

The revision list summarizes the locations of revisions and additions. Details should always be checked by referring to the relevant text.

# SH7214 Group, SH7216 Group

User's Manual: Hardware

Renesas 32-Bit RISC Microcomputer  
SuperH™ RISC engine family/SH7216 Series

# Notice

1. All information included in this document is current as of the date this document is issued. Such information, however, is subject to change without any prior notice. Before purchasing or using any Renesas Electronics products listed herein, please confirm the latest product information with a Renesas Electronics sales office. Also, please pay regular and careful attention to additional and different information to be disclosed by Renesas Electronics such as that disclosed through our website.
  2. Renesas Electronics does not assume any liability for infringement of patents, copyrights, or other intellectual property rights of third parties by or arising from the use of Renesas Electronics products or technical information described in this document. No license, express, implied or otherwise, is granted hereby under any patents, copyrights or other intellectual property rights of Renesas Electronics or others.
  3. You should not alter, modify, copy, or otherwise misappropriate any Renesas Electronics product, whether in whole or in part.
  4. Descriptions of circuits, software and other related information in this document are provided only to illustrate the operation of semiconductor products and application examples. You are fully responsible for the incorporation of these circuits, software, and information in the design of your equipment. Renesas Electronics assumes no responsibility for any losses incurred by you or third parties arising from the use of these circuits, software, or information.
  5. When exporting the products or technology described in this document, you should comply with the applicable export control laws and regulations and follow the procedures required by such laws and regulations. You should not use Renesas Electronics products or the technology described in this document for any purpose relating to military applications or use by the military, including but not limited to the development of weapons of mass destruction. Renesas Electronics products and technology may not be used for or incorporated into any products or systems whose manufacture, use, or sale is prohibited under any applicable domestic or foreign laws or regulations.
  6. Renesas Electronics has used reasonable care in preparing the information included in this document, but Renesas Electronics does not warrant that such information is error free. Renesas Electronics assumes no liability whatsoever for any damages incurred by you resulting from errors in or omissions from the information included herein.
  7. Renesas Electronics products are classified according to the following three quality grades: "Standard", "High Quality", and "Specific". The recommended applications for each Renesas Electronics product depends on the product's quality grade, as indicated below. You must check the quality grade of each Renesas Electronics product before using it in a particular application. You may not use any Renesas Electronics product for any application categorized as "Specific" without the prior written consent of Renesas Electronics. Further, you may not use any Renesas Electronics product for any application for which it is not intended without the prior written consent of Renesas Electronics. Renesas Electronics shall not be in any way liable for any damages or losses incurred by you or third parties arising from the use of any Renesas Electronics product for an application categorized as "Specific" or for which the product is not intended where you have failed to obtain the prior written consent of Renesas Electronics. The quality grade of each Renesas Electronics product is "Standard" unless otherwise expressly specified in a Renesas Electronics data sheets or data books, etc.  
"Standard": Computers; office equipment; communications equipment; test and measurement equipment; audio and visual equipment; home electronic appliances; machine tools; personal electronic equipment; and industrial robots.  
"High Quality": Transportation equipment (automobiles, trains, ships, etc.); traffic control systems; anti-disaster systems; anti-crime systems; safety equipment; and medical equipment not specifically designed for life support.  
"Specific": Aircraft; aerospace equipment; submersible repeaters; nuclear reactor control systems; medical equipment or systems for life support (e.g. artificial life support devices or systems), surgical implantations, or healthcare intervention (e.g. excision, etc.), and any other applications or purposes that pose a direct threat to human life.
  8. You should use the Renesas Electronics products described in this document within the range specified by Renesas Electronics, especially with respect to the maximum rating, operating supply voltage range, movement power voltage range, heat radiation characteristics, installation and other product characteristics. Renesas Electronics shall have no liability for malfunctions or damages arising out of the use of Renesas Electronics products beyond such specified ranges.
  9. Although Renesas Electronics endeavors to improve the quality and reliability of its products, semiconductor products have specific characteristics such as the occurrence of failure at a certain rate and malfunctions under certain use conditions. Further, Renesas Electronics products are not subject to radiation resistance design. Please be sure to implement safety measures to guard them against the possibility of physical injury, and injury or damage caused by fire in the event of the failure of a Renesas Electronics product, such as safety design for hardware and software including but not limited to redundancy, fire control and malfunction prevention, appropriate treatment for aging degradation or any other appropriate measures. Because the evaluation of microcomputer software alone is very difficult, please evaluate the safety of the final products or system manufactured by you.
  10. Please contact a Renesas Electronics sales office for details as to environmental matters such as the environmental compatibility of each Renesas Electronics product. Please use Renesas Electronics products in compliance with all applicable laws and regulations that regulate the inclusion or use of controlled substances, including without limitation, the EU RoHS Directive. Renesas Electronics assumes no liability for damages or losses occurring as a result of your noncompliance with applicable laws and regulations.
  11. This document may not be reproduced or duplicated, in any form, in whole or in part, without prior written consent of Renesas Electronics.
  12. Please contact a Renesas Electronics sales office if you have any questions regarding the information contained in this document or Renesas Electronics products, or if you have any other inquiries.
- (Note 1) "Renesas Electronics" as used in this document means Renesas Electronics Corporation and also includes its majority-owned subsidiaries.
- (Note 2) "Renesas Electronics product(s)" means any product developed or manufactured by or for Renesas Electronics.

# General Precautions in the Handling of MPU/MCU Products

The following usage notes are applicable to all MPU/MCU products from Renesas. For detailed usage notes on the products covered by this manual, refer to the relevant sections of the manual. If the descriptions under General Precautions in the Handling of MPU/MCU Products and in the body of the manual differ from each other, the description in the body of the manual takes precedence.

## 1. Handling of Unused Pins

Handle unused pins in accord with the directions given under Handling of Unused Pins in the manual.

- The input pins of CMOS products are generally in the high-impedance state. In operation with an unused pin in the open-circuit state, extra electromagnetic noise is induced in the vicinity of LSI, an associated shoot-through current flows internally, and malfunctions occur due to the false recognition of the pin state as an input signal become possible. Unused pins should be handled as described under Handling of Unused Pins in the manual.

## 2. Processing at Power-on

The state of the product is undefined at the moment when power is supplied.

- The states of internal circuits in the LSI are indeterminate and the states of register settings and pins are undefined at the moment when power is supplied.

In a finished product where the reset signal is applied to the external reset pin, the states of pins are not guaranteed from the moment when power is supplied until the reset process is completed.

In a similar way, the states of pins in a product that is reset by an on-chip power-on reset function are not guaranteed from the moment when power is supplied until the power reaches the level at which resetting has been specified.

## 3. Prohibition of Access to Reserved Addresses

Access to reserved addresses is prohibited.

- The reserved addresses are provided for the possible future expansion of functions. Do not access these addresses; the correct operation of LSI is not guaranteed if they are accessed.

## 4. Clock Signals

After applying a reset, only release the reset line after the operating clock signal has become stable. When switching the clock signal during program execution, wait until the target clock signal has stabilized.

- When the clock signal is generated with an external resonator (or from an external oscillator) during a reset, ensure that the reset line is only released after full stabilization of the clock signal. Moreover, when switching to a clock signal produced with an external resonator (or by an external oscillator) while program execution is in progress, wait until the target clock signal is stable.

## 5. Differences between Products

Before changing from one product to another, i.e. to one with a different part number, confirm that the change will not lead to problems.

- The characteristics of MPU/MCU in the same group but having different part numbers may differ because of the differences in internal memory capacity and layout pattern. When changing to products of different part numbers, implement a system-evaluation test for each of the products.

# How to Use This Manual

## 1. Objective and Target Users

This manual was written to explain the hardware functions and electrical characteristics of this LSI to the target users, i.e. those who will be using this LSI in the design of application systems. Target users are expected to understand the fundamentals of electrical circuits, logic circuits, and microcomputers.

This manual is organized in the following items: an overview of the product, descriptions of the CPU, system control functions, and peripheral functions, electrical characteristics of the device, and usage notes.

When designing an application system that includes this LSI, take all points to note into account. Points to note are given in their contexts and at the final part of each section, and in the section giving usage notes.

The list of revisions is a summary of major points of revision or addition for earlier versions. It does not cover all revised items. For details on the revised points, see the actual locations in the manual.

The following documents have been prepared for the SH7214 and SH7216 Groups. Before using any of the documents, please visit our web site to verify that you have the most up-to-date available version of the document.

## 2. Description of Numbers and Symbols

Aspects of the notations for register names, bit names, numbers, and symbolic names in this manual are explained below.

### (1) Overall notation

In descriptions involving the names of bits and bit fields within this manual, the modules and registers to which the bits belong may be clarified by giving the names in the forms "module name". "register name". "bit name" or "register name". "bit name".

### (2) Register notation

The style "register name"\_"instance number" is used in cases where there is more than one instance of the same function or similar functions.

[Example] CMCSR\_0: Indicates the CMCSR register for the compare-match timer of channel 0.

### (3) Number notation

Binary numbers are given as B'nnnn (B' may be omitted if the number is obviously binary), hexadecimal numbers are given as H'nnnn or 0xnnnn, and decimal numbers are given as nnnn.

[Examples] Binary: B'11 or 11

Hexadecimal: H'EFA0 or 0xEFA0

Decimal: 1234

### (4) Notation for active-low

An overbar on the name indicates that a signal or pin is active-low.

[Example]  $\overline{\text{WDTOVF}}$

Note: The bit names and sentences in the above figure are examples and have nothing to do with the contents of this manual.

### 3. Description of Registers

Each register description includes a bit chart, illustrating the arrangement of bits, and a table of bits, describing the meanings of the bit settings. The standard format and notation for bit charts and tables are described below.

[Bit Chart]

|                |     |     |       |       |       |    |   |     |     |     |     |     |       |       |       |     |
|----------------|-----|-----|-------|-------|-------|----|---|-----|-----|-----|-----|-----|-------|-------|-------|-----|
| Bit:           | 15  | 14  | 13    | 12    | 11    | 10 | 9 | 8   | 7   | 6   | 5   | 4   | 3     | 2     | 1     | 0   |
|                | —   | —   | ASID2 | ASID1 | ASID0 | —  | — | —   | —   | —   | —   | Q   | ACMP2 | ACMP1 | ACMP0 | IFE |
| Initial value: | 0   | 0   | 0     | 0     | 0     | 0  | 1 | 0   | 0   | 0   | 0   | 0   | 0     | 0     | 0     | 0   |
| R/W:           | R/W | R/W | R/W   | R/W   | R/W   | R  | R | R/W | R/W | R/W | R/W | R/W | R/W   | R/W   | R/W   | R/W |

[Table of Bits]

| Bit      | Bit Name       | Initial Value | R/W | Description                                                          |
|----------|----------------|---------------|-----|----------------------------------------------------------------------|
| 15       | —              | 0             | R   | Reserved                                                             |
| 14       | —              | 0             | R   | These bits are always read as 0.                                     |
| 13 to 11 | ASID2 to ASID0 | All 0         | R/W | Address Identifier<br>These bits enable or disable the pin function. |
| 10       | —              | 0             | R   | Reserved<br>This bit is always read as 0.                            |
| 9        | —              | 1             | R   | Reserved<br>This bit is always read as 1.                            |
| 8 to 0   | —              | 0             | —   | —                                                                    |

Note: The bit names and sentences in the above figure are examples, and have nothing to do with the contents of this manual.

- (1) Bit  
Indicates the bit number or numbers.  
In the case of a 32-bit register, the bits are arranged in order from 31 to 0. In the case of a 16-bit register, the bits are arranged in order from 15 to 0.
- (2) Bit name  
Indicates the name of the bit or bit field.  
When the number of bits has to be clearly indicated in the field, appropriate notation is included (e.g., ASID[3:0]).  
A reserved bit is indicated by "—".  
Certain kinds of bits, such as those of timer counters, are not assigned bit names. In such cases, the entry under Bit Name is blank.
- (3) Initial value  
Indicates the value of each bit immediately after a power-on reset, i.e., the initial value.  
0: The initial value is 0  
1: The initial value is 1  
—: The initial value is undefined
- (4) R/W  
For each bit and bit field, this entry indicates whether the bit or field is readable or writable, or both writing to and reading from the bit or field are impossible.  
The notation is as follows:  
R/W: The bit or field is readable and writable.  
R/(W): The bit or field is readable and writable.  
However, writing is only performed to flag clearing.  
R: The bit or field is readable.  
"R" is indicated for all reserved bits. When writing to the register, write the value under Initial Value in the bit chart to reserved bits or fields.  
W: The bit or field is writable.
- (5) Description  
Describes the function of the bit or field and specifies the values for writing.

#### 4. Description of Abbreviations

The abbreviations used in this manual are listed below.

