>8 | - | - | - | MSTP<br>4 | - |
| Initial value: | 0          | 0         | 0         | 0 | 0 | 0 | 0         | 0 |
| R/W:           | R/W        | R/W       | R/W       | R | R | R | R/W       | R |

### 30.3.3 Standby Control Register 3 (STBCR3)

STBCR3 is an 8-bit readable/writable register that controls the operation of modules in power-down modes. STBCR3 is initialized to H'7E by a power-on reset but retains its previous value by a manual reset or in software standby mode. Only byte access is possible.

Notes: When using the USB, Follow the notes shown below. Otherwise the clock will not be generated correctly so that USB can be operated improperly.

1. When selecting the on-chip CPG, set the frequency of the input clock to 12MHz.
2. When using the USB, set the frequency of the peripheral clock (P $\phi$ ) to 13 MHz or more.

## 30.4 Operation

### 30.4.1 Sleep Mode

#### (1) Transition to Sleep Mode

Executing the SLEEP instruction when the STBY bit in STBCR is 0 causes a transition from the program execution state to sleep mode. Although the CPU halts immediately after executing the SLEEP instruction, the contents of its internal registers remain unchanged. The on-chip modules continue to run in sleep mode. Clock pulses are output continuously on the CK pin.

#### (2) Canceling Sleep Mode

Sleep mode is canceled by an interrupt (NMI, IRQ, and on-chip peripheral module), DMA address error, or reset (manual reset or power-on reset).

- Canceling with an interrupt  
When an NMI, IRQ, or on-chip peripheral module interrupt occurs, sleep mode is canceled and interrupt exception handling is executed. When the priority level of the generated interrupt is equal to or lower than the interrupt mask level that is set in the status register (SR) of the CPU, or the interrupt by the on-chip peripheral module is disabled on the module side, the interrupt request is not accepted and sleep mode is not canceled.
- Canceling with a DMAC or DTC address error  
When a DMAC or DTC address error occurs, sleep mode is canceled and DMAC or DTC address error exception handling is executed.
- Canceling with a reset  
Sleep mode is canceled by a power-on reset or a manual reset.

### 30.4.2 Software Standby Mode

#### (1) Transition to Software Standby Mode

The LSI switches from a program execution state to software standby mode by executing the SLEEP instruction when the STBY bit in STBCR is 1. In software standby mode, not only the CPU but also the clock and on-chip peripheral modules halt. The clock output from the CK pin also halts.

The contents of the CPU registers and cache remain unchanged. Some registers of on-chip peripheral modules are, however, initialized. Table 30.4 shows the states of peripheral module registers in software standby mode.

The CPU takes one cycle to finish writing to STBCR, and then executes processing for the next instruction. However, it takes one or more cycles to actually write. Therefore, execute a SLEEP instruction after reading STBCR to have the values written to STBCR by the CPU to be definitely reflected in the SLEEP instruction.

**Table 30.4 Register States in Software Standby Mode**

| Module Name                                     | Initialized Registers         | Registers Whose Content is Retained |
|-------------------------------------------------|-------------------------------|-------------------------------------|
| Interrupt controller (INTC)                     | —                             | All registers                       |
| Clock pulse generator (CPG)                     | —                             | All registers                       |
| User break controller (UBC)                     | —                             | All registers                       |
| Bus state controller (BSC)                      | —                             | All registers                       |
| A/D converter (ADC)                             | All registers                 | —                                   |
| I/O port                                        | —                             | All registers                       |
| User debugging interface (H-UDI)                | —                             | All registers                       |
| Serial communication interface with FIFO (SCIF) | —                             | All registers                       |
| Direct memory access controller (DMAC)          | —                             | All registers                       |
| Multi-function timer pulse unit 2 (MTU2)        | —                             | All registers                       |
| Multi-function timer pulse unit 2S (MTU2S)      | —                             | All registers                       |
| Port output enable 2 (POE2)                     | —                             | All registers                       |
| Compare match timer (CMT)                       | —                             | All registers                       |
| I <sup>2</sup> C bus interface 3 (IIC3)         | BC[2:0] bits in ICMR register | Other than BC[2:0] bits in ICMR     |
| Serial communication interface (SCI)            | —                             | All registers                       |
| USB function module (USB)                       | —                             | All registers                       |
| Renesas serial peripheral interface (RSPI)      | —                             | All registers                       |
| Controller area network (RCAN-IF)               | —                             | All registers                       |

The procedure for switching to software standby mode is as follows:

1. Clear the TME bit in the WDT's timer control register (WTCSR) to 0 to stop the WDT.
2. Set the WDT's timer counter (WTCNT) to 0 and the CKS[2:0] bits in WTCSR to appropriate values to secure the specified oscillation settling time.
3. After setting the STBY bit in STBCR to 1, read STBCR. Then, execute a SLEEP instruction.

## (2) Exit from Software Standby Mode

Software standby mode is exited by interrupts (NMI and IRQ) and resets (a manual reset and power-on reset).

- Canceling with an interrupt

When the falling edge or rising edge of the NMI pin (selected by the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) of the interrupt controller (INTC)) or the falling edge or rising edge of an IRQ pin (IRQ7 to IRQ0) (selected by the IRQn sense select bits (IRQn1S and IRQn0S) in interrupt control register 1 (ICR1) of the interrupt controller (INTC)) is detected, clock oscillation is started. This clock is supplied only to the oscillation settling counter (WDT).

When the time, that has been specified in the clock select bits (CKS[2:0]) in the watchdog timer control/status register (WTCSSR) of the WDT before the transition to the software standby mode, is elapsed, the WDT overflow is generated. This overflow starts to supply the clock to the entire LSI because it is used to decide that the clock is settled. Then, this releases the software standby mode and starts the NMI interrupt exception handling (IRQ interrupt exception handling for the IRRQ).

To release the software standby mode by the NMI interrupt or IRQ interrupt, set bits CKS[2:0] so as the WDT overflow period is longer than the oscillation setting time.

The clock output phase of the CK pin may be unstable immediately after detecting an interrupt and until software standby mode is released. When software standby mode is released by the falling edge of the NMI pin, the NMI pin should be high when the CPU enters software standby mode (when the clock pulse stops) and should be low when software standby mode is re-entered (when the clock is initiated after oscillation settling). When software standby mode is released by the rising edge of the NMI pin, the NMI pin should be low when the CPU enters software standby mode (when the clock pulse stops) and should be high when software standby mode is re-entered (when the clock is initiated after oscillation settling). (The same applies to the IRQ pin.)