- Abbreviations specific to this product

| Abbreviation | Description                    |
|--------------|--------------------------------|
| BSC          | Bus controller                 |
| CPG          | Clock pulse generator          |
| DTC          | Data transfer controller       |
| INTC         | Interrupt controller           |
| SCI          | Serial communication interface |
| WDT          | Watchdog timer                 |

- Abbreviations other than those listed above

| Abbreviation | Description                                   |
|--------------|-----------------------------------------------|
| ACIA         | Asynchronous communications interface adapter |
| bps          | Bits per second                               |
| CRC          | Cyclic redundancy check                       |
| DMA          | Direct memory access                          |
| DMAC         | Direct memory access controller               |
| GSM          | Global System for Mobile Communications       |
| Hi-Z         | High impedance                                |
| IEBus        | Inter Equipment Bus                           |
| I/O          | Input/output                                  |
| IrDA         | Infrared Data Association                     |
| LSB          | Least significant bit                         |
| MSB          | Most significant bit                          |
| NC           | No connection                                 |
| PLL          | Phase-locked loop                             |
| PWM          | Pulse width modulation                        |
| SFR          | Special function register                     |
| SIM          | Subscriber Identity Module                    |
| UART         | Universal asynchronous receiver/transmitter   |
| VCO          | Voltage-controlled oscillator                 |

All trademarks and registered trademarks are the property of their respective owners.

| Section 3 MCU Operating Modes .....                                                                                               | 75  |
| 3.1 Selection of Operating Modes .....                                                                                            | 75  |
| 3.2 Input/Output Pins .....                                                                                                       | 76  |
| 3.3 Operating Modes .....                                                                                                         | 76  |
| 3.3.1 Mode 0 (MCU Extension Mode 0) .....                                                                                         | 76  |
| 3.3.2 Mode 1 (MCU Extension Mode 1) .....                                                                                         | 76  |
| 3.3.3 Mode 2 (MCU Extension Mode 2) .....                                                                                         | 76  |
| 3.3.4 Mode 3 (Single Chip Mode) .....                                                                                             | 76  |
| 3.4 Address Map .....                                                                                                             | 77  |
| 3.5 Initial State in This LSI .....                                                                                               | 80  |
| 3.6 Note on Changing Operating Mode .....                                                                                         | 80  |
| Section 4 Clock Pulse Generator (CPG) .....                                                                                       | 81  |
| 4.1 Features .....                                                                                                                | 81  |
| 4.2 Input/Output Pins .....                                                                                                       | 85  |
| 4.3 Clock Operating Modes .....                                                                                                   | 86  |
| 4.4 Register Descriptions .....                                                                                                   | 90  |
| 4.4.1 Frequency Control Register (FRQCR) .....                                                                                    | 90  |
| 4.4.2 MTU2S Clock Frequency Control Register (MCLKCR) .....                                                                       | 93  |
| 4.4.3 AD Clock Frequency Control Register (ACLKCR) .....                                                                          | 94  |
| 4.4.4 Oscillation Stop Detection Control Register (OSCCR) .....                                                                   | 95  |
| 4.5 Changing the Frequency .....                                                                                                  | 96  |
| 4.6 Oscillator .....                                                                                                              | 97  |
| 4.6.1 Connecting Crystal Resonator .....                                                                                          | 97  |
| 4.6.2 External Clock Input Method .....                                                                                           | 98  |
| 4.7 Oscillation Stop Detection .....                                                                                              | 99  |
| 4.8 USB Operating Clock (48 MHz) .....                                                                                            | 100 |
| 4.8.1 Connecting a Ceramic Resonator .....                                                                                        | 100 |
| 4.8.2 Input of an External 48-MHz Clock Signal .....                                                                              | 101 |
| 4.8.3 Handling of pins when a Ceramic Resonator is not Connected<br>(the Internal CPG is Selected or the USB is Not in Use) ..... | 102 |
| 4.9 Notes on Board Design .....                                                                                                   | 103 |
| 4.9.1 Note on Using an External Crystal Resonator .....                                                                           | 103 |
| Section 5 Exception Handling .....                                                                                                | 105 |
| 5.1 Overview .....                                                                                                                | 105 |
| 5.1.1 Types of Exception Handling and Priority .....                                                                              | 105 |
| 5.1.2 Exception Handling Operations .....                                                                                         | 107 |
| 5.1.3 Exception Handling Vector Table .....                                                                                       | 109 |
| 5.2 Resets .....                                                                                                                  | 111 |
| 5.2.1 Types of Reset .....                                                                                                        | 111 |

|                                             |                                                                                         |     |
|---------------------------------------------|-----------------------------------------------------------------------------------------|-----|
| 5.2.2                                       | Power-On Reset .....                                                                    | 112 |
| 5.2.3                                       | Manual Reset .....                                                                      | 113 |
| 5.3                                         | Address Errors .....                                                                    | 115 |
| 5.3.1                                       | Address Error Sources .....                                                             | 115 |
| 5.3.2                                       | Address Error Exception Handling .....                                                  | 116 |
| 5.4                                         | Register Bank Errors.....                                                               | 117 |
| 5.4.1                                       | Register Bank Error Sources.....                                                        | 117 |
| 5.4.2                                       | Register Bank Error Exception Handling .....                                            | 117 |
| 5.5                                         | Interrupts.....                                                                         | 118 |
| 5.5.1                                       | Interrupt Sources.....                                                                  | 118 |
| 5.5.2                                       | Interrupt Priority Level .....                                                          | 119 |
| 5.5.3                                       | Interrupt Exception Handling .....                                                      | 120 |
| 5.6                                         | Exceptions Triggered by Instructions .....                                              | 121 |
| 5.6.1                                       | Types of Exceptions Triggered by Instructions .....                                     | 121 |
| 5.6.2                                       | Trap Instructions .....                                                                 | 122 |
| 5.6.3                                       | Slot Illegal Instructions .....                                                         | 122 |
| 5.6.4                                       | General Illegal Instructions.....                                                       | 123 |
| 5.6.5                                       | Integer Division Instructions.....                                                      | 123 |
| 5.6.6                                       | Floating Point Operation Instruction.....                                               | 124 |
| 5.7                                         | When Exception Sources Are Not Accepted .....                                           | 125 |
| 5.8                                         | Stack Status after Exception Handling Ends.....                                         | 126 |
| 5.9                                         | Usage Notes .....                                                                       | 128 |
| 5.9.1                                       | Value of Stack Pointer (SP) .....                                                       | 128 |
| 5.9.2                                       | Value of Vector Base Register (VBR).....                                                | 128 |
| 5.9.3                                       | Address Errors Caused by Stacking of Address Error Exception Handling .....             | 128 |
| 5.9.4                                       | Note When Changing Interrupt Mask Level (IMASK) of<br>Status Register (SR) in CPU ..... | 128 |
| Section 6 Interrupt Controller (INTC) ..... |                                                                                         | 129 |
| 6.1                                         | Features.....                                                                           | 129 |
| 6.2                                         | Input/Output Pins .....                                                                 | 131 |
| 6.3                                         | Register Descriptions .....                                                             | 132 |
| 6.3.1                                       | Interrupt Priority Registers 01, 02, 05 to 19 (IPR01, IPR02, IPR05 to IPR19) .....      | 133 |
| 6.3.2                                       | Interrupt Control Register 0 (ICR0).....                                                | 135 |
| 6.3.3                                       | Interrupt Control Register 1 (ICR1).....                                                | 136 |
| 6.3.4                                       | IRQ Interrupt Request Register (IRQRR).....                                             | 137 |

| 11.3.1 Timer Control Register (TCR).....                                                                 | 462 |
| 11.3.2 Timer Mode Register (TMDR).....                                                                   | 466 |
| 11.3.3 Timer I/O Control Register (TIOR).....                                                            | 469 |
| 11.3.4 Timer Compare Match Clear Register (TCNTCMPCLR).....                                              | 488 |
| 11.3.5 Timer Interrupt Enable Register (TIER).....                                                       | 489 |
| 11.3.6 Timer Status Register (TSR).....                                                                  | 494 |
| 11.3.7 Timer Buffer Operation Transfer Mode Register (TBTM).....                                         | 501 |
| 11.3.8 Timer Input Capture Control Register (TICCR).....                                                 | 503 |
| 11.3.9 Timer Synchronous Clear Register S (TSYCRS).....                                                  | 504 |
| 11.3.10 Timer A/D Converter Start Request Control Register (TADCR).....                                  | 506 |
| 11.3.11 Timer A/D Converter Start Request Cycle Set Registers<br>(TADCORA_4 and TADCORB_4).....          | 509 |
| 11.3.12 Timer A/D Converter Start Request Cycle Set Buffer Registers<br>(TADCOBRA_4 and TADCOBRB_4)..... | 509 |
| 11.3.13 Timer Counter (TCNT).....                                                                        | 510 |
| 11.3.14 Timer General Register (TGR).....                                                                | 510 |
| 11.3.15 Timer Start Register (TSTR).....                                                                 | 511 |
| 11.3.16 Timer Synchronous Register (TSYR).....                                                           | 513 |
| 11.3.17 Timer Counter Synchronous Start Register (TCSYSTR).....                                          | 515 |
| 11.3.18 Timer Read/Write Enable Register (TRWER).....                                                    | 518 |
| 11.3.19 Timer Output Master Enable Register (TOER).....                                                  | 519 |
| 11.3.20 Timer Output Control Register 1 (TOCR1).....                                                     | 520 |
| 11.3.21 Timer Output Control Register 2 (TOCR2).....                                                     | 523 |
| 11.3.22 Timer Output Level Buffer Register (TOLBR).....                                                  | 526 |
| 11.3.23 Timer Gate Control Register (TGCR).....                                                          | 527 |
| 11.3.24 Timer Subcounter (TCNTS).....                                                                    | 529 |
| 11.3.25 Timer Dead Time Data Register (TDDR).....                                                        | 530 |
| 11.3.26 Timer Cycle Data Register (TCDR).....                                                            | 530 |
| 11.3.27 Timer Cycle Buffer Register (TCBR).....                                                          | 531 |
| 11.3.28 Timer Interrupt Skipping Set Register (TITCR).....                                               | 531 |
| 11.3.29 Timer Interrupt Skipping Counter (TITCNT).....                                                   | 533 |
| 11.3.30 Timer Buffer Transfer Set Register (TBTER).....                                                  | 534 |
| 11.3.31 Timer Dead Time Enable Register (TDER).....                                                      | 536 |
| 11.3.32 Timer Waveform Control Register (TWCR).....                                                      | 537 |
| 11.3.33 Bus Master Interface.....                                                                        | 539 |
| 11.4 Operation.....                                                                                      | 540 |
| 11.4.1 Basic Functions.....                                                                              | 540 |
| 11.4.2 Synchronous Operation.....                                                                        | 546 |

|         |                                                                                                   |     |
|---------|---------------------------------------------------------------------------------------------------|-----|
| 11.4.3  | Buffer Operation .....                                                                            | 548 |
| 11.4.4  | Cascaded Operation .....                                                                          | 552 |
| 11.4.5  | PWM Modes .....                                                                                   | 557 |
| 11.4.6  | Phase Counting Mode .....                                                                         | 562 |
| 11.4.7  | Reset-Synchronized PWM Mode.....                                                                  | 569 |
| 11.4.8  | Complementary PWM Mode.....                                                                       | 572 |
| 11.4.9  | A/D Converter Start Request Delaying Function.....                                                | 614 |
| 11.4.10 | MTU2-MTU2S Synchronous Operation.....                                                             | 619 |
| 11.4.11 | External Pulse Width Measurement.....                                                             | 625 |
| 11.4.12 | Dead Time Compensation.....                                                                       | 626 |
| 11.4.13 | TCNT Capture at Crest and/or Trough in Complementary PWM Operation ...                            | 629 |
| 11.5    | Interrupt Sources .....                                                                           | 630 |
| 11.5.1  | Interrupt Sources and Priorities.....                                                             | 630 |
| 11.5.2  | DMAC and DTC Activation .....                                                                     | 632 |
| 11.5.3  | A/D Converter Activation.....                                                                     | 633 |
| 11.6    | Operation Timing.....                                                                             | 635 |
| 11.6.1  | Input/Output Timing .....                                                                         | 635 |
| 11.6.2  | Interrupt Signal Timing.....                                                                      | 642 |
| 11.7    | Usage Notes .....                                                                                 | 648 |
| 11.7.1  | Module Standby Mode Setting .....                                                                 | 648 |
| 11.7.2  | Input Clock Restrictions .....                                                                    | 648 |
| 11.7.3  | Caution on Period Setting .....                                                                   | 649 |
| 11.7.4  | Contention between TCNT Write and Clear Operations .....                                          | 649 |
| 11.7.5  | Contention between TCNT Write and Increment Operations.....                                       | 650 |
| 11.7.6  | Contention between TGR Write and Compare Match .....                                              | 651 |
| 11.7.7  | Contention between Buffer Register Write and Compare Match .....                                  | 652 |
| 11.7.8  | Contention between Buffer Register Write and TCNT Clear .....                                     | 653 |
| 11.7.9  | Contention between TGR Read and Input Capture.....                                                | 654 |
| 11.7.10 | Contention between TGR Write and Input Capture.....                                               | 655 |
| 11.7.11 | Contention between Buffer Register Write and Input Capture .....                                  | 656 |
| 11.7.12 | TCNT2 Write and Overflow/Underflow Contention in Cascade Connection ..                            | 656 |
| 11.7.13 | Counter Value during Complementary PWM Mode Stop .....                                            | 658 |
| 11.7.14 | Buffer Operation Setting in Complementary PWM Mode .....                                          | 658 |
| 11.7.15 | Reset Sync PWM Mode Buffer Operation and Compare Match Flag .....                                 | 659 |
| 11.7.16 | Overflow Flags in Reset Synchronous PWM Mode .....                                                | 660 |
| 11.7.17 | Contention between Overflow/Underflow and Counter Clearing.....                                   | 661 |
| 11.7.18 | Contention between TCNT Write and Overflow/Underflow .....                                        | 662 |
| 11.7.19 | Cautions on Transition from Normal Operation or PWM Mode 1 to<br>Reset-Synchronized PWM Mode..... | 662 |
| 11.7.20 | Output Level in Complementary PWM Mode and Reset-Synchronized<br>PWM Mode .....                   | 663 |
| 11.7.21 | Interrupts in Module Standby Mode .....                                                           | 663 |

# Section 1 Overview

## 1.1 Features

This LSI is a single-chip RISC microprocessor that integrates a Renesas original RISC CPU core with peripheral functions required for system configuration.

The CPU in this LSI has a RISC-type (Reduced Instruction Set Computer) instruction set and uses a superscalar architecture and a Harvard architecture, which greatly improves instruction execution speed. In addition, the 32-bit internal-bus architecture enhances data processing power. With this CPU, it has become possible to assemble low-cost, high-performance, and high-functioning systems, even for applications that were previously impossible with microprocessors, such as realtime control, which demands high speeds. This LSI also includes the floating-point unit (FPU).

In addition, this LSI includes on-chip peripheral functions necessary for system configuration, such as a large-capacity ROM, a ROM cache, a RAM, a direct memory access controller (DMAC), a data transfer controller (DTC), multi-function timer pulse units 2 (MTU2 and MTU2S), a serial communication interface with FIFO (SCIF), a serial communication interface (SCI), a Renesas serial peripheral interface (RSPI), an A/D converter, an interrupt controller (INTC), I/O ports, I<sup>2</sup>C bus interface 3 (IIC3), a universal serial bus (USB), a controller area network (RCAN-ET), an Ethernet controller (Ether-C), and data flash (FLD).

This LSI also provides an external memory access support function to enable direct connection to various memory devices or peripheral LSIs.

These on-chip functions significantly reduce costs of designing and manufacturing application systems.

The features of this LSI are listed in table 1.1.

Figure 1.3 Pin Assignment (2)

## 1.4 Pin Functions

Table 1.2 lists functions of each pin.

**Table 1.2 Pin Functions**

| Classification | Symbol       | I/O    | Name                            | Function                                                                                                                                                                                                                                                                    |
|----------------|--------------|--------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power supply   | $V_{CL}$     | Input  | Internal step-down power supply | External capacitance pins for internal step-down power supply. All the $V_{CL}$ pins must be connected to the $V_{SS}$ pins via a 0.1- $\mu$ F capacitor (should be placed close to the pins). The system power supply must not be directly connected to the $V_{CL}$ pins. |
|                | $V_{SS}$     | Input  | Ground                          | Ground pins. All the $V_{SS}$ pins must be connected to the system power supply (0 V). This LSI does not operate correctly if there is a pin left open.                                                                                                                     |
|                | $V_{CCQ}$    | Input  | Power supply                    | Power supply pins. All the $V_{CCQ}$ pins must be connected to the system power supply. This LSI does not operate if there is a pin left open.                                                                                                                              |
|                | $PLL V_{CC}$ | Input  | PLL power supply                | Power supply for the on-chip PLL oscillator. Apply the same electric potential as that on the $V_{CCQ}$ pin.                                                                                                                                                                |
|                | $PLL V_{SS}$ | Input  | Ground for PLL                  | Ground pin for the on-chip PLL oscillator.                                                                                                                                                                                                                                  |
| Clock          | EXTAL        | Input  | External clock                  | Connected to a crystal resonator. An external clock signal may also be input to the EXTAL pin.                                                                                                                                                                              |
|                | XTAL         | Output | Crystal                         | Connected to a crystal resonator.                                                                                                                                                                                                                                           |
|                | USBEXTAL     | Input  | Crystal for USB                 | Connected to a resonator for the USB.                                                                                                                                                                                                                                       |
|                | USBXTAL      | Output | Crystal for USB                 | Connected to a resonator for the USB.                                                                                                                                                                                                                                       |
|                | CK           | Output | System clock                    | Supplies the system clock to external devices.                                                                                                                                                                                                                              |

| Classification         | Symbol                     | I/O    | Name                               | Function                                                                                                                                                                                                               |
|------------------------|----------------------------|--------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operating mode control | MD1, MD0                   | Input  | Mode set                           | Sets the operating mode. Do not change the signal levels on these pins during operation.                                                                                                                               |
|                        | $\overline{\text{ASEMD0}}$ | Input  | Debugging mode                     | Enables the E10A-USB emulator functions.<br><br>Input a high level to operate the LSI in normal mode (not in debugging mode). To operate it in debugging mode, apply a low level to this pin on the user system board. |
|                        | FWE                        | Input  | Flash memory write enable          | Pin for flash memory. Flash memory can be protected against writing or erasure through this pin.                                                                                                                       |
| System control         | $\overline{\text{RES}}$    | Input  | Power-on reset                     | This LSI enters the power-on reset state when this signal goes low.                                                                                                                                                    |
|                        | $\overline{\text{MRES}}$   | Input  | Manual reset                       | This LSI enters the manual reset state when this signal goes low.                                                                                                                                                      |
|                        | $\overline{\text{WDTOVF}}$ | Output | Watchdog timer overflow            | Outputs an overflow signal from the WDT.<br><br>Use a resistor with a value of at least 1 M $\Omega$ to pull this pin down.                                                                                            |
|                        | $\overline{\text{BREQ}}$   | Input  | Bus-mastership request             | A low level is input to this pin when an external device requests the release of the bus mastership.                                                                                                                   |
|                        | $\overline{\text{BACK}}$   | Output | Bus-mastership request acknowledge | Indicates that the bus mastership has been released to an external device. Reception of the BACK signal informs the device which has output the $\overline{\text{BREQ}}$ signal that it has acquired the bus.          |

| Classification | Symbol       | I/O    | Name                      | Function                                                                                                                                                                                            |
|----------------|--------------|--------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interrupts     | NMI          | Input  | Non-maskable interrupt    | Non-maskable interrupt request pin. Fix it high when not in use.                                                                                                                                    |
|                | IRQ7 to IRQ0 | Input  | Interrupt requests 7 to 0 | Maskable interrupt request pins. Level-input or edge-input detection can be selected. When the edge-input detection is selected, the rising edge, falling edge, or both edges can also be selected. |
|                | IRQOUT       | Output | Interrupt request output  | Indicates that an interrupt has occurred, enabling external devices to be informed of an interrupt occurrence even while the bus mastership is released.                                            |
| Address bus    | A25 to A0    | Output | Address bus               | Outputs addresses.                                                                                                                                                                                  |
| Data bus       | D31 to D0    | I/O    | Data bus                  | Bidirectional data bus.                                                                                                                                                                             |
| Bus control    | CS7 to CS0   | Output | Chip select 7 to 0        | Chip-select signals for external memory or devices.                                                                                                                                                 |
|                | RD           | Output | Read                      | Indicates that data is read from an external device.                                                                                                                                                |
|                | RD/WR        | Output | Read/write                | Read/write signal.                                                                                                                                                                                  |
|                | BS           | Output | Bus start                 | Bus-cycle start signal.                                                                                                                                                                             |
|                | AH           | Output | Address hold              | Address hold timing signal for the device that uses the address/data-multiplexed bus.                                                                                                               |
|                | WAIT         | Input  | Wait                      | Input signal for inserting a wait cycle into the bus cycles during access to the external space.                                                                                                    |
|                | FRAME        | Output | Frame signal              | In burst MPX-I/O interface mode, negated before the last bus cycle to indicate that the next bus cycle is the last access                                                                           |
|                | WRHH         | Output | Write to HH byte          | Indicates a write access to bits 31 to 24 of data of external memory or device.                                                                                                                     |
|                | WRHL         | Output | Write to HL byte          | Indicates a write access to bits 23 to 16 of data of external memory or device.                                                                                                                     |

| Classification                         | Symbol                     | I/O    | Name                        | Function                                                                                  |
|----------------------------------------|----------------------------|--------|-----------------------------|-------------------------------------------------------------------------------------------|
| Bus control                            | $\overline{\text{WRH}}$    | Output | Write to upper byte         | Indicates a write access to bits 15 to 8 of data of external memory or device.            |
|                                        | $\overline{\text{WRL}}$    | Output | Write to lower byte         | Indicates a write access to bits 7 to 0 of data of external memory or device.             |
|                                        | DQMUU                      | Output | HH byte selection           | Selects bits D31 to D24 when SDRAM is connected.                                          |
|                                        | DQMUL                      | Output | HL byte selection           | Selects bits D23 to D16 when SDRAM is connected.                                          |
|                                        | DQMLU                      | Output | Upper byte selection        | Selects bits D15 to D8 when SDRAM is connected.                                           |
|                                        | DQMLL                      | Output | Lower byte selection        | Selects bits D7 to D0 when SDRAM is connected.                                            |
|                                        | $\overline{\text{RASU}}$   | Output | RAS                         | Connected to the $\overline{\text{RAS}}$ pin when SDRAM is connected.                     |
|                                        | $\overline{\text{CASU}}$   | Output | CAS                         | Connected to the $\overline{\text{CAS}}$ pin when SDRAM is connected.                     |
|                                        | $\overline{\text{RASL}}$   | Output | RAS                         | Connected to the $\overline{\text{RAS}}$ pin when SDRAM is connected.                     |
|                                        | $\overline{\text{CASL}}$   | Output | CAS                         | Connected to the $\overline{\text{CAS}}$ pin when SDRAM is connected.                     |
|                                        | CKE                        | Output | CK enable                   | Connected to the CKE pin when SDRAM is connected.                                         |
|                                        | $\overline{\text{REFOUT}}$ | Output | Refresh request output      | Request signal output for refresh execution while the bus mastership is released.         |
| Direct memory access controller (DMAC) | DREQ0 to DREQ3             | Input  | DMA-transfer request        | Input pins to receive external requests for DMA transfer.                                 |
|                                        | DACK0 to DACK3             | Output | DMA-transfer request accept | Output pins for signals indicating acceptance of external requests from external devices. |
|                                        | TEND1, TEND0               | Output | DMA-transfer end output     | Output pins for DMA transfer end.                                                         |

| Classification                           | Symbol                         | I/O   | Name                                          | Function                                                                                          |
|------------------------------------------|--------------------------------|-------|-----------------------------------------------|---------------------------------------------------------------------------------------------------|
| Multi-function timer pulse unit 2 (MTU2) | TCLKA, TCLKB, TCLKC, TCLKD     | Input | MTU2 timer clock input                        | External clock input pins for the timer.                                                          |
|                                          | TIOC0A, TIOC0B, TIOC0C, TIOC0D | I/O   | MTU2 input capture/output compare (channel 0) | The TGRA_0 to TGRD_0 input capture input/output compare output/PWM output pins.                   |
|                                          | TIOC1A, TIOC1B                 | I/O   | MTU2 input capture/output compare (channel 1) | The TGRA_1 and TGRB_1 input capture input/output compare output/PWM output pins.                  |
|                                          | TIOC2A, TIOC2B                 | I/O   | MTU2 input capture/output compare (channel 2) | The TGRA_2 and TGRB_2 input capture input/output compare output/PWM output pins.                  |
|                                          | TIOC3A, TIOC3B, TIOC3C, TIOC3D | I/O   | MTU2 input capture/output compare (channel 3) | The TGRA_3 to TGRD_3 input capture input/output compare output/PWM output pins.                   |
|                                          | TIOC4A, TIOC4B, TIOC4C, TIOC4D | I/O   | MTU2 input capture/output compare (channel 4) | The TGRA_4 and TGRD_4 input capture input/output compare output/PWM output pins.                  |
|                                          | TIC5U, TIC5V, TIC5W            | Input | MTU2 input capture (channel 5)                | The TGRU_5, TGRV_5, and TGRW_5 input capture input/dead time compensation input pins.             |
| Port output enable 2 (POE2)              | POE8, POE4 to POE0             | Input | Port output control                           | Request signal input to place the MTU2 and MTU2S waveform output pin in the high impedance state. |

|                                  | $\overline{\text{ASEBRK}}$                   | Input  | Break request             | E10A-USB emulator break input pin.                                           |
| User break controller (UBC)      | $\overline{\text{UBCTR}}\overline{\text{G}}$ | Output | User break trigger output | Trigger output pin for UBC condition match.                                  |

## Section 2 CPU

### 2.1 Data Formats

Figure 2.1 shows the data formats supported by the SH-2A/SH2A-FPU.

The CPU of SH7216 Group products (SH7216A, SH7216B, SH7216G and SH7216H) is the SH2A-FPU, and that of SH7214 Group products (SH7214A, SH7214B, SH7214G and SH7214H) is the SH-2A.

**Figure 2.1 Data Format**

## 2.2 Register Descriptions

### 2.2.1 General Registers

Figure 2.2 shows the general registers.

The general registers consist of 16 registers, numbered R0 to R15, and are used for data processing and address calculation. R0 is also used as an index register. Several instructions have R0 fixed as their only usable register. R15 is used as the hardware stack pointer (SP). Saving and restoring the status register (SR) and program counter (PC) in exception handling is accomplished by referencing the stack using R15.

**Figure 2.2 General Registers**

## 2.2.2 Control Registers

The control registers consist of four 32-bit registers: the status register (SR), the global base register (GBR), the vector base register (VBR), and the jump table base register (TBR).

The status register indicates instruction processing states.

The global base register functions as a base address for the GBR indirect addressing mode to transfer data to the registers of on-chip peripheral modules.

The vector base register functions as the base address of the exception handling vector area (including interrupts).

The jump table base register functions as the base address of the function table area.

**Figure 2.3 Control Registers**

**(1) Status Register (SR)**

| 3, 2     | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                              |
| 1        | S        | —             | R/W | S Bit<br>Specifies a saturation operation for a MAC instruction.                                                                                              |
| 0        | T        | —             | R/W | T Bit<br>True/false condition or carry/borrow bit                                                                                                             |

## (2) Global Base Register (GBR)

GBR is referenced as the base address in a GBR-referencing MOV instruction.

## (3) Vector Base Register (VBR)

VBR is referenced as the branch destination base address when an exception or an interrupt occurs.

## (4) Jump Table Base Register (TBR)

TBR is referenced as the start address of a function table located in memory in a JSR/N@ @(disp8,TBR) table-referencing subroutine call instruction.