- Exit from software standby by a reset

When the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin is driven low, this LSI enters the power-on reset and manual reset and software standby mode is exited.

Keep the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin low until the clock oscillation settles.

Internal clock pulses are output continuously on the CK pin.

### 30.4.3 Application Example of Software Standby Mode

Figure 30.1 shows an example for the timing when software standby mode is entered at the falling edge of the NMI signal and released at the rising edge of the NMI signal.

When the NMI pin is changed from high to low while the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) is 0 (falling edge detection), an NMI interrupt is accepted. When the NMIE bit is set to 1 (rising edge selection) in the NMI exception service routine and the SLEEP instruction is executed with the STBY bit in STBCR is 1, the CPU enters the software standby mode. Then, software standby mode is released when the NMI pin is changed from low to high.

**Figure 30.1 NMI Timing in Software Standby Mode (Application Example)**

### 30.4.4 Module Standby Function

#### (1) Transition to Module Standby Function

Setting the standby control register MSTP bits to 1 halts the supply of clocks to the corresponding on-chip peripheral modules. This function can be used to reduce the power consumption in normal mode and sleep mode. Disable a module before placing it in module standby mode. In addition, do not access the module's registers while it is in the module standby state.

#### (2) Canceling Module Standby Function

The module standby function can be canceled by clearing the MSTP bits to 0, or by a power-on reset (only possible for H-UDI, UBC, DMAC, and DTC). When taking a module out of the module standby state by clearing the corresponding MSTP bit to 0, read the MSTP bit to confirm that it has been cleared to 0.

## 30.5 Usage Notes

### 30.5.1 Current Consumption during Oscillation Settling Time

While waiting for clock oscillation to settle, the current consumption is increased.

### 30.5.2 Notes on Writing to Registers

When writing to a register related to power-down modes by the CPU, after the CPU executes the write instruction, it then executes the subsequent instruction without waiting for the actual writing process to the register to finish.

To update the change made by writing to a register while executing the subsequent instruction, perform a dummy read to the same register between the instruction to write to the register and the subsequent instruction.

### 30.5.3 Notes on Canceling Software Standby Mode with an IRQx Interrupt Request

When canceling software standby mode using an IRQx interrupt request, change the IRQ sense select setting of ICRx in a state in which no IRQx interrupt requests are generated and clear the IRQxF flag in IRQRRx to 0 by the automatic clearing function of the IRQx interrupt processing.

If the IRQxF flag in the IRQ interrupt request register x (IRQRRx) is 1, changing the setting of the IRQ sense select bits in the interrupt control register x (ICRx) or clearing the IRQxF flag in IRQRRx to 0 will clear the relevant IRQx interrupt request but will not clear the software standby cancellation request.

## Section 31 User Debugging Interface (H-UDI)

This LSI incorporates a user debugging interface (H-UDI) for boundary scan function and emulator support.

This section mainly describes the boundary scan function. For the dedicated emulator function of the H-UDI, see the user's manual of the applicable emulator.

### 31.1 Features

The user debugging interface (H-UDI) is a serial input/output interface that conforms to IEEE 1149.1 and has boundary scan, reset, and H-UDI interrupt request functions.

When using an emulator, do not use this interface function.

For the method of connecting the emulator, see the emulator manual.

The H-UDI of this LSI provides the TAP controller for the boundary scan function, separately from the one for the other functions of the H-UDI. When the power is turned on, set the input to the ASEMD0 pin to the high level and keep the TRST and RES pins asserted at the same time for a predetermined period of time, then the boundary scan TAP controller will be selected.

To use the reset or interrupt generation function, it is necessary to issue the switch to H-UDI command to the boundary scan TAP controller. The CPU cannot access the boundary scan control circuit.

Figure 31.1 shows a block diagram of the H-UDI.

Figure 31.1 Block Diagram of H-UDI

## 31.2 Input/Output Pins

Table 31.1 lists the pins of the H-UDI.

**Table 31.1 Pin Configuration**

| Pin Name                           | Symbol                     | I/O    | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Serial data output pin             | TDO                        | Output | <p>Data is output from the H-UDI in synchronization with the falling edge of TCK.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ASE mode select input pin          | $\overline{\text{ASEMD0}}$ | Input  | <p>If a low level is input at the <math>\overline{\text{ASEMD0}}</math> pin while the <math>\overline{\text{RES}}</math> pin is asserted, ASE mode is entered; if a high level is input, product chip mode is entered. In ASE mode, the dedicated emulator function can be used. To use the boundary scan function, input a high level to <math>\overline{\text{ASEMD0}}</math>. Do not change the input level to <math>\overline{\text{ASEMD0}}</math> unless the <math>\overline{\text{RES}}</math> pin is asserted.</p> <p>This pin is pulled up within the chip.</p> |

### 31.3 Boundary Scan TAP Controller

The H-UDI of this LSI provides the TAP controller for the boundary scan function (hereafter referred to as the boundary scan TAP controller), separately from the one for the other functions of the H-UDI. When the power is turned on, set the input to  $\overline{\text{ASEMD0}}$  to the high level and keep  $\overline{\text{TRST}}$  and  $\overline{\text{RES}}$  asserted at the same time for a predetermined period of time, then the boundary scan TAP controller will be selected and the boundary scan function will be enabled.

Note however that the following restrictions should be observed for this LSI.

1. The following pins are not subject to the boundary scan function.
  - Clock-related pins (EXTAL, XTAL, USBEXTAL, and USBXTAL)
  - USB-related pins (USD+ and USD-)
  - System-related pin ( $\overline{\text{RES}}$ )
  - H-UDI-related pins ( $\overline{\text{TRST}}$ , TMS, TCK, TDI, TDO, and  $\overline{\text{ASEMD0}}$ )
2. The PBI2 and PBI3 pins are provided with input boundary scan registers, but not with output (open drain output) boundary scan registers.
3. When the boundary scan function is executed, the maximum frequency of TCK is 6.25 MHz. When an H-UDI function is executed, the maximum frequency of TCK is 25 MHz.
4. When the power is turned on, input a low level to  $\overline{\text{TRST}}$  at the same time with  $\overline{\text{RES}}$  for a predetermined period of time and input the clock signal to EXTAL.
5. A transition to EXTEST, CLAMP, or HIGHZ resets the LSI. To make a transition to another mode from one of these, set  $\overline{\text{ASEMD0}}$ , FWE, MD1, and MD0 to the desired operation mode, input a low level to  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  at the same time for a predetermined period of time, and input the clock signal to EXTAL.
6. Even if a transition to HIGHZ is made, the  $\overline{\text{WDTOVF}}$  pin is driven to the high level, but not at high impedance.