### 2.2.3 System Registers

The system registers consist of four 32-bit registers: the high and low multiply and accumulate registers (MACH and MACL), the procedure register (PR), and the program counter (PC). MACH and MACL store the results of multiply or multiply and accumulate operations. PR stores the return address from a subroutine procedure. PC indicates the program address being executed and controls the flow of the processing.

**Figure 2.4 System Registers**

## (1) Multiply and Accumulate Register High (MACH) and Multiply and Accumulate Register Low (MACL)

MACH and MACL are used as the addition value in a MAC instruction, and store the result of a MAC or MUL instruction.

## (2) Procedure Register (PR)

PR stores the return address of a subroutine call using a BSR, BSRF, or JSR instruction, and is referenced by a subroutine return instruction (RTS).

## (3) Program Counter (PC)

PC indicates the address four bytes farther from that of the instruction being executed.

### 2.2.4 Floating-Point Registers

Figure 2.5 shows the floating-point registers. There are sixteen 32-bit floating-point registers, FPR0 to FPR15. These sixteen registers are referenced as FR0 to FR15, DR0, DR2, DR4, DR6, DR8, DR10, DR12, and DR14. The correspondence between FPRn and the referenced name is determined by the PR and SZ bits in FPSCR (see figure 2.5).

#### (1) Floating-Point Registers (FPRn: 16 registers)

FPR0, FPR1, FPR2, FPR3, FPR4, FPR5, FPR6, FPR7, FPR8, FPR9, FPR10, FPR11, FPR12, FPR13, FPR14, and FPR15

#### (2) Single-Precision Floating-Point Registers (FRi: 16 registers)

FR0 to FR15 are allocated to FPR0 to FPR15.

#### (3) Double-Precision Floating-Point Registers or Single-Precision Floating-Point Register Pairs (DRi: 8 registers)

A DR register is composed of two FR registers.

DR0 = {FPR0, FPR1}, DR2 = {FPR2, FPR3}, DR4 = {FPR4, FPR5}, DR6 = {FPR4, FPR5},  
DR8 = {FPR8, FPR9}, DR10 = {FPR10, FPR11}, DR12 = {FPR12, FPR13}, and DR14 =  
{FPR14, FPR15}

| Referenced Name                 |              | Register Name |
|---------------------------------|--------------|---------------|
| Transfer instruction:           | FPSCR.SZ = 0 | FPSCR.SZ = 1  |
| Arithmetic/logical instruction: | FPSCR.PR = 0 | FPSCR.PR = 1  |
| FR0                             | DR0          | FPR0          |
| FR1                             |              | FPR1          |
| FR2                             | DR2          | FPR2          |
| FR3                             |              | FPR3          |
| FR4                             | DR4          | FPR4          |
| FR5                             |              | FPR5          |
| FR6                             | DR6          | FPR6          |
| FR7                             |              | FPR7          |
| FR8                             | DR8          | FPR8          |
| FR9                             |              | FPR9          |
| FR10                            | DR10         | FPR10         |
| FR11                            |              | FPR11         |
| FR12                            | DR12         | FPR12         |
| FR13                            |              | FPR13         |
| FR14                            | DR14         | FPR14         |
| FR15                            |              | FPR15         |

**Figure 2.5 Floating-Point Registers**

**Programming Note:** The values of FPR0 to FPR15 are undefined after a reset.

### 2.2.5 Floating-Point System Registers

#### (1) Floating-Point Communication Register (FPUL)

Data is transferred between an FPU register and a CPU register via FPUL.

**(2) Floating Point Status/Control Register (FPSCR)**

**Table 2.1 Bit Allocation for FPU Exception Handling**

|        |                            | FPU Error (E) | Invalid Operation (V) | Division by 0 (Z) | Overflow (O) | Underflow (U) | Incorrect (I) |
|--------|----------------------------|---------------|-----------------------|-------------------|--------------|---------------|---------------|
| Cause  | FPU exception cause field  | Bit 17        | Bit 16                | Bit 15            | Bit 14       | Bit 13        | Bit 12        |
| Enable | FPU exception enable field | None          | Bit 11                | Bit 10            | Bit 9        | Bit 8         | Bit 7         |
| Flag   | FPU exception flag field   | None          | Bit 6                 | Bit 5             | Bit 4        | Bit 3         | Bit 2         |

Note: In the SH-2A, no FPU errors occur.

## 2.2.6 Register Bank

Using a register bank, high-speed register saving and restoration can be achieved for the 19 32-bit registers: general registers R0 to R14, control register GBR, and system registers MACH, MACL, and PR. The register contents are automatically saved in the bank after the CPU accepts an interrupt that uses the bank. Restoration from the bank is executed by a RESBANK instruction issued in an interrupt processing routine.

This LSI has 15 banks. For details, refer to the SH-2A, SH2A-FPU Software Manual.

## 2.2.7 Initial Values of Registers

Table 2.2 lists the values of the registers after a reset.

**Table 2.2 Initial Values of Registers**

| Classification                  | Register       | Initial Value                                                                              |
|---------------------------------|----------------|--------------------------------------------------------------------------------------------|
| General registers               | R0 to R14      | Undefined                                                                                  |
|                                 | R15 (SP)       | Value of the stack pointer in the vector address table                                     |
| Control registers               | SR             | Bits I[3:0] are 1111 (H'F), BO and CS are 0, reserved bits are 0, and others are undefined |
|                                 | GBR, TBR       | Undefined                                                                                  |

## 2.3 Data Formats

### 2.3.1 Data Format in Registers

Register operands are always longwords (32 bits). If the size of a memory operand is a byte (8 bits) or a word (16 bits), it is changed into a longword through sign extension or zero extension when loaded into a register.

**Figure 2.6 Data Format in Registers**

### 2.3.2 Data Formats in Memory

Memory data formats are classified into bytes, words, and longwords. Memory can be accessed in 8-bit bytes, 16-bit words, or 32-bit longwords. A memory operand of fewer than 32 bits is stored in a register in sign-extended or zero-extended form.

A word operand should be accessed at a word boundary (an even address of multiple of two bytes: address  $2n$ ), and a longword operand at a longword boundary (an even address of multiple of four bytes: address  $4n$ ). Otherwise, an address error will occur. A byte operand can be accessed at any address.

Only big-endian byte order can be selected for the data format.

Data formats in memory are shown in figure 2.7.

**Figure 2.7 Data Formats in Memory**

### 2.3.3 Immediate Data Format

Byte (8-bit) immediate data is located in an instruction code. Immediate data accessed by the MOV, ADD, and CMP/EQ instructions is sign-extended and handled in registers as longword data. Immediate data accessed by the TST, AND, OR, and XOR instructions is zero-extended and handled as longword data. Consequently, AND instructions with immediate data always clear the upper 24 bits of the destination register.

20-bit immediate data is located in the code of a MOVI20 or MOVI20S 32-bit transfer instruction. The MOVI20 instruction stores immediate data in the destination register in sign-extended form. The MOVI20S instruction shifts immediate data by eight bits in the upper direction, and stores it in the destination register in sign-extended form.

Word or longword immediate data is not located in the instruction code, but rather is stored in a memory table. The memory table is accessed by an immediate data transfer instruction (MOV) using the PC relative addressing mode with displacement.

See examples given in section 2.4.1 (10), Immediate Data.

## 2.4 Instruction Features

### 2.4.1 RISC-Type Instruction Set

The CPU has a RISC-type instruction set, which features following functions.

#### (1) 16-Bit Fixed-Length Instructions

Basic instructions have a fixed length of 16 bits, improving program code efficiency.

#### (2) 32-Bit Fixed-Length Instructions

The SH-2A/SH2A-FPU additionally features 32-bit fixed-length instructions, improving performance and ease of use.

#### (3) One Instruction per Cycle

Each basic instruction can be executed in one cycle using the pipeline system.

#### (4) Data Length

The standard data length for all operations is a longword. Memory can be accessed in bytes, words, or longwords. Byte or word data in memory is sign-extended and handled as longword data. Immediate data is sign-extended for arithmetic operations or zero-extended for logic operations. It is also handled as longword data.

**Table 2.3 Sign Extension of Word Data**

| SH2-A/SH2A-FPU CPU       | Description                                                                                                  | Example of Other CPU |
|--------------------------|--------------------------------------------------------------------------------------------------------------|----------------------|
| MOV.W    @(disp, PC), R1 | Data is sign-extended to 32 bits, and R1 becomes H'00001234. It is next operated upon by an ADD instruction. | ADD.W    #H'1234, R0 |
| ADD       R1, R0         |                                                                                                              |                      |
| .....                    |                                                                                                              |                      |
| .DATA.W   H'1234         |                                                                                                              |                      |

Note: @(disp, PC) accesses the immediate data.

#### (5) Load-Store Architecture

Basic operations are executed between registers. For operations that involve memory access, data is loaded to the registers and executed (load-store architecture). Instructions such as AND that manipulate bits, however, are executed directly in memory.

## (6) Delayed Branch Instructions

With the exception of some instructions, unconditional branch instructions, etc., are executed as delayed branch instructions. With a delayed branch instruction, the branch is taken after execution of the instruction immediately following the delayed branch instruction. This reduces disturbance of the pipeline control when a branch is taken.

In a delayed branch, the actual branch operation occurs after execution of the slot instruction. However, instruction execution such as register updating excluding the actual branch operation, is performed in the order of delayed branch instruction → delay slot instruction. For example, even though the contents of the register holding the branch destination address are changed in the delay slot, the branch destination address remains as the register contents prior to the change.

**Table 2.4 Delayed Branch Instructions**

| SH2-A/SH2A-FPU CPU |        | Description                                 | Example of Other CPU |        |
|--------------------|--------|---------------------------------------------|----------------------|--------|
| BRA                | TRGET  | Executes the ADD before branching to TRGET. | ADD.W                | R1, R0 |
| ADD                | R1, R0 |                                             | BRA                  | TRGET  |

## (7) Unconditional Branch Instructions with No Delay Slot

The SH-2A/SH2A-FPU additionally features unconditional branch instructions in which a delay slot instruction is not executed. This eliminates unnecessary NOP instructions, and so reduces the code size.

## (8) Multiply/Multiply-and-Accumulate Operations

16-bit × 16-bit → 32-bit multiply operations are executed in one to two cycles. 16-bit × 16-bit + 64-bit → 64-bit multiply-and-accumulate operations are executed in two to three cycles. 32-bit × 32-bit → 64-bit multiply and 32-bit × 32-bit + 64-bit → 64-bit multiply-and-accumulate operations are executed in two to four cycles.

## (9) T Bit

The T bit in the status register (SR) changes according to the result of the comparison. Whether a conditional branch is taken or not taken depends upon the T bit condition (true/false). The number of instructions that change the T bit is kept to a minimum to improve the processing speed.

**Table 2.5 T Bit**

| SH2-A/SH2A-FPU CPU |         | Description                                                                     | Example of Other CPU |        |
|--------------------|---------|---------------------------------------------------------------------------------|----------------------|--------|
| CMP/GE             | R1, R0  | T bit is set when $R0 \geq R1$ .                                                | CMP.W                | R1, R0 |
| BT                 | TRGET0  | The program branches to TRGET0 when $R0 \geq R1$ and to TRGET1 when $R0 < R1$ . | BGE                  | TRGET0 |
| BF                 | TRGET1  |                                                                                 | BLT                  | TRGET1 |
| ADD                | #-1, R0 | T bit is not changed by ADD.                                                    | SUB.W                | #1, R0 |
| CMP/EQ             | #0, R0  | T bit is set when $R0 = 0$ .                                                    | BEQ                  | TRGET  |
| BT                 | TRGET   | The program branches if $R0 = 0$ .                                              |                      |        |

**(10) Immediate Data**

Byte immediate data is located in an instruction code. Word or longword immediate data is not located in instruction codes but in a memory table. The memory table is accessed by an immediate data transfer instruction (MOV) using the PC relative addressing mode with displacement.

With the SH-2A/SH2A-FPU, 17- to 28-bit immediate data can be located in an instruction code. However, for 21- to 28-bit immediate data, an OR instruction must be executed after the data is transferred to a register.

**Table 2.6 Immediate Data Accessing**

| Classification   | SH-2A/SH2A-FPU CPU |                 | Example of Other CPU |                 |
|------------------|--------------------|-----------------|----------------------|-----------------|
| 8-bit immediate  | MOV                | #H'12, R0       | MOV.B                | #H'12, R0       |
| 16-bit immediate | MOVI20             | #H'1234, R0     | MOV.W                | #H'1234, R0     |
| 20-bit immediate | MOVI20             | #H'12345, R0    | MOV.L                | #H'12345, R0    |
| 28-bit immediate | MOVI20S            | #H'12345, R0    | MOV.L                | #H'1234567, R0  |
|                  | OR                 | #H'67, R0       |                      |                 |
| 32-bit immediate | MOV.L              | @(disp, PC), R0 | MOV.L                | #H'12345678, R0 |
|                  | .....<br>.DATA.L   | H'12345678      |                      |                 |

Note: @(disp, PC) accesses the immediate data.

(11) Absolute Address

When data is accessed by an absolute address, the absolute address value should be placed in the memory table in advance. That value is transferred to the register by loading the immediate data during the execution of the instruction, and the data is accessed in register indirect addressing mode.

With the SH-2A/SH2A-FPU, when data is referenced using an absolute address not exceeding 28 bits, it is also possible to transfer immediate data located in the instruction code to a register and to reference the data in register indirect addressing mode. However, when referencing data using an absolute address of 21 to 28 bits, an OR instruction must be used after the data is transferred to a register.

Table 2.7 Absolute Address Accessing

| Classification  | SH-2A/SH2A-FPU CPU |               | Example of Other CPU |
|-----------------|--------------------|---------------|----------------------|
| Up to 20 bits   | MOVI20             | #H'12345,R1   | MOV.B @H'12345,R0    |
|                 | MOV.B              | @R1,R0        |                      |
| 21 to 28 bits   | MOVI20S            | #H'12345,R1   | MOV.B @H'1234567,R0  |
|                 | OR                 | #H'67,R1      |                      |
|                 | MOV.B              | @R1,R0        |                      |
| 29 bits or more | MOV.L              | @(disp,PC),R1 | MOV.B @H'12345678,R0 |
|                 | MOV.B              | @R1,R0        |                      |
|                 | .....              |               |                      |
|                 | .DATA.L            | H'12345678    |                      |

(12) 16-Bit/32-Bit Displacement

When data is accessed by 16-bit or 32-bit displacement, the displacement value should be placed in the memory table in advance. That value is transferred to the register by loading the immediate data during the execution of the instruction, and the data is accessed in the indexed indirect register addressing mode.

Table 2.8 Displacement Accessing

| Classification      | SH-2A/SH2A-FPU CPU |               | Example of Other CPU  |
|---------------------|--------------------|---------------|-----------------------|
| 16-bit displacement | MOV.W              | @(disp,PC),R0 | MOV.W @(H'1234,R1),R2 |
|                     | MOV.W              | .(R0,R1),R2   |                       |
|                     |                    | .....         |                       |
|                     | .DATA.W            | H'1234        |                       |

2.4.2 Addressing Modes

The addressing modes and effective address calculation methods are listed below.

Table 2.9 Addressing Modes and Effective Addresses

| Addressing Mode                       | Instruction Format | Effective Address Calculation                                                                                                                                                                                                                                                                                         | Equation                                                                                                        |
|---------------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| Register direct                       | Rn                 | The effective address is register Rn. (The operand is the contents of register Rn.)                                                                                                                                                                                                                                   | —                                                                                                               |
| Register indirect                     | @Rn                | The effective address is the contents of register Rn.<br>                                                                                                                                                                            | Rn                                                                                                              |
| Register indirect with post-increment | @Rn+               | The effective address is the contents of register Rn.<br>A constant is added to the contents of Rn after the instruction is executed. 1 is added for a byte operation, 2 for a word operation, and 4 for a longword operation.<br> | Rn<br>(After instruction execution)<br>Byte:<br>Rn + 1 → Rn<br>Word:<br>Rn + 2 → Rn<br>Longword:<br>Rn + 4 → Rn |

| Addressing Mode                      | Instruction Format | Effective Address Calculation                                                                                                                                                                                                                                                                                                 | Equation                                                                                                                                                                                                                         |
|--------------------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Register indirect with pre-decrement | @-Rn               | <p>The effective address is the value obtained by subtracting a constant from Rn. 1 is subtracted for a byte operation, 2 for a word operation, and 4 for a longword operation.</p>                                                          | <p>Byte:<br/> <math>Rn - 1 \rightarrow Rn</math></p> <p>Word:<br/> <math>Rn - 2 \rightarrow Rn</math></p> <p>Longword:<br/> <math>Rn - 4 \rightarrow Rn</math><br/> (Instruction is executed with Rn after this calculation)</p> |
| Register indirect with displacement  | @(disp:4, Rn)      | <p>The effective address is the sum of Rn and a 4-bit displacement (disp). ### 2.4.3 Instruction Format

The instruction formats and the meaning of source and destination operands are described below. The meaning of the operand depends on the instruction code. The symbols used are as follows:

- xxxx: Instruction code
- mmmm: Source register
- nnnn: Destination register
- iiii: Immediate data
- dddd: Displacement

**Table 2.10 Instruction Formats**

| Instruction Formats                                                                       | Source Operand                              | Destination Operand                           | Example            |

Note: \* In multiply-and-accumulate instructions, nnnn is the source register.

## 2.5 Instruction Set

### 2.5.1 Instruction Set by Classification

Table 2.11 lists the instructions according to their classification.

**Table 2.11 Classification of Instructions**

| Classification | Types | Operation Code | Function                                        | No. of Instructions |
|----------------|-------|----------------|-------------------------------------------------|---------------------|
| Data transfer  | 13    | MOV            | Data transfer                                   | 62                  |
|                |       |                | Immediate data transfer                         |                     |
|                |       |                | Peripheral module data transfer                 |                     |
|                |       |                | Structure data transfer                         |                     |
|                |       |                | Reverse stack transfer                          |                     |
|                |       | MOVA           | Effective address transfer                      |                     |
|                |       | MOVI20         | 20-bit immediate data transfer                  |                     |
|                |       | MOVI20S        | 20-bit immediate data transfer                  |                     |
|                |       |                | 8-bit left-shift                                |                     |
|                |       | MOVML          | R0–Rn register save/restore                     |                     |
|                |       | MOV MU         | Rn–R14 and PR register save/restore             |                     |
|                |       | MOV RT         | T bit inversion and transfer to Rn              |                     |
|                |       | MOV T          | T bit transfer                                  |                     |
|                |       | MOV U          | Unsigned data transfer                          |                     |
|                |       | NOTT           | T bit inversion                                 |                     |
|                |       | PREF           | Prefetch to operand cache                       |                     |
|                |       | SWAP           | Swap of upper and lower bytes                   |                     |
|                |       | XTRCT          | Extraction of the middle of registers connected |                     |

| Classification        | Types | Operation Code | Function                                                                    | No. of Instructions |
|-----------------------|-------|----------------|-----------------------------------------------------------------------------|---------------------|
| Arithmetic operations | 26    | ADD            | Binary addition                                                             | 40                  |
|                       |       | ADDC           | Binary addition with carry                                                  |                     |
|                       |       | ADDV           | Binary addition with overflow check                                         |                     |
|                       |       | CMP/cond       | Comparison                                                                  |                     |

The table below shows the format of instruction codes, operation, and execution states. They are described by using this format according to their classification.

| Instruction              | Instruction Code              | Operation                           | Execution Cycles                          | T Bit                                         |
|--------------------------|-------------------------------|-------------------------------------|-------------------------------------------|-----------------------------------------------|
| Indicated by mnemonic.   | Indicated in MSB ↔ LSB order. | Indicates summary of operation.     | Value when no wait states are inserted.*1 | Value of T bit after instruction is executed. |
| [Legend]                 | [Legend]                      | [Legend]                            |                                           | [Legend]                                      |
| OP: Sz SRC, DEST         | mmmm: Source register         | →, ←: Transfer direction            |                                           | —: No change                                  |

| disp: Displacement*2     |                               | <<n: n-bit left shift               |                                           |                                               |
|                          |                               | >>n: n-bit right shift              |                                           |                                               |

Notes: 1. Instruction execution cycles: The execution cycles shown in the table are minimums. In practice, the number of instruction execution states will be increased in cases such as the following:

- a. When there is a conflict between an instruction fetch and a data access
  - b. When the destination register of a load instruction (memory → register) is the same as the register used by the next instruction.
2. Depending on the operand size, displacement is scaled by ×1, ×2, or ×4. For details, refer to the SH-2A, SH2A-FPU Software Manual.

## 2.5.2 Data Transfer Instructions

**Table 2.12 Data Transfer Instructions**

Notes: Instruction execution cycles: The execution cycles shown in the table are minimums. In practice, the number of instruction execution states in cases such as the following:

- When there is a conflict between an instruction fetch and a data access
- When the destination register of a load instruction (memory → register) is the same as the register used by the next instruction.

\* In the event of bank overflow, the number of cycles is 19.

## 2.5.8 Floating-Point Operation Instructions

**Table 2.18 Floating-Point Operation Instructions**

| Instruction |               | Instruction Code   | Operation             | Execution Cycles | T Bit             | Compatibility |     |                        |

## 2.6 Processing States

The CPU has four processing states: reset, exception handling, program execution, and power-down. Figure 2.8 shows the transitions between the states.

**Figure 2.8 Transitions between Processing States**

### **(1) Reset State**

In this state, the CPU is reset. There are two kinds of reset, power-on reset and manual reset.

### **(2) Exception Handling State**

The exception handling state is a transient state that occurs when exception handling sources such as resets or interrupts alters the CPU's processing state flow.

For a reset, the initial values of the program counter (PC) (execution start address) and stack pointer (SP) are fetched from the exception handling vector table and stored; the CPU then branches to the execution start address and execution of the program begins.

For an interrupt, the stack pointer (SP) is accessed and the program counter (PC) and status register (SR) are saved to the stack area. The exception service routine start address is fetched from the exception handling vector table; the CPU then branches to that address and the program starts executing, thereby entering the program execution state.

### **(3) Program Execution State**

In the program execution state, the CPU sequentially executes the program.

### **(4) Power-Down State**

In the power-down state, the CPU stops operating to reduce power consumption. The SLEEP instruction places the CPU in the sleep mode or the software standby mode.

## Section 3 MCU Operating Modes

### 3.1 Selection of Operating Modes

This LSI has four MCU operating modes and three on-chip flash memory programming modes. The operating mode is determined by the setting of FWE, MD1, and MD0 pins. Table 3.1 shows the allowable combinations of these pin settings; do not set these pins in the other way than the shown combinations.

When power is applied to the system, be sure to conduct power-on reset.

The MCU operating mode can be selected from MCU extension modes 0 to 2 and single chip mode. For the on-chip flash memory programming mode, boot mode, user boot mode, and user program mode which are on-chip programming modes are available.

**Table 3.1 Selection of Operating Modes**

| Mode No.                            | Pin Setting |     |     | Mode Name            | On-Chip ROM | Bus Width of CS0 Space |
|-------------------------------------|-------------|-----|-----|----------------------|-------------|------------------------|
|                                     | FWE         | MD1 | MD0 |                      |             |                        |
| Mode 0                              | 0           | 0   | 0   | MCU extension mode 0 | Not active  | 32                     |
| Mode 1                              | 0           | 0   | 1   | MCU extension mode 1 | Not active  | 16                     |
| Mode 2                              | 0           | 1   | 0   | MCU extension mode 2 | Active      | Set by CS0BCR in BSC   |
| Mode 3                              | 0           | 1   | 1   | Single chip mode     | Active      | —                      |
| Mode 4* <sup>1</sup>                | 1           | 0   | 0   | Boot mode            | Active      | Set by CS0BCR in BSC   |
| Mode 5* <sup>1</sup>                | 1           | 0   | 1   | User boot mode       | Active      | Set by CS0BCR in BSC   |
| Mode 6* <sup>1</sup>                | 1           | 1   | 0   | User program mode    | Active      | Set by CS0BCR in BSC   |
| Mode 7* <sup>1</sup> * <sup>2</sup> | 1           | 1   | 1   | USB boot mode        | Active      | —                      |
| Mode 7* <sup>1</sup> * <sup>3</sup> | 1           | 1   | 1   | User program mode    | Active      | —                      |

Notes: 1. Flash memory programming mode.  
 2. When always FWE = 1, after the power has been on.  
 3. If FWE = 0 when power-on reset has been released, and if FWE = 1 when the MCU operation has been set, transition to the user program mode is executed in a single chip state.

## 3.2 Input/Output Pins

Table 3.2 describes the configuration of operating mode related pin.

**Table 3.2 Pin Configuration**

| Pin Name | Input/Output | Function                                                              |
|----------|--------------|-----------------------------------------------------------------------|
| MD0      | Input        | Designates operating mode through the level applied to this pin       |
| MD1      | Input        | Designates operating mode through the level applied to this pin       |
| FWE      | Input        | Enables, by hardware, programming/erasing of the on-chip flash memory |

## 3.3 Operating Modes

### 3.3.1 Mode 0 (MCU Extension Mode 0)

In this mode, CS0 space becomes external memory spaces with 32-bit bus width.

### 3.3.2 Mode 1 (MCU Extension Mode 1)

In this mode, CS0 space becomes external memory spaces with 16-bit bus width.

### 3.3.3 Mode 2 (MCU Extension Mode 2)

The on-chip ROM is active and CS0 space can be used in this mode.

### 3.3.4 Mode 3 (Single Chip Mode)

All ports can be used in this mode, however the external address cannot be used.

### 3.4 Address Map

The address map for the operating modes is shown in figures 3.1 to 3.3.

| Modes 0 and 1<br>On-chip flash memory disabled mode |               | Mode 2<br>On-chip flash memory enabled mode |                                    | Mode 3<br>Single chip mode |                                    |

Figure 3.3 Address Map (512-Kbyte Version)

### 3.5 Initial State in This LSI

In the initial state of this LSI, some of on-chip modules are set in module standby state for saving power. When operating these modules, clear module standby state according to the procedure in section 30, Power-Down Modes.

### 3.6 Note on Changing Operating Mode

When changing operating mode while power is applied to this LSI, make sure to do it in the power-on reset state (that is, the low level is applied to the  $\overline{\text{RES}}$  pin).

**Figure 3.4 Reset Input Timing when Changing Operating Mode**

## Section 4 Clock Pulse Generator (CPG)

This LSI has a clock pulse generator (CPG) that generates an internal clock ( $I\phi$ ), a peripheral clock ( $P\phi$ ), a bus clock ( $B\phi$ ), an MTU2S clock ( $M\phi$ ), and an AD clock ( $A\phi$ ). The CPG consists of a crystal oscillator, a PLL circuit, and a divider circuit.

### 4.1 Features

- Five clocks generated independently

An internal clock ( $I\phi$ ) for the CPU and cache, a peripheral clock ( $P\phi$ ) for the peripheral modules, a bus clock ( $B\phi = CK$ ) for the external bus interface, an MTU2S clock ( $M\phi$ ) for the MTU2S module, and an AD clock ( $A\phi$ ) for the ADC module can be generated independently.