Table 31.2 lists the commands that the boundary scan TAP controller supports. If a command longer than 4 bits is issued from the TDI pin, the last 4 bits of the serial data become valid. Operation is not guaranteed if a reserved value defined in the table is input.

Figure 31.2 shows a switchover sequence from the boundary scan TAP controller to the H-UDI.

**Table 31.2 Commands that Boundary Scan TAP Controller Supports**

| Bit 3 | Bit 2 | Bit 1 | Bit 0 | Description            |
|-------|-------|-------|-------|------------------------|
| 0     | 0     | 0     | 0     | EXTEST                 |

Figure 31.2 Switchover Sequence from Boundary Scan TAP Controller to H-UDI

## 31.4 H-UDI TAP Controller

The H-UDI of this LSI provides the TAP controller for the H-UDI functions (hereafter referred to as H-UDI TAP controller), separately from the boundary scan TAP controller.

This H-UDI TAP controller is enabled by issuing the switch to H-UDI command to the boundary scan TAP controller.

Table 31.3 lists the commands that the H-UDI TAP controller supports. If a command longer than 4 bits is issued from the TDI pin, the last 4 bits of the serial data become valid. Operation is not guaranteed if a reserved value defined in the table is input.

**Table 31.3 Commands that H-UDI TAP Controller Supports**

| TI3 | TI2 | TI1 | TI0 | Description            |
|-----|-----|-----|-----|------------------------|
| 0   | 0   | 0   | 0   | Reserved               |
| 0   | 0   | 0   | 1   | Reserved               |
| 0   | 0   | 1   | 0   | Reserved               |

| 1   | 0   | 1   | 1   | H-UDI interrupt        |
| 1   | 1   | 0   | 0   | Reserved               |
| 1   | 1   | 0   | 1   | Reserved               |
| 1   | 1   | 1   | 0   | IDCODE (Initial value) |
| 1   | 1   | 1   | 1   | BYPASS                 |

## 31.5 Register Descriptions

### 1. Registers of Boundary Scan Circuit

The boundary scan circuit has the following registers.

The on-chip CPU cannot access these registers.

- Bypass register (BSBPR)
- Instruction register (BSIR)
- ID register (BSID)
- Boundary scan register (BSBSR)

### 2. Registers of H-UDI Circuit

The H-UDI circuit has the following registers.

- Instruction register (SDIR)
- ID register (SDID)

#### 31.5.1 Bypass Register (BSBPR)

BSBPR of the boundary scan circuit is a 1-bit register. When the BYPASS command is set, BSBPR is connected between the TDI and TDO pins. The initial value is undefined.

#### 31.5.2 Instruction Register (BSIR)

BSIR of the boundary scan circuit is a 4-bit register that stores a command for the boundary scan TAP controller. The commands that this LSI supports are listed in table 31.2. The initial value of this register is IDCODE (4'b0100). SDIR is initialized when  $\overline{\text{TRST}}$  is low or when in the TAP test-logic-reset state, and can be written to by using the pins listed in table 31.1 irrespective of CPU operation. When a command longer than 4 bits is issued from the TDI pin, the last 4 bits of the serial data are stored in this register. Operation is not guaranteed if a reserved value is set in this register.

#### 31.5.3 ID Register (BSID)

BSID of the boundary scan circuit stores the ID code of this LSI (H'08083447). Set the IDCODE command in the boundary scan circuit and set the TAP state to Shift-DR, then this value can be read from the TDO pin.

### 31.5.4 Boundary Scan Register (BSBSR)

BSBSR of the boundary scan circuit is a shift register arranged on a pad and controls external input/output pins.

Using the commands listed in table 31.2, a boundary scan test conforming to the JTAG standard can be performed.

This register cannot be initialized.

**Table 31.4 Boundary Scan Registers**

| No.      | Pin Name                        | Type     |
|----------|---------------------------------|----------|
| From TDI |                                 |          |
| 321      | FWE/ASEBRKAK/ASEBRK             | OUTPUT   |
| 320      | FWE/ASEBRKAK/ASEBRK             | CONTROL  |
| 319      | FWE/ASEBRKAK/ASEBRK             | INPUT    |

| R/W:           | R   | R   | R   | R   | R  | R  | R | R | R | R | R | R | R | R | R | R |

SDIR of the H-UDI circuit is a 16-bit register that stores a command for the H-UDI TAP controller.

This register is allocated to the address of H'FFFE2000. This register can be read by the CPU, but cannot be written by the CPU.

The initial value of this register is IDCODE (16'hEFFF). It is initialized when  $\overline{\text{TRST}}$  is low or when in the TAP test-logic-reset state, and can be written by input from the pins listed in table 31.1 after setting the switch to H-UDI command in the boundary scan TAP controller.

When a command longer than 4 bits is issued from the TDI pin, the last 4 bits of the serial data are stored in this register. Operation is not guaranteed if a reserved value is set in this register.

### 31.5.6 ID Register (SDID)

SDID of the H-UDI circuit stores the ID code of this LSI (H'08083447). Just as in the case of the boundary scan circuit, set the IDCODE command in the H-UDI TAP controller and set the TAP state to Shift-DR, then this value can be read from the TDO pin.

## 31.6 Operation

### 31.6.1 TAP Controller

Figure 31.3 shows the internal states of the TAP controller.

- The transition condition is the TMS value at the rising edge of TCK.
- The TDI value is sampled at the rising edge of TCK.
- The TDO value changes at the falling edge of TCK. The TDO value is at high impedance, except with Shift-DR and Shift-IR states.
- When a low level is input to  $\overline{\text{TRST}}$ , a transition to the test-logic-reset state occurs.

Figure 31.3 Internal States of TAP Controller

### 31.6.2 Reset Configuration

Table 31.5 shows the reset configuration of this chip.

**Table 31.5 Reset Configuration**

| Operation Mode         | $\overline{\text{ASEMD0}}$ | $\overline{\text{RES}}$ | $\overline{\text{TRST}}$ | Chip State                                   |
|------------------------|----------------------------|-------------------------|--------------------------|----------------------------------------------|
| Product chip mode      | 1                          | 0                       | 0                        | Power-on reset and H-UDI reset               |
|                        |                            |                         | 1                        | Power-on reset                               |
|                        |                            | 1                       | 0                        | H-UDI reset only (Normal operation)          |
|                        |                            |                         | 1                        | Normal operation                             |
| ASE mode* <sup>1</sup> | 0                          | 0                       | 0                        | Power-on reset and H-UDI reset* <sup>2</sup> |
|                        |                            |                         | 1                        | Power-on reset                               |
|                        |                            | 1                       | 0                        | H-UDI reset only                             |
|                        |                            |                         | 1                        | Normal operation                             |

Notes: 1. ASE mode is used for emulator connection. In this mode, the boundary scan and H-UDI functions cannot be used.

2. Reset hold is entered if the  $\overline{\text{TRST}}$  pin is driven low while the  $\overline{\text{RES}}$  pin is negated. In this state, the CPU does not start up.

### 31.6.3 H-UDI Reset

An H-UDI reset is executed by setting an H-UDI reset assert command in the H-UDI TAP controller after setting the switch to H-UDI command (see figure 31.4). An H-UDI reset is of the same kind as a power-on reset. An H-UDI reset is released by setting the H-UDI reset negate command.

The required time between the H-UDI reset assert command and H-UDI reset negate command is the same as the time for keeping the  $\overline{\text{RES}}$  pin low to apply a power-on reset.

**Figure 31.4 H-UDI Reset**

### 31.6.4 H-UDI Interrupt

An interrupt is generated when the H-UDI interrupt command is set in the H-UDI TAP controller after the switch to H-UDI command is set. An H-UDI interrupt has a priority level of 15 and vector number of 14, and jumps to an address based on VBR and returns with an RTE instruction.

### 31.6.5 Boundary Scan Operation

This LSI supports the following commands: BYPASS, SAMPLE/PRELOAD, EXTEST, CLAMP, HIGHZ, and IDCODE.

#### (1) BYPASS

The BYPASS command is a mandatory and standard instruction to operate the bypass register. This command reduces the shift path to speed up serial data transfer of the other LSIs on the printed-circuit board. While executing this command, the test circuit has no effect on the system circuits. The code of the BYPASS command is 4'b1111.

#### (2) SAMPLE/PRELOAD

The SAMPLE/PRELOAD command inputs a value into the boundary scan register from the internal circuit of this LSI, and outputs data from or loads data to the scan path. When this command is executed, a value input to the input pin of this LSI is transferred to the internal circuit and output as it is to the outside through the output pin. While executing this command, the test circuit has no effect on the system circuits. The code of the SAMPLE/PRELOAD command is 4'b0001.

In sampling, a snapshot of the value transferred from the input pin to the internal circuit and from the internal circuit of the output pin is captured into the boundary scan register and read out from the scan path. Capturing a snapshot synchronizes with the rising edge of TCK in the Capture-DR state. Capturing does not interfere with the normal operation of this LSI.

In preloading, in advance of the EXTEST command, an initial value is set in the parallel output latch of the boundary scan register from the scan path. Without PRELOAD operation, an undefined value is output from the output pin until the first scan sequence (transfer to the output latch) is completed (the EXTEST command consistently outputs the parallel output latch to the output pin).

### (3) EXTEST

The EXTEST command conducts a test on the external circuits when mounting this LSI on the printed-circuit board. When this command is executed, the output pin outputs the test data (data set by the SAMPLE/PRELOAD command) from the boundary scan register to the printed-circuit board, and the input pin takes the test result from the printed-circuit board to the boundary scan register.

Since the test circuit controls the pins when this command is executed, the on-chip modules including the CPU of this LSI are set in the reset state.

Therefore, to change operation mode from EXTEST to another (mode in which the chip operates normally), set  $\overline{\text{ASEMD0}}$ , FWE, MD1, and MD0 to the desired operating mode, drive  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  low at the same time for a predetermined period of time, and input the clock signal to EXTAL. The code of the EXTEST command is 4'b0000.

### (4) CLAMP

When the CLAMP command is set, the output pin outputs the value in the boundary scan register preset with the SAMPLE/PRELOAD command. Since the test circuit controls the pins when this command is executed, the on-chip modules including the CPU of this LSI are set in the reset state.

Therefore, to change operation mode from CLAMP to another (mode in which the chip operates normally), set  $\overline{\text{ASEMD0}}$ , FWE, MD1, and MD0 to the desired operating mode, drive  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  low at the same time for a predetermined period of time, and input the clock signal to EXTAL. The code of the CLAMP command is 4'b0010.

### (5) HIGHZ

When the HIGHZ command is set, all the output pins for the boundary scan function except the  $\overline{\text{WDOVF}}$  pin are set to the high impedance state.

Since the test circuit controls the pins when this command is executed, the on-chip modules including the CPU of this LSI are set in the reset state.

Therefore, to change operation mode from HIGHZ to another (mode in which the chip operates normally), set  $\overline{\text{ASEMD0}}$ , FWE, MD1, and MD0 to the desired operating mode, drive  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  low at the same time for a predetermined period of time, and input the clock signal to EXTAL. The code of the HIGHZ command is 4'b0011.

## (6) IDCODE

When the IDCODE is set, IDCODE (H'08083447) of this LSI is output from LSB to the TDO pin if the TAP controller is in the Shift-DR state. While executing this command, the test circuit has no effect on the system circuits. The code of the IDCODE command is 4'b0100.

## 31.7 Usage Notes

1. The following pins are not subject to the boundary scan function.
  - Clock-related pins (EXTAL, XTAL, USBEXTAL, and USBXTAL)
  - USB-related pins (USD+ and USD-)
  - System-related pin ( $\overline{\text{RES}}$ )
  - H-UDI-related pins ( $\overline{\text{TRST}}$ , TMS, TCK, TDI, TDO, and  $\overline{\text{ASEMD0}}$ )
2. The PBI2 and PBI3 pins are provided with input boundary scan registers, but not with output (open drain output) boundary scan registers.
3. Even if a transition to HIGHZ is made, the  $\overline{\text{WDTOVF}}$  pin is driven to the high level, but not at high impedance.
4. The maximum frequency of TCK is 25 MHz.
5. When the power is turned on, input a low level to  $\overline{\text{TRST}}$  at the same time with  $\overline{\text{RES}}$  for a predetermined period of time and input the clock signal to EXTAL. Since TCK, TMS, and TDI are pulled up within the LSI, a current constantly flows if there is a difference in the electrical potentials between the input voltage of the pin and power supply voltage when the boundary scan function is not in use. Be careful especially when in the standby state.
6. A transition to EXTEST, CLAMP, or HIGHZ resets the internal modules including the CPU of this LSI. To make a transition to another mode from one of these, set  $\overline{\text{ASEMD0}}$ , FWE, MD1, and MD0 to the desired operation mode, input a low level to  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$  at the same time for a predetermined period of time, and input the clock signal to EXTAL.
7. An H-UDI command, once set, will not be modified as long as another command is not set again. If the same command is to be set continuously, the command must be set after a command (BYPASS, etc.) that does not affect chip operations is once set.
8. The H-UDI is used for emulator connection and therefore the boundary scan and H-UDI functions described in this section cannot be used when an emulator is used.
9. Fix the TMS pin to the high level for 200 ns after negating the signal on the  $\overline{\text{TRST}}$  pin.
10. When the  $\overline{\text{WDTOVF}}$  pin is being held at the high level due to a boundary scan, proceed after negating the signal on the  $\overline{\text{RES}}$  pin.