- Frequency change function

Internal and peripheral clock frequencies can be changed independently using the PLL (phase locked loop) circuit and divider circuit within the CPG. Frequencies are changed by software using frequency control register (FRQCR) settings.

- Power-down mode control

The clock can be stopped for sleep mode and software standby mode, and specific modules can be stopped using the module standby function. For details on clock control in the power-down modes, see section 30, Power-Down Modes.

Figure 4.1 shows a block diagram of the clock pulse generator.

**Figure 4.1 Block Diagram of Clock Pulse Generator**

The clock pulse generator blocks function as follows:

### **(1) PLL Circuit**

The PLL circuit multiplies the input clock frequency from the crystal oscillator or EXTAL pin by 16.

### **(2) Crystal Oscillator**

The crystal oscillator is an oscillation circuit in which a crystal resonator is connected to the XTAL pin or EXTAL pin. This can be used according to the clock operating mode.

### **(3) Divider**

The divider generates a clock signal at the operating frequency used by the internal clock ( $I\phi$ ), bus clock ( $B\phi$ ), peripheral clock ( $P\phi$ ), MTU2S clock ( $M\phi$ ), or AD clock ( $A\phi$ ). The operating frequency can be 1, 1/2, 1/4, or 1/8 times the output frequency of the PLL circuit. The division ratio is set in the frequency control register (FRQCR). USB clock ( $U\phi$ ) is set as fixed 1/4 and when generating USB clock with a divider, set the crystal resonator to 12 MHz.

### **(4) Clock Frequency Control Circuit**

The clock frequency control circuit controls the clock frequency using the frequency control register (FRQCR).

### **(5) Standby Control Circuit**

The standby control circuit controls the states of the clock pulse generator and other modules during clock switching, or sleep or software standby mode.

### **(6) Frequency Control Register (FRQCR)**

The frequency control register (FRQCR) has control bits assigned for the following functions: the frequency division ratios of the internal clock ( $I\phi$ ), bus clock ( $B\phi$ ), and peripheral clock ( $P\phi$ ).

### **(7) MTU2S Clock Frequency Control Register (MCLKCR)**

The MTU2S clock frequency control register (MCLKCR) has control bits assigned for the following function: the frequency division ratio of the MTU2S clock ( $M\phi$ ).

### **(8) AD Clock Frequency Control Register (ACLKCR)**

The AD clock frequency control register (ACLKCR) has control bits assigned for the following functions: the frequency division ratio of the AD clock ( $A\phi$ ).

### **(9) Standby Control Register**

The standby control register has bits for controlling the power-down modes and for selecting the USB clock. See section 30, Power-Down Modes, for more information.

### **(10) Oscillation Stop Detection Control Register (OSCCR)**

The oscillation stop detection control register (OSCCR) has an oscillation stop detection flag and a bit for selecting flag status output through an external pin.

### **(11) USB-only oscillator**

The oscillator for USB clock only that is connected to the resonator of 48 MHz.

## 4.2 Input/Output Pins

Table 4.1 lists the clock pulse generator pins and their functions.

**Table 4.1 Pin Configuration and Functions of the Clock Pulse Generator**

| Pin Name                                             | Symbol   | I/O    | Function                                                                                                                                     |
|------------------------------------------------------|----------|--------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Crystal input/output pins (clock input pins)         | XTAL     | Output | Connected to the crystal resonator. (Leave this pin open when the crystal resonator is not in use.)                                          |
|                                                      | EXTAL    | Input  | Connected to the crystal resonator or used to input an external clock.                                                                       |
| Clock output pin                                     | CK       | Output | Clock output pin. This pin can be placed in high-impedance state.                                                                            |
| Crystal input/output pins for USB (clock input pins) | USBXTAL  | Output | Connected to the crystal resonator for USB (equivalent for CSTCZ48M0X11R). Leave this pin open when the crystal resonator is not in use.     |
|                                                      | USBEXTAL | Input  | Connected to the crystal resonator for USB (equivalent for CSTCZ48M0X11R). Connect this pin to Vss when the crystal resonator is not in use. |

To use the clock output (CK) pin, appropriate settings may be needed in the pin function controller (PFC) in some cases. For details, refer to section 22, Pin Function Controller (PFC).

### 4.3 Clock Operating Modes

Table 4.2 shows the clock operating modes of this LSI.

**Table 4.2 Clock Operating Modes**

| Mode | Clock I/O                        |        | PLL Circuit        | Input to Divider |
|------|----------------------------------|--------|--------------------|------------------|
|      | Source                           | Output |                    |                  |
| 1    | EXTAL input or crystal resonator | CK*    | On ( $\times 16$ ) | $\times 16$      |

Note: \* To output the clock through the CK pin, appropriate settings should be made in the PFC. For details, refer to section 22, Pin Function Controller (PFC).

The frequency of the external clock input from the EXTAL pin is multiplied by 16 in the PLL circuit before it is supplied to the on-chip modules in this LSI, which eliminates the need to generate a high-frequency clock outside the LSI. Since the input clock frequency ranging from 10 MHz to 12.5 MHz can be used, the internal clock ( $I\phi$ ) frequency ranges from 20 MHz to 200 MHz or 100 MHz.

Maximum operating frequencies\*:

$I\phi = 200 \text{ MHz}/100 \text{ MHz}$ ,  $B\phi = 50 \text{ MHz}$ ,  $P\phi = 50 \text{ MHz}$ ,  $M\phi = 100 \text{ MHz}$ ,  $A\phi = 50 \text{ MHz}$

Table 4.3 shows an example of a range for the frequency division ratios that can be specified with FRQCR.

Note: \* The 200-MHz  $I\phi$  applies to the SH7216A, SH7214A, SH7216B, and SH7214B.  
The 100-MHz  $I\phi$  applies to the SH7216G, SH7214G, SH7216H, and SH7214H.

**Table 4.3 Example of Relationship between Clock Operating Mode and Frequency Range**

| PLL<br>Multipli-<br>cation<br>Ratio | FRQCR/MCLKCR/ACLKCR |     |     |     |     | Division Ratio Setting |    |    |    |    | Clock Ratio |     |    |    |    | Clock Frequency (MHz)* |  |  |  |  |
|-------------------------------------|---------------------|-----|-----|-----|-----|------------------------|----|----|----|----|-------------|-----|----|----|----|------------------------|--|--|--|--|
|                                     |                     |     |     |     |     |                        |    |    |    |    |             |     |    |    |    |                        |  |  |  |  |

Notes: \* Clock frequencies when the input clock frequency is assumed to be the shown value.

1. The PLL multiplication ratio is fixed at ×16. The division ratio can be selected from ×1, ×1/2, ×1/4, and ×1/8 for each clock by the setting in the frequency control register.
2. The output frequency of the PLL circuit is obtained by multiplication of the frequency of the input from the crystal resonator or EXTAL pin and the multiplication ratio (×16) of the PLL circuit. This output frequency must be 200 MHz or lower.
3. The input to the divider is always the output from the PLL circuit.
4. The internal clock (I $\phi$ ) frequency is obtained by multiplication of the frequency of the input from the crystal resonator or EXTAL pin, the multiplication ratio (×16) of the PLL circuit, and the division ratio of the divider. The resultant frequency of the internal clock (I $\phi$ ) must not exceed 200 MHz or 100 MHz (maximum operating frequency) or lower.
5. The bus clock (B $\phi$ ) frequency is obtained by multiplication of the frequency of the input from the crystal resonator or EXTAL pin, the multiplication ratio (×16) of the PLL circuit, and the division ratio of the divider. The resultant frequency of the bus clock (B $\phi$ ) must not exceed 50 MHz or the internal clock (I $\phi$ ) frequency.
6. The peripheral clock (P $\phi$ ) frequency is obtained by multiplication of the frequency of the input from the crystal resonator or EXTAL pin, the multiplication ratio (×16) of the PLL circuit, and the division ratio of the divider. The resultant frequency of the peripheral clock (P $\phi$ ) must not exceed 50 MHz or the bus clock (B $\phi$ ) frequency.

7. When using the MTU2S, the MTU2S clock ( $M\phi$ ) frequency must not exceed 100 MHz and exceed the  $P\phi$  and  $B\phi$  frequencies. The MTU2S clock ( $M\phi$ ) frequency is obtained by multiplication of the frequency of the input from the crystal resonator or EXTAL pin, the multiplication ratio ( $\times 16$ ) of the PLL circuit, and the division ratio of the divider.
8. The frequency of the CK pin output is always equal to the bus clock ( $B\phi$ ) frequency.
9. When using the AD, the AD clock ( $A\phi$ ) frequency must be equal to or higher than the peripheral clock ( $P\phi$ ) frequency.
10. When using the USB, the peripheral clock ( $P\phi$ ) frequency must be 13 MHz or higher.
11.  $U\phi$  must be fixed to 48 MHz. When generating  $U\phi$  from the divider, input the clock 12 MHz or connect the crystal resonator of 12MHz to the EXTAL or XTAL.

## 4.4 Register Descriptions

The clock pulse generator has the following registers.

**Table 4.4 Register Configuration**

| Register Name                               | Abbreviation | R/W | Initial Value | Address    | Access Size |
|---------------------------------------------|--------------|-----|---------------|------------|-------------|
| Frequency control register                  | FRQCR        | R/W | H'0535        | H'FFFE0010 | 16          |
| MTU2S clock frequency control register      | MCLKCR       | R/W | H'43          | H'FFFE0410 | 8           |
| AD clock frequency control register         | ACLKCR       | R/W | H'43          | H'FFFE0414 | 8           |
| Oscillation stop detection control register | OSCCR        | R/W | H'00          | H'FFFE001C | 8           |

### 4.4.1 Frequency Control Register (FRQCR)

FRQCR is a 16-bit readable/writable register used to specify the frequency division ratios for the internal clock ( $I\phi$ ), bus clock ( $B\phi$ ), and peripheral clock ( $P\phi$ ). FRQCR is only accessible in word units. After setting FRQCR to a new value, read it to confirm that it actually holds the new value, then execute NOP instructions for 32 cycles of  $P\phi$ . Additionally, make settings for individual modules after setting FRQCR.

FRQCR is initialized to H'0535 only by a power-on reset. FRQCR retains its previous value by a manual reset or in software standby mode. The previous value is also retained when an internal reset is triggered by an overflow of the WDT.

When switching the division ratio of bus clock frequency, the CK pin is fixed at low level for a cycle of an input clock so as to prevent a hazard of switching. To change the frequency, see section 4.5, Changing the Frequency.

#### 4.4.2 MTU2S Clock Frequency Control Register (MCLKCR)

MCLKCR is an 8-bit readable/writable register. MCLKCR can be accessed only in byte units.

MCLKCR is initialized to H'43 only by a power-on reset. MCLKCR retains its previous value by a manual reset or in software standby mode.

## 4.5 Changing the Frequency

Selecting division ratios for the frequency divider can change the frequencies of the internal clock, bus clock, peripheral clock, MTU2S clock, and AD clock under the software control through the frequency control register (FRQCR), MTU2S clock frequency control register (MCKCR), and AD clock frequency control register (ACLKCR). The following describes how to specify the frequencies.

1. In the initial state,  $IFC2$  to  $IFC0 = B'011$  ( $\times 1/4$ ),  $STC2$  to  $STC0 = B'101$  ( $\times 1/8$ ),  $PFC2$  to  $PFC0 = B'101$  ( $\times 1/8$ ),  $MSDIVS1$  and  $MSDIVS0 = 11$  ( $\times 1/4$ ), and  $ASDIVS1$  and  $ASDIVS0 = 11$  ( $\times 1/4$ ).
2. Stop all modules except the CPU, on-chip ROM, and on-chip RAM.
3. Set the desired values in bits  $IFC2$  to  $IFC0$ ,  $STC2$  to  $STC0$ ,  $PFC2$  to  $PFC0$ ,  $MSDIVS1$ ,  $MSDIVS0$ ,  $ASDIVS1$ , and  $ASDIVS0$ . When specifying the frequencies, satisfy the following condition: internal clock ( $I\phi$ )  $\geq$  bus clock ( $B\phi$ )  $\geq$  peripheral clock ( $P\phi$ ). When using the MTU2S clock, specify the frequencies to satisfy the following condition:  $100\text{ MHz} \geq \text{MTU2S clock (MI}\phi) \geq \text{peripheral clock (P}\phi)$ .
4. The clock frequencies are immediately changed to the specified values after FRQCR setting is completed.
5. When changing the frequency division ratio for  $B\phi$  after having set the ratios for  $B\phi$  and  $P\phi$  to  $1/4$  or a higher value, follow the procedure below rather than simultaneously changing the ratios for  $I\phi$ ,  $B\phi$ , and  $P\phi$ .
  1. Change only the ratio of  $P\phi$  to  $1/8$  ( $PFC$  in  $FRQCR = B'101$ ).
  2. After switching the setting for  $P\phi$ , set only the ratio for  $B\phi$  to the desired value.
  3. Set the ratios for  $I\phi$  and  $P\phi$  to the desired values.

The limitation only applies to changes to the ratio for  $B\phi$ . No limitation applies to procedures for changing  $I\phi$  and  $P\phi$ . Furthermore, no limitation applies to procedures for changing the ratios for  $I\phi$ ,  $B\phi$ , and  $P\phi$  from the initial values to desired values. Simultaneously changing settings for  $I\phi$ ,  $B\phi$ , and  $P\phi$  is possible. Note that FRQCR values should be changed by program code in the on-chip RAM. Even if FRQCR values are changed from initial ones. It is also changed by program code in the on-chip RAM.

# 4.6 Oscillator

The source of clock supply can be selected from a connected crystal resonator or an external clock input through a pin.

## 4.6.1 Connecting Crystal Resonator

A crystal resonator can be connected as shown in figure 4.2. Use the damping resistance ( $R_d$ ) shown in table 4.5. Use a crystal resonator that has a resonance frequency of 10 to 12.5 MHz.

It is recommended to consult the crystal resonator manufacturer concerning the compatibility of the crystal resonator and the LSI.

**Figure 4.2 Example of Crystal Resonator Connection**

**Table 4.5 Damping Resistance Values (Reference Values)**

| Frequency (MHz)                      | 10 | 12.5 |
|--------------------------------------|----|------|
| $R_d$ ( $\Omega$ ) (reference value) | 0  | 0    |

Figure 4.3 shows an equivalent circuit of the crystal resonator. Use a crystal resonator with the characteristics shown in table 4.6.

**Figure 4.3 Crystal Resonator Equivalent Circuit**

**Table 4.6 Crystal Resonator Characteristics**

|                                           |    |      |
|-------------------------------------------|----|------|
| Frequency (MHz)                           | 10 | 12.5 |
| $R_s$ max. ( $\Omega$ ) (reference value) | 60 | 50   |
| $C_0$ max. (pF) (reference value)         | 7  | 7    |

**4.6.2 External Clock Input Method**

Figure 4.4 shows an example of an external clock input connection. Drive the external clock high when it is stopped in software standby mode. During operation, input an external clock with a frequency of 10 to 12.5 MHz. Make sure the parasitic capacitance of the XTAL pin is 10 pF or less.

Even when inputting an external clock, be sure to wait at least for the oscillation settling time in power-on sequence or in canceling software standby mode, in order to ensure the PLL settling time.

**Figure 4.4 Example of External Clock Connection**

## 4.7 Oscillation Stop Detection

The CPG detects a stop in the clock input if any system abnormality halts the clock supply.

When no change has been detected in the EXTAL input for a certain period, the OSCSTOP bit in OSCCR is set to 1 and this state is retained until a power-on reset is input through the  $\overline{\text{RES}}$  pin is canceled. If the OSCERS bit is 1 at this time, an oscillation stop detection flag signal is output through the  $\overline{\text{WDTOVF}}$  pin. In addition, the high-current ports (multiplexed pins to which the TIOC3B, TIOC3D, and TIOC4A to TIOC4D signals in the MTU2, the TIOC3BS, TIOC3DS, and TIOC4AS to TIOC4DS in the MTU2S are assigned) can be placed in high-impedance state regardless of settings of the OSCERS bit and PFC.

Even in software standby mode, these pins can be placed in high-impedance state. For details, refer to appendix A, Pin States. Under an abnormal condition where oscillation stops while the LSI is not in software standby mode, LSI operations other than the oscillation stop detection function become unpredictable. In this case, even after oscillation is restarted, LSI operations including the above high-current pins become unpredictable.

Even while no change is detected in the EXTAL input, the PLL circuit in this LSI continues oscillating at a frequency range from 100 kHz to 10 MHz (depending on the temperature and operating voltage).

## 4.8 USB Operating Clock (48 MHz)

Connection of a ceramic resonator for USB, input of an external 48-MHz clock signal, and selection of the internal CPG are available as methods for supplying the USB operating clock.

### 4.8.1 Connecting a Ceramic Resonator

Figure 4.5 shows an example of the connections for a ceramic resonator.

**Figure 4.5 Example of Connecting a Ceramic Resonator**

4.8.2 Input of an External 48-MHz Clock Signal

Figure 4.6 shows an example of the connections for input of an external 48-MHz clock signal. The USBXTAL pin must be left open.

Figure 4.6 Example of Connecting an External 48-MHz Clock

Table 4.7 shows the input conditions for the external 48-MHz clock.

Table 4.7 Input Conditions for the External 48-MHz Clock

| Item                         | Symbol     | Min.  | Max.  | Unit | Reference Figure |
|------------------------------|------------|-------|-------|------|------------------|
| Frequency (48 MHz)           | $t_{FREQ}$ | 47.88 | 48.12 | MHz  | Figure 4.7       |
| Clock rise time              | $t_{R48}$  | —     | 3     | ns   |                  |
| Clock fall time              | $t_{F48}$  | —     | 3     | ns   |                  |
| Duty ( $t_{HIGH}/t_{FREQ}$ ) | $t_{DUTY}$ | 40    | 60    | %    |                  |

Figure 4.7 Input Timing of External 48-MHz Clock

### 4.8.3 Handling of pins when a Ceramic Resonator is not Connected (the Internal CPG is Selected or the USB is Not in Use)

When a ceramic resonator is not connected, connect the USBEXTAL pin to ground (Vss) and leave the USBXTAL pin open-circuit as shown in figure 4.8. Possible clock frequencies for input to EXTAL are fixed to 12 MHz. We recommend a 4-layer circuit board.

**Figure 4.8 Handling of Pins when a Ceramic Resonator is not Connected**

## 4.9 Notes on Board Design

### 4.9.1 Note on Using an External Crystal Resonator

Place the crystal resonator and capacitors CL1 and CL2 as close to the XTAL and EXTAL pins as possible. In addition, to minimize induction and thus obtain oscillation at the correct frequency, the capacitors to be attached to the resonator must be grounded to the same ground. Do not bring wiring patterns close to these components.

**Figure 4.9 Note on Using a Crystal Resonator**

A circuitry shown in figure 4.10 is recommended as an external circuitry around the PLL.  $PLL V_{CC}$ ,  $PLL V_{SS}$ ,  $V_{CL}$ , and  $V_{SS}$  must be separated from the board power supply source to avoid an influence from power supply noise. Be sure to insert bypass capacitors CB and CPB close to the  $V_{CL}$  and  $V_{SS}$  pins. We recommend a 4-layer circuit board so that stable power-supply and ground levels are supplied to the LSI.

**Figure 4.10 Recommended External Circuitry around PLL**

## Section 5 Exception Handling

### 5.1 Overview

#### 5.1.1 Types of Exception Handling and Priority

Exception handling is started by sources, such as resets, address errors, register bank errors, interrupts, and instructions. Table 5.1 shows their priorities. When several exception handling sources occur at once, they are processed according to the priority shown.

**Table 5.1 Types of Exception Handling and Priority Order**

| Type                | Exception Handling                               | Priority                                                                             |
|---------------------|--------------------------------------------------|--------------------------------------------------------------------------------------|
| Reset               | Power-on reset                                   |  |
|                     | Manual reset                                     |                                                                                      |
| Address error       | CPU address error                                |                                                                                      |
|                     | DMAC address error                               |                                                                                      |
| Instruction         | FPU exception                                    |                                                                                      |
|                     | Integer division exception (division by zero)    |                                                                                      |
|                     | Integer division exception (overflow)            |                                                                                      |
| Register bank error | Bank underflow                                   |                                                                                      |
|                     | Bank overflow                                    |                                                                                      |
| Interrupt           | NMI                                              |                                                                                      |
|                     | User break                                       |                                                                                      |
|                     | H-UDI                                            |                                                                                      |
|                     | IRQ                                              |                                                                                      |
|                     | Memory error (flash memory, data flash)          |                                                                                      |

|             | Slot illegal instructions (undefined code placed directly after a delayed branch instruction* <sup>1</sup> , instructions that rewrite the PC* <sup>2</sup> , 32-bit instructions* <sup>3</sup> , RESBANK instruction, DIVS instruction, and DIVU instruction) |                                                          |

Notes: 1. Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF.

2. Instructions that rewrite the PC: JMP, JSR, BRA, BSR, RTS, RTE, BT, BF, TRAPA, BF/S, BT/S, BSRF, BRAF, JSR/N, RTV/N.

3. 32-bit instructions: BAND.B, BANDNOT.B, BCLR.B, BLD.B, BLDNOT.B, BOR.B, BORNOT.B, BSET.B, BST.B, BXOR.B, FMOV.S@disp12, FMOV.D@disp12, MOV.B@disp12, MOV.W@disp12, MOV.L@disp12, MOVI20, MOVI20S, MOVU.B, MOVU.W.

### 5.1.2 Exception Handling Operations

The exception handling sources are detected and begin processing according to the timing shown in table 5.2.

**Table 5.2 Timing of Exception Source Detection and Start of Exception Handling**

| Exception           | Source                                | Timing of Source Detection and Start of Handling                                                                                                                                                                                                                                                           |
|---------------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reset               | Power-on reset                        | Starts when the $\overline{\text{RES}}$ pin changes from low to high, when the H-UDI reset negate command is set after the H-UDI reset assert command has been set, or when the WDT overflows.                                                                                                             |
|                     | Manual reset                          | Starts when the $\overline{\text{MRES}}$ pin changes from low to high or when the WDT overflows.                                                                                                                                                                                                           |
| Address error       |                                       | Detected when instruction is decoded and starts when the previous executing instruction finishes executing.                                                                                                                                                                                                |
| Interrupts          |                                       | Detected when instruction is decoded and starts when the previous executing instruction finishes executing.                                                                                                                                                                                                |
| Register bank error | Bank underflow                        | Starts upon attempted execution of a RESBANK instruction when saving has not been performed to register banks.                                                                                                                                                                                             |
|                     | Bank overflow                         | In the state where saving has been performed to all register bank areas, starts when acceptance of register bank overflow exception has been set by the interrupt controller (the BOVE bit in IBNR of the INTC is 1) and an interrupt that uses a register bank has occurred and been accepted by the CPU. |
| Instructions        | Trap instruction                      | Starts from the execution of a TRAPA instruction.                                                                                                                                                                                                                                                          |
|                     | General illegal instructions          | Starts from the decoding of undefined code anytime except immediately after a delayed branch instruction (delay slot).                                                                                                                                                                                     |
|                     | Slot illegal instructions             | Starts from the decoding of undefined code placed immediately after a delayed branch instruction (delay slot), of instructions that rewrite the PC, of 32-bit instructions, of the RESBANK instruction, of the DIVS instruction, or of the DIVU instruction.                                               |
|                     | Integer division instructions         | Starts when detecting division-by-zero exception or overflow exception caused by division of the negative maximum value (H'80000000) by $-1$ .                                                                                                                                                             |
|                     | Floating point operation instructions | Starts when detecting invalid operation exception defined by IEEE standard 754, division-by-zero exception, overflow, underflow, or inexact exception.<br><br>Also starts when qNAN or $\pm\infty$ is input to the source for a floating point operation instruction when the QIS bit in FPSCR is set.     |

When exception handling starts, the CPU operates as follows:

### **(1) Exception Handling Triggered by Reset**

The initial values of the program counter (PC) and stack pointer (SP) are fetched from the exception handling vector table (PC and SP are respectively the H'00000000 and H'00000004 addresses for power-on resets and the H'00000008 and H'0000000C addresses for manual resets). See section 5.1.3, Exception Handling Vector Table, for more information. The vector base register (VBR) is then initialized to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the interrupt controller (INTC) is also initialized to 0. The program begins running from the PC address fetched from the exception handling vector table.

### **(2) Exception Handling Triggered by Address Errors, Register Bank Errors, Interrupts, and Instructions**

SR and PC are saved to the stack indicated by R15. In the case of interrupt exception handling other than NMI or UBC with usage of the register banks enabled, general registers R0 to R14, control register GBR, system registers MACH, MACL, and PR, and the vector table address offset of the interrupt exception handling to be executed are saved to the register banks. In the case of exception handling due to an address error, register bank error, NMI interrupt, UBC interrupt, or instruction, saving to a register bank is not performed. When saving is performed to all register banks, automatic saving to the stack is performed instead of register bank saving. In this case, an interrupt controller setting must have been made so that register bank overflow exceptions are not accepted (the BOVE bit in IBNR of the INTC is 0). If a setting to accept register bank overflow exceptions has been made (the BOVE bit in IBNR of the INTC is 1), register bank overflow exception will be generated. In the case of interrupt exception handling, the interrupt priority level is written to the I3 to I0 bits in SR. In the case of exception handling due to an address error or instruction, the I3 to I0 bits are not affected. The start address is then fetched from the exception handling vector table and the program begins running from that address.

### 5.1.3 Exception Handling Vector Table

Before exception handling begins running, the exception handling vector table must be set in memory. The exception handling vector table stores the start addresses of exception service routines. (The reset exception handling table holds the initial values of PC and SP.)

All exception sources are given different vector numbers and vector table address offsets, from which the vector table addresses are calculated. During exception handling, the start addresses of the exception service routines are fetched from the exception handling vector table, which is indicated by this vector table address.

Table 5.3 shows the vector numbers and vector table address offsets. Table 5.4 shows how vector table addresses are calculated.