**Figure 31.5** Peripheral Circuit Example of  $\overline{\text{RES}}$  and  $\overline{\text{TRST}}$

## Section 32 List of Registers

This section gives information on the on-chip I/O registers of this LSI in the following structures.

1. Register Addresses (by functional module, in order of the corresponding section numbers)
  - Registers are described by functional module, in order of the corresponding section numbers.
  - Access to reserved addresses which are not described in this register address list is prohibited.
  - When registers consist of 16 or 32 bits, the addresses of the MSBs are given when big-endian mode is selected.
2. Register Bits
  - Bit configurations of the registers are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
  - Reserved bits are indicated by — in the bit name.
  - No entry in the bit-name column indicates that the whole register is allocated as a counter or for holding data.
3. Register States in Each Operating Mode
  - Register states are described in the same order as the Register Addresses (by functional module, in order of the corresponding section numbers).
  - For the initial state of each bit, refer to the description of the register in the corresponding section.
  - The register states described are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.
4. Notes when Writing to the On-Chip Peripheral Modules

To access an on-chip module register, two or more peripheral module clock (Pf) cycles are required. Care must be taken in system design. When the CPU writes data to the internal peripheral registers, the CPU performs the succeeding instructions without waiting for the completion of writing to registers. For example, a case is described here in which the system is transferring to the software standby mode for power savings. To make this transition, the SLEEP instruction must be performed after setting the STBY bit in the STBCR register to 1. However a dummy read of the STBCR register is required before executing the SLEEP instruction. If a dummy read is omitted, the CPU executes the SLEEP instruction before the STBY bit is set to 1, thus the system enters sleep mode not software standby mode. A dummy read of the STBCR register is indispensable to complete writing to the STBY bit. To reflect the change by internal peripheral registers while performing the succeeding instructions, execute a dummy read of registers to which write instruction is given and then perform the succeeding instructions.

## 32.1 Register Addresses (by Functional Module, in Order of the Corresponding Section Numbers)

| Module Name | Register Name                               | Abbreviation | Number of Bits | Address    | Access Size |
|-------------|---------------------------------------------|--------------|----------------|------------|-------------|
| CPG         | Frequency control register                  | FRQCR        | 16             | H'FFFE0010 | 16          |
|             | MTU2S clock frequency control register      | MCLKCR       | 8              | H'FFFE0410 | 8           |
|             | AD clock frequency control register         | ACLKCR       | 8              | H'FFFE0414 | 8           |
|             | Oscillation stop detection control register | OSCCR        | 8              | H'FFFE001C | 8           |
| INTC        | Interrupt control register 0                | ICR0         | 16             | H'FFFE0800 | 16, 32      |
|             | Interrupt control register 1                | ICR1         | 16             | H'FFFE0802 | 16          |
|             | IRQ interrupt request register              | IRQRR        | 16             | H'FFFE0806 | 16          |
|             | Bank control register                       | IBCR         | 16             | H'FFFE080C | 16, 32      |
|             | Bank number register                        | IBNR         | 16             | H'FFFE080E | 16          |
|             | Interrupt priority register 01              | IPR01        | 16             | H'FFFE0818 | 16, 32      |
|             | Interrupt priority register 02              | IPR02        | 16             | H'FFFE081A | 16          |
|             | Interrupt priority register 05              | IPR05        | 16             | H'FFFE0820 | 16          |
|             | Interrupt priority register 06              | IPR06        | 16             | H'FFFE0C00 | 16, 32      |
|             | Interrupt priority register 07              | IPR07        | 16             | H'FFFE0C02 | 16          |
|             | Interrupt priority register 08              | IPR08        | 16             | H'FFFE0C04 | 16, 32      |
|             | Interrupt priority register 09              | IPR09        | 16             | H'FFFE0C06 | 16          |
|             | Interrupt priority register 10              | IPR10        | 16             | H'FFFE0C08 | 16, 32      |

| H-UDI           | Instruction register                   | SDIR         | 16             | H'FFFE2000 | 16          |

- Notes: 1. The access sizes of the WDT registers are different between the read and write to prevent incorrect writing.
2. Use the access size set by the SPLW bit.

## 32.2 Register Bits

| Module Name | Register Abbreviation | Bit 31/23/15/7 | Bit 30/22/14/6 | Bit 29/21/13/5 | Bit 28/20/12/4 | Bit 27/19/11/3 | Bit 26/18/10/2 | Bit 25/17/9/1 | Bit 24/16/8/0 |

- Notes:
1. When normal space, SRAM with byte selection, or MPX-I/O is the memory type
  2. When burst ROM (clocked asynchronous) is the memory type
  3. When SDRAM is the memory type
  4. When burst ROM (clocked synchronous) is the memory type

### 32.3 Register States in Each Operating Mode

| Module Name | Register  | Power-on Reset            | Manual Reset           | Software Standby | Module Standby | Sleep    |

- Notes:
1. Retains the previous value after an internal power-on reset by means of the WDT.
  2. Bits BN[3:0] are initialized.
  3. Initialized by TRST assertion or in the Test-Logic-Reset state of the TAP controller.
  4. Initialized after an internal manual reset by means of the WDT.
  5. Some bits are not initialized.

## Section 33 Electrical Characteristics

### 33.1 Absolute Maximum Ratings

Table 33.1 lists the absolute maximum ratings.

**Table 33.1 Absolute Maximum Ratings**

| Item                                     | Symbol                                    | Value                   | Unit |
|------------------------------------------|-------------------------------------------|-------------------------|------|
| Power supply voltage (Internal)          | $V_{CCQ}$ , PLL $V_{CC}$ ,<br>Dr $V_{CC}$ | −0.3 to +4.6            | V    |
| Input voltage (except analog input pins) | $V_{in}$                                  | −0.3 to $V_{CCQ} + 0.3$ | V    |
| Analog power supply voltage              | $AV_{CC}$                                 | −0.3 to +7.0            | V    |
| Analog reference voltage                 | AVREF                                     | −0.3 to $AV_{CC} + 0.3$ | V    |
| Analog input voltage                     | $V_{AN}$                                  | −0.3 to $AV_{CC} + 0.3$ | V    |
| Operating temperature                    | Industrial specifications<br>$T_{opr}$    | −40 to +85              | °C   |
| Storage temperature                      | $T_{stg}$                                 | −55 to +125             | °C   |

Caution: Permanent damage to the LSI may result if absolute maximum ratings are exceeded.  
Supply the Dr $V_{CC}$  with the same voltage as the  $V_{CCQ}$ .

## 33.2 DC Characteristics

Tables 33.2 and 33.3 list DC characteristics.

**Table 33.2 DC Characteristics (1) [Common Items]**

Conditions:  $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

| Item                        |                                                | Symbol                                           | Min. | Typ. | Max. | Unit          | Test Conditions                                                                |
|-----------------------------|------------------------------------------------|--------------------------------------------------|------|------|------|---------------|--------------------------------------------------------------------------------|
| Power supply voltage        |                                                | $V_{CCQ}$ ,<br>$PLL V_{CC}$ ,<br>$DrV_{CC}^{*3}$ | 3.0  | 3.3  | 3.6  | V             |                                                                                |
| Analog power supply voltage |                                                | $AV_{CC}$                                        | 4.5  | 5.0  | 5.5  | V             |                                                                                |

| Three-state leakage current | Input/output pins, all output pins (off state) | $I_{sn}$                                         | —    | —    | 1    | $\mu\text{A}$ | $V_{in} = 0.5\text{ to }V_{CCQ} - 0.5\text{ V}$                                |
| Input capacitance           | All pins                                       | $C_{in}$                                         | —    | —    | 20   | pF            |                                                                                |
| Analog power supply current | During A/D conversion                          | $AI_{CC}$                                        | —    | 3    | 4    | mA            | Per 1 module                                                                   |
|                             | Waiting for A/D conversion                     |                                                  | —    | 30   | 50   | mA            | Per 1 module                                                                   |

| Item                           |                            | Symbol | Min. | Typ. | Max. | Unit | Test Conditions |
|--------------------------------|----------------------------|--------|------|------|------|------|-----------------|
| Reference power supply current | During A/D conversion      | Alref  | —    | 1    | 2    | mA   | Per 1 module    |
|                                | Waiting for A/D conversion |        | —    | 0.8  | 1    | mA   | Per 1 module    |

Caution: When the A/D converter is not in use, the  $AV_{CC}$  and  $AV_{SS}$  pins should not be open. Connect the  $AV_{CC}$  to the  $V_{CCQ}$ .

- Notes: 1. Supply current values are when all output and pull-up pins are unloaded.  
 2.  $I_{CC}$ ,  $I_{sleep}$ , and  $I_{stby}$  represent the total currents consumed in the  $V_{CCQ}$  and  $PLL_{V_{CC}}$  systems.  
 3. Be sure to supply the  $DrV_{CC}$  with the same voltage as the  $V_{CCQ}$ .

**Table 33.2 DC Characteristics (2) [Except for I<sup>2</sup>C-Related Pins]**

Conditions:  $V_{CCQ} = PLL_{V_{CC}} = DrV_{CC} = 3.0$  to  $3.6$  V,  $AV_{CC} = AVREF = 4.5$  to  $5.5$  V,  
 $V_{SS} = PLL_{V_{SS}} = DrV_{SS} = AVREF_{V_{SS}} = AV_{SS} = 0$  V,  
 $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

| Item               |                                                                                                        | Symbol   | Min.            | Typ. | Max.            | Unit | Test Conditions             |

Note: \* When the A/D converter is in use,  $AV_{CC}$  must be from 4.5 to 5.5 V. When it is not in use, connect the  $AV_{CC}$  to the  $V_{CC}Q$ .

**Table 33.3 Permissible Output Currents**

Conditions:  $V_{CC}Q = PLLV_{CC} = DrV_{CC} = 3.0$  to  $3.6$  V,  
 $V_{SS} = PLLV_{SS} = DrV_{SS} = AVREFV_{SS} = AV_{SS} = 0$  V,  
 $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

| Item                                      | Symbol           | Min. | Typ. | Max.         | Unit |
|-------------------------------------------|------------------|------|------|--------------|------|
| Permissible output low current (per pin)  | $I_{OL}$         | —    | —    | $2.0^{*1*2}$ | mA   |
| Permissible output low current (total)    | $\Sigma I_{OL}$  | —    | —    | 80           | mA   |
| Permissible output high current (per pin) | $-I_{OH}$        | —    | —    | 2            | mA   |
| Permissible output high current (total)   | $\Sigma -I_{OH}$ | —    | —    | 25           | mA   |

Notes: 1. TIOC3B, TIOC3D, TIOC4A to TIOC4D, TIOC3BS, TIOC3DS, TIOC4AS to TIOC4DS:  $I_{OL}$   
 $= 15\text{mA (Max)}/-I_{OH} = 5\text{mA}$ .

SCL and SDA:  $I_{OL} = 8\text{ mA (Max)}$ .

Of these pins, the number of pins from which current more than 2.0 mA runs evenly should be 3 or less.

2. Pins except USD+, USD-

Caution: To protect the LSI's reliability, do not exceed the output current values in table 33.3.

### 33.3 AC Characteristics

Signals input to this LSI are basically handled as signals in synchronization with a clock. The setup and hold times for input pins must be followed.

**Table 33.4 Maximum Operating Frequency**

Conditions:  $V_{cc}Q = PLLV_{cc} = DrV_{cc} = 3.0$  to  $3.6$  V,  $AV_{cc} = AVREF = 4.5$  to  $5.5$  V,  
 $V_{ss} = PLLV_{ss} = DrV_{ss} = AVREFVSS = AV_{ss} = 0$  V,  
 $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

| Item                |                                        | Symbol | Min. | Typ. | Max. | Unit | Remarks |
|---------------------|----------------------------------------|--------|------|------|------|------|---------|

- Notes: 1.  $\overline{\text{RES}}$ , NMI, and IRQ7 to IRQ0 are asynchronous signals. When these setup times are observed, a change of these signals is detected at the clock rising edge. If the setup times are not observed, detection of a signal change may be delayed until the next rising edge of the clock.
2. In standby mode or when the clock multiplication ratio is changed,  $t_{\text{RESW}} = t_{\text{OSC2}}$  (10 ms). Since the CK width is initialized by the  $\overline{\text{RES}}$  pin,  $t_{\text{cyc}}$  becomes the initial value.
3. In standby mode,  $t_{\text{MRESW}} = t_{\text{OSC2}}$  (10 ms).
4. Input the reset pulse over  $t_{\text{RESW1}}$  so that all conditions are met.

- Notes: 1. The maximum value ( $f_{max}$ ) of B $\phi$  (external bus clock) depends on the number of wait cycles and the system configuration of your board.
2. n represents the number of wait cycles.
3. When access-time requirement is satisfied,  $t_{RDS1}$  need not be satisfied.

Notes: 1.  $t_{\text{poyc}}$  indicates peripheral clock (P $\phi$ ) cycle.

2. Depends on the value of NF2CYC.

3. Indicates the I/O buffer characteristic.

| TDO delay time             | $t_{TDOD}$   | —          | $30^{*1}$ | ns           |              |
|                            |              | —          | $80^{*2}$ | ns           |              |
| Output pins other than TDO | $t_{OTHERD}$ | —          | $80^{*2}$ | ns           |              |

Notes: 1. This value must exceed the cycle time for the peripheral clock ( $P\phi$ ).  
 2. TCK cycle time when the boundary scan function is executed.

**Figure 33.66 TCK Input Timing**

**Figure 33.67 H-UDI Data Transmission Timing**

### 33.3.19 AC Characteristics Measurement Conditions

- I/O signal level:  $V_{IL}$  (Max.)/ $V_{IH}$  (Min.)
- Output signal reference level: High level = 2.0 V, low level = 0.8 V
- Input rise and fall times: 1 ns

- Notes: 1.  $C_L$  is the total value that includes the capacitance of measurement tools. Each pin is set as follows:  
 30 pF: CK  
 30 pF: All pins
2. Test conditions include  $I_{OL} = 1.6$  mA and  $I_{OH} = -200$   $\mu$ A.

**Figure 33.68 Output Load Circuit**

## 33.4 A/D Converter Characteristics

**Table 33.23 A/D Converter Characteristics**

Conditions:  $V_{CCQ} = PLLV_{CC} = DrV_{CC} = 3.0$  to  $3.6$  V,  $AV_{CC} = AVREF = 4.5$  to  $5.5$  V,  
 $V_{SS} = PLLV_{SS} = DrV_{SS} = AVREFVSS = AV_{SS} = 0$  V,  
 $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

| Item                                |                                       | Min. | Typ. | Max.      | Unit          | Test Condition                                                |
|-------------------------------------|---------------------------------------|------|------|-----------|---------------|---------------------------------------------------------------|
| Resolution                          |                                       | —    | 12.0 | —         | bits          |                                                               |

**Notes:** 1. Definition of rewrite/erase cycle:

The rewrite/erase cycle is the number of erasing for each block. When the rewrite/erase cycle is  $n$  times ( $n = 1000$ ), erasing can be performed  $n$  times for each block. For instance, when 256-byte writing is performed 32 times for different addresses in 8-Kbyte block and then the entire block is erased, the rewrite/erase cycle is counted as one. However, writing to the same address for several times as one erasing is not enabled (over writing is prohibited).

2. This indicates the minimum number that guarantees the characteristics after rewriting. (The guaranteed value is in the range from one to the minimum number.)
3. This indicates the characteristic when rewrite is performed within the specification range including the minimum number.

**Figure 33.71 Flash Programming/Erasing Suspend Timing**

### 33.7 FLD Characteristics

**Table 33.26 FLD (Flash Memory for Data Storage) Characteristics**

Conditions:  $V_{CCQ} = PLLV_{CC} = DrV_{CC} = 3.0$  to  $3.6$  V,  $AV_{CC} = AVREF = 4.5$  to  $5.5$  V,  
 $V_{SS} = PLLV_{SS} = DrV_{SS} = AVREFVSS = AV_{SS} = 0$  V,  
 Operating temperature range during programming/erasing:  
 $T_a = -40^{\circ}\text{C}$  to  $+85^{\circ}\text{C}$  (Industrial specifications)

Notes: 1. Definition of rewrite/erase cycle:

The rewrite/erase cycle is the number of erasing for each block. When the rewrite/erase cycle is  $n$  times ( $n = 30000$ ), erasing can be performed  $n$  times for each block. For instance, when 128-byte writing is performed 64 times for different addresses in 8-Kbyte block and then the entire block is erased, the rewrite/erase cycle is counted as one. However, writing to the same address for several times as one erasing is not enabled (over writing is prohibited).

2. This indicates the minimum number that guarantees the characteristics after rewriting. (The guaranteed value is in the range from one to the minimum number.)
3. This indicates the characteristic when rewrite is performed within the specification range including the minimum number.

## 33.8 Usage Notes

### 33.8.1 Notes on Connecting Capacitors

This LSI includes an internal step-down circuit to automatically reduce the internal power supply voltage to an appropriate level. Between this internal stepped-down power supply ( $V_{CL}$  pin) and the  $V_{SS}$  pin, a capacitor for stabilizing the internal voltage needs to be connected. Connection of the external capacitor is shown in figure 33.72. The external capacitor should be located near the pin. Do not apply any power supply voltage to the  $V_{CL}$  pin.

A multilayer ceramic capacitor should be inserted for each pair of power supply pins as a bypass capacitor. The bypass capacitor must be inserted as close to the power supply pins of the LSI as possible. Connect the bypass capacitor and the capacitor for stabilizing the internal voltage with the capacitance from 0.02 to 0.33  $\mu\text{F}$ , after being evaluated in the system. For details on capacitors related to crystal oscillation, see section 4.9, Notes on Board Design.

**Figure 33.72 Connection of Capacitors**

# Appendix

## A. Pin States

Pin initial states differ according to MCU operating modes. Refer to section 22, Pin Function Controller (PFC), for details.

**Table A.1 Pin States**

| Pin Function           |               |                       |         | Pin State          |        |                  |                                         |                  |                        |                           |                   |

## [Legend]

I: Input

O: Output

H: High-level output

L: Low-level output

Z: High-impedance

K: Input pins become high-impedance, and output pins retain their state.

- Notes:
1. Output pins become high-impedance when the HIZ bit in standby control register 3 (STBCR3) is set to 1.
  2. Becomes output when the HIZCNT bit in the common control register (CMNCR) is set to 1.
  3. Becomes output when the HIZMEM bit in the common control register (CMNCR) is set to 1.
  4. Becomes output when the HIZCKIO bit in the common control register (CMNCR) is set to 1.
  5. Becomes high-impedance when the MZIZDH bit in the high-current port control register (HCPCR) is set to 0.
  6. Becomes high-impedance when the MZIZDL bit in the high-current port control register (HCPCR) is set to 0.
  7. Becomes high-impedance when the MZIZEH bit in the high-current port control register (HCPCR) is set to 0.
  8. Becomes high-impedance when the MZIZEL bit in the high-current port control register (HCPCR) is set to 0.
  9. Becomes input during a power-on reset. Pull-up to prevent erroneous operation. Pull-down with a resistance of at least 1 MW as required.
  10. Pulled-up inside the LSI when there is no input.

## B. Product Code Lineup

## Item Page Revision (See Manual for Details)

### Table 1.2 Pin Functions 13 Added

| Classification                                                      | Symbol | I/O    | Name                    | Function                                 |
|---------------------------------------------------------------------|--------|--------|-------------------------|------------------------------------------|
| System control                                                      | WDTOVF | Output | Watchdog timer overflow | Outputs an overflow signal from the WDT. |
| Use a resistor with a value of at least 1 MΩ to pull this pin down. |        |        |                         |                                          |

### Figure 3.1 Address Map 77 Amended and added (1-Mbyte Version)

### Figure 3.2 Address Map 78 Amended and added (768-Kbyte Version)

### Figure 3.3 Address Map 79 Amended and added (512-Kbyte Version)

### 4.7 Oscillation Stop Detection 99 Deleted

In addition, the high-current ports (multiplexed pins to which the TIOC3B, TIOC3D, and TIOC4A to TIOC4D signals in the MTU2, the TIOC3BS, TIOC3DS, and TIOC4AS to TIOC4DS in the MTU2S are assigned) can be placed in high-impedance state regardless of settings of the OSCERS bit and PFC. ~~For details, refer to appendix A, Pin Status.~~

|-------------------------|-----|-------|

The data cycle is the same as that in a normal space access.

The delay cycles the number of which is specified by SW[1:0] are inserted between cycle Ta3 and cycle T1. The delay cycles the number of which is specified by HW[1:0] are added after cycle T2.

380 Amended and added

| No. | Condition                | Description                                                                                                                                                                                                                    |
|-----|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (5) | Read data transfer cycle | One idle cycle is inserted after a read access is completed. This idle cycle is not generated for the first or middle cycles in divided access cycles. This is neither generated when the HW[1:0] bits in CSnWCR are not B'00. |

Note: \* This is the case for consecutive read operations when the data read are stored in separate registers.

|------------------------|-----|-------------------|
| 9.5.11 Bus Arbitration | 385 | Added and amended |
|------------------------|-----|-------------------|

In bus arbitration by this LSI, it normally holds bus mastership but can release this after receiving a bus request from another device.

Bus arbitration by this LSI also supports four on-chip bus masters: the CPU, DMAC, DTC, and EDMAC. The priority order of these bus masters is as follows.

Bus mastership request from an external device (BREQ) > EDMAC > DTC > DMAC > CPU.

| 11.3.26 Timer Cycle Data Register (TCDR)                         | 530  | Added<br><br>TCDR is a 16-bit register used only in complementary PWM mode. Set half the PWM carrier sync value (note that this value should be at least double the value specified in TDDR + 3) as the TCDR register value. This register is constantly compared with the TCNTS counter in complementary PWM mode, and when a match occurs, the TCNTS counter switches direction (decrement to increment).                                                                                                                                                                |
| 11.4.4 Cascaded Operation                                        | 552  | Added<br><br>For simultaneous input capture of TCNT_1 and TCNT_2 during cascaded operation, additional input capture input pins can be specified by the input capture control register (TICCR). Edge detection as the condition for input capture is the detection of edges in the signal produced by taking the logical OR of the signals on the main and additional pins. For details, refer to (4), Cascaded Operation Example (c). For input capture in cascade connection, refer to section 11.7.22, Simultaneous Capture of TCNT_1 and TCNT_2 in Cascade Connection. |
| Figure 11.23 Cascaded Operation Example (c)                      | 555  | Note added                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 11.4.5 PWM Modes                                                 | 557  | Amended<br><br>• PWM mode 2<br><br>PWM output is generated using one TGR as the cycle register and the others as duty registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by the cycle register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty registers are identical, the output value does not change when a compare match occurs.                                                                                                           |
| Figure 11.38 Example of Complementary PWM Mode Setting Procedure | 575  | Amended<br><br>[8] Set the dead time in the dead time register (TDDR), 1/2 the carrier cycle in the timer cycle data register (TCDR) and timer cycle buffer register (TCBR), and 1/2 the carrier cycle plus the dead time in TGRA_3 and TGRC_3. When no dead time generation is selected, set 1 in TDDR and 1/2 the carrier cycle + 1 in TGRA_3 and TGRC_3.                                                                                                                                                                                                                |

Figure 19.19 Sample Flowchart for Master Transmit Mode

1019 Added

19.8.2 Note on Master Receive Mode

1027 Added and amended

In addition, when RCVD is set to 1 around the falling edge of the 8th clock and the receive buffer is full, a stop condition may not be issued.

Use either of the following measures 1 or 2 against the situations above.

1. In master receive mode, read ICDRR before the rising edge of the 8th clock.
2. In master receive mode, set RCVD to 1 so that data is received in byte units.

1087 Amended

BRP: BRP[7:0] (bits 7 to 0 in BCR0)

(3) Bit Configuration Register (BCR0, BCR1)

- Requirements of Bit Configuration Register

21.8 CAN Bus Interface

1123 Added

A bus transceiver IC is necessary to connect this LSI to a CAN bus. A Renesas HA13721 transceiver IC and its compatible products are recommended. The specification for this LSI circuit is a 3-V power-supply voltage, so use a level-shifter IC between its CRx0 pin and the Rxd pin of the HA13721. Figure 21.16 shows a sample connection diagram.

Amended

Notes: 2 The initial values of the USBSEL and USBCLK bits in STBCR6 immediately after a power-on reset are 1 and 0, respectively. Wait for the power-on oscillation settling time indicated in section 33.3.1, Clock Timing, before release from the power-on reset state. This secures the oscillation settling time for the 48-MHz USB clock. After halting the clock to change the values of the USBSEL and USBCLK bits, secure the oscillation settling time when restarting the clock.