**Table 5.3 Exception Handling Vector Table**

| Exception Sources           |            | Vector Numbers | Vector Table Address Offset |
|-----------------------------|------------|----------------|-----------------------------|
| Power-on reset              | PC         | 0              | H'00000000 to H'00000003    |
|                             | SP         | 1              | H'00000004 to H'00000007    |
| Manual reset                | PC         | 2              | H'00000008 to H'0000000B    |
|                             | SP         | 3              | H'0000000C to H'0000000F    |
| General illegal instruction |            | 4              | H'00000010 to H'00000013    |
| (Reserved by system)        |            | 5              | H'00000014 to H'00000017    |
| Slot illegal instruction    |            | 6              | H'00000018 to H'0000001B    |
| (Reserved by system)        |            | 7              | H'0000001C to H'0000001F    |
|                             |            | 8              | H'00000020 to H'00000023    |
| CPU address error           |            | 9              | H'00000024 to H'00000027    |
| DMAC address error          |            | 10             | H'00000028 to H'0000002B    |
| Interrupts                  | NMI        | 11             | H'0000002C to H'0000002F    |
|                             | User break | 12             | H'00000030 to H'00000033    |
| FPU exception               |            | 13             | H'00000034 to H'00000037    |
| H-UDI                       |            | 14             | H'00000038 to H'0000003B    |
| Bank overflow               |            | 15             | H'0000003C to H'0000003F    |
| Bank underflow              |            | 16             | H'00000040 to H'00000043    |

| Exception Sources                                                | Vector Numbers | Vector Table Address Offset |
|------------------------------------------------------------------|----------------|-----------------------------|
| Integer division exception (division by zero)                    | 17             | H'00000044 to H'00000047    |
| Integer division exception (overflow)                            | 18             | H'00000048 to H'0000004B    |
| (Reserved by system)                                             | 19             | H'0000004C to H'0000004F    |
|                                                                  | :              | :                           |
|                                                                  | 31             | H'0000007C to H'0000007F    |
| Trap instruction (user vector)                                   | 32             | H'00000080 to H'00000083    |
|                                                                  | :              | :                           |
|                                                                  | 63             | H'000000FC to H'000000FF    |
| External interrupts (IRQ), on-chip peripheral module interrupts* | 64             | H'00000100 to H'00000103    |
|                                                                  | :              | :                           |
|                                                                  | 511            | H'000007FC to H'000007FF    |

Note: \* The vector numbers and vector table address offsets for each external interrupt and on-chip peripheral module interrupt are given in table 6.4 in section 6, Interrupt Controller (INTC).

**Table 5.4 Calculating Exception Handling Vector Table Addresses**

| Exception Source                                               | Vector Table Address Calculation                                                          |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| Resets                                                         | Vector table address = (vector table address offset)<br>= (vector number) × 4             |
| Address errors, register bank errors, interrupts, instructions | Vector table address = VBR + (vector table address offset)<br>= VBR + (vector number) × 4 |

Notes: 1. Vector table address offset: See table 5.3.  
2. Vector number: See table 5.3.

## 5.2 Resets

### 5.2.1 Types of Reset

A reset is the highest-priority exception handling source. There are two kinds of reset, power-on and manual. As shown in table 5.5, the CPU state is initialized in both a power-on reset and a manual reset. On-chip peripheral module registers are initialized by a power-on reset, but not by a manual reset.

**Table 5.5 Exception Source Detection and Exception Handling Start Timing**

| Type           | Conditions for Transition to Reset State            |                                              |                | Internal States |                                      |                             |
|----------------|-----------------------------------------------------|----------------------------------------------|----------------|-----------------|--------------------------------------|-----------------------------|
|                | $\overline{\text{RES}}$ or $\overline{\text{MRES}}$ | H-UDI Command                                | WDT Overflow   | CPU, FPU        | On-Chip Peripheral Modules, I/O Port | WRC SR of WDT, FRQCR of CPG |
| Power-on reset | Low                                                 | —                                            | —              | Initialized     | Initialized                          | Initialized                 |
|                | High                                                | H-UDI reset assert command is set            | —              | Initialized     | Initialized                          | Initialized                 |
|                | High                                                | Command other than H-UDI reset assert is set | Power-on reset | Initialized     | Initialized                          | Not initialized             |
| Manual reset   | Low                                                 | —                                            | —              | Initialized     | Not initialized*                     | Not initialized             |
|                | High                                                | —                                            | Manual reset   | Initialized     | Not initialized*                     | Not initialized             |

Note: \* The BN bit in IBNR of the INTC is initialized.

### 5.2.2 Power-On Reset

#### (1) Power-On Reset by Means of $\overline{\text{RES}}$ Pin

When the  $\overline{\text{RES}}$  pin is driven low, this LSI enters the power-on reset state. To reliably reset this LSI, the  $\overline{\text{RES}}$  pin should be kept at the low level for the duration of the oscillation settling time at power-on or when in software standby mode (when the clock is halted), or at least  $20 t_{\text{cyc}}$  when the clock is running. In the power-on reset state, the internal state of the CPU and all the on-chip peripheral module registers are initialized. See appendix A, Pin States, for the status of individual pins during the power-on reset state.

In the power-on reset state, power-on reset exception handling starts when the  $\overline{\text{RES}}$  pin is first driven low for a fixed period and then returned to high. The CPU operates as follows:

1. The initial value (execution start address) of the program counter (PC) is fetched from the exception handling vector table.
2. The initial value of the stack pointer (SP) is fetched from the exception handling vector table.
3. The vector base register (VBR) is cleared to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the INTC is also initialized to 0.
4. The values fetched from the exception handling vector table are set in the PC and SP, and the program begins executing.

Be certain to always perform power-on reset processing when turning the system power on.

#### (2) Power-On Reset by Means of H-UDI Reset Assert Command

When the H-UDI reset assert command is set, this LSI enters the power-on reset state. Power-on reset by means of an H-UDI reset assert command is equivalent to power-on reset by means of the  $\overline{\text{RES}}$  pin. Setting the H-UDI reset negate command cancels the power-on reset state. The time required between an H-UDI reset assert command and H-UDI reset negate command is the same as the time to keep the  $\overline{\text{RES}}$  pin low to initiate a power-on reset. In the power-on reset state generated by an H-UDI reset assert command, setting the H-UDI reset negate command starts power-on reset exception handling. The CPU operates in the same way as when a power-on reset was caused by the  $\overline{\text{RES}}$  pin.

### (3) Power-On Reset Initiated by WDT

When a setting is made for a power-on reset to be generated in the WDT's watchdog timer mode, and WTCNT of the WDT overflows, this LSI enters the power-on reset state.

In this case, WRCSR of the WDT and FRQCR of the CPG are not initialized by the reset signal generated by the WDT.

If a reset caused by the  $\overline{\text{RES}}$  pin or the H-UDI reset assert command occurs simultaneously with a reset caused by WDT overflow, the reset caused by the  $\overline{\text{RES}}$  pin or the H-UDI reset assert command has priority, and the WOVF bit in WRCSR is cleared to 0. When power-on reset exception processing is started by the WDT, the CPU operates in the same way as when a power-on reset was caused by the  $\overline{\text{RES}}$  pin.

## 5.2.3 Manual Reset

### (1) Manual Reset by Means of $\overline{\text{MRES}}$ Pin

When the  $\overline{\text{MRES}}$  pin is driven low, this LSI enters the manual reset state. To reset this LSI without fail, the  $\overline{\text{MRES}}$  pin should be kept at the low level for at least  $20 t_{\text{cyc}}$ . In the manual reset state, the CPU's internal state is initialized, but all the on-chip peripheral module registers are not initialized. In the manual reset state, manual reset exception handling starts when the  $\overline{\text{MRES}}$  pin is first driven low for a fixed period and then returned to high. The CPU operates as follows:

1. The initial value (execution start address) of the program counter (PC) is fetched from the exception handling vector table.
2. The initial value of the stack pointer (SP) is fetched from the exception handling vector table.
3. The vector base register (VBR) is cleared to H'00000000, the interrupt mask level bits (I3 to I0) of the status register (SR) are initialized to H'F (B'1111), and the BO and CS bits are initialized. The BN bit in IBNR of the INTC is also initialized to 0.
4. The values fetched from the exception handling vector table are set in the PC and SP, and the program begins executing.

## (2) Manual Reset Initiated by WDT

When a setting is made for a manual reset to be generated in the WDT's watchdog timer mode, and WTCNT of the WDT overflows, this LSI enters the manual reset state.

When manual reset exception processing is started by the WDT, the CPU operates in the same way as when a manual reset was caused by the  $\overline{\text{MRES}}$  pin.

When a manual reset is generated, the bus cycle is retained, but if a manual reset occurs while the bus is released or during DMAC burst transfer, manual reset exception handling will be deferred until the CPU acquires the bus.

## 5.3 Address Errors

### 5.3.1 Address Error Sources

Address errors occur when instructions are fetched or data read or written, as shown in table 5.6.

**Table 5.6 Bus Cycles and Address Errors**

| <b>Bus Cycle</b>  |                          |                                                                                                                        |                       |
|-------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------|-----------------------|
| <b>Type</b>       | <b>Bus Master</b>        | <b>Bus Cycle Description</b>                                                                                           | <b>Address Errors</b> |
| Instruction fetch | CPU                      | Instruction fetched from even address                                                                                  | None (normal)         |
|                   |                          | Instruction fetched from odd address                                                                                   | Address error occurs  |
|                   |                          | Instruction fetched from other than on-chip peripheral module space* or H'F0000000 to H'F5FFFFFF in on-chip RAM space* | None (normal)         |
|                   |                          | Instruction fetched from on-chip peripheral module space* or H'F0000000 to H'F5FFFFFF in on-chip RAM space*            | Address error occurs  |
|                   |                          | Instruction fetched from external memory space in single-chip mode                                                     | Address error occurs  |
| Data read/write   | CPU, DMAC, DTC or E-DMAC | Word data accessed from even address                                                                                   | None (normal)         |
|                   |                          | Word data accessed from odd address                                                                                    | Address error occurs  |
|                   |                          | Longword data accessed from a longword boundary                                                                        | None (normal)         |
|                   |                          | Longword data accessed from other than a long-word boundary                                                            | Address error occurs  |
|                   |                          | Byte or word data accessed in on-chip peripheral module space*                                                         | None (normal)         |
|                   |                          | Double longword data accessed from a double longword boundary                                                          | None (normal)         |
|                   |                          | Double Longword data accessed from other than a double longword boundary                                               | Address error occurs  |

| <b>Bus Cycle</b> |                          |                                                                   |                       |
|------------------|--------------------------|-------------------------------------------------------------------|-----------------------|
| <b>Type</b>      | <b>Bus Master</b>        | <b>Bus Cycle Description</b>                                      | <b>Address Errors</b> |
| Data read/write  | CPU, DMAC, DTC or E-DMAC | Longword data accessed in 16-bit on-chip peripheral module space* | None (normal)         |
|                  |                          | Longword data accessed in 8-bit on-chip peripheral module space*  | None (normal)         |
|                  |                          | External memory space accessed when in single chip mode           | Address error occurs  |

Note: \* See section 9, Bus State Controller (BSC), for details of the on-chip peripheral module space and on-chip RAM space.

### 5.3.2 Address Error Exception Handling

When an address error occurs, the bus cycle in which the address error occurred ends\*. When the executing instruction then finishes, address error exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the address error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

Note: \* In the case of an address error caused by instruction fetching when data is read or written, if the bus cycle on which the address error occurred is not completed by the end of the operations described above operation 3, the CPU will recommence address error exception processing until the end of that bus cycle.

## 5.4 Register Bank Errors

### 5.4.1 Register Bank Error Sources

#### (1) Bank Overflow

In the state where saving has already been performed to all register bank areas, bank overflow occurs when acceptance of register bank overflow exception has been set by the interrupt controller (the BOVE bit in IBNR of the INTC is set to 1) and an interrupt that uses a register bank has occurred and been accepted by the CPU.

#### (2) Bank Underflow

Bank underflow occurs when an attempt is made to execute a RESBANK instruction while saving has not been performed to register banks.

### 5.4.2 Register Bank Error Exception Handling

When a register bank error occurs, register bank error exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the register bank error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction for a bank overflow, and the start address of the executed RESBANK instruction for a bank underflow.

To prevent multiple interrupts from occurring at a bank overflow, the interrupt priority level that caused the bank overflow is written to the interrupt mask level bits (I3 to I0) of the status register (SR).

4. After jumping to the address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

## 5.5 Interrupts

### 5.5.1 Interrupt Sources

Table 5.7 shows the sources that start up interrupt exception handling. These are divided into NMI, user breaks, H-UDI, IRQ, memory errors, and on-chip peripheral modules.

**Table 5.7 Interrupt Sources**

| Type                      | Request Source                                  | Number of Sources |
|---------------------------|-------------------------------------------------|-------------------|
| NMI                       | NMI pin (external input)                        | 1                 |
| User break                | User break controller (UBC)                     | 1                 |
| H-UDI                     | User debugging interface (H-UDI)                | 1                 |
| IRQ                       | IRQ0 to IRQ7 pins (external input)              | 8                 |
| Memory error              | Flash memory (ROM), data flash (FLD)            | 1                 |
| On-chip peripheral module | A/D converter (ADC)                             | 2                 |
|                           | Controller area network (RCAN-ET)               | 4                 |
|                           | Direct memory access controller (DMAC)          | 16                |
|                           | Compare match timer (CMT)                       | 2                 |
|                           | Bus state controller (BSC)                      | 1                 |
|                           | Watchdog timer (WDT)                            | 1                 |
|                           | Ethernet controller (Ether-C, E-DMAC)           | 1                 |
|                           | USB function module (USB)                       | 6                 |
|                           | Multi-function timer pulse unit 2 (MTU2)        | 28                |
|                           | Multi-function timer pulse unit 2S (MTU2S)      | 13                |
|                           | Port output enable 2 (POE2)                     | 3                 |
|                           | I <sup>2</sup> C bus interface 3 (IIC3)         | 5                 |
|                           | Renesas serial peripheral interface (RSPI)      | 3                 |
|                           | Serial communication interface (SCI)            | 16                |
|                           | Serial communication interface with FIFO (SCIF) | 4                 |

Each interrupt source is allocated a different vector number and vector table offset. See table 6.4 in section 6, Interrupt Controller (INTC), for more information on vector numbers and vector table address offsets.

### 5.5.2 Interrupt Priority Level

The interrupt priority order is predetermined. When multiple interrupts occur simultaneously (overlap), the interrupt controller (INTC) determines their relative priorities and starts processing according to the results.

The priority order of interrupts is expressed as priority levels 0 to 16, with priority 0 the lowest and priority 16 the highest. The NMI interrupt has priority 16 and cannot be masked, so it is always accepted. The user break interrupt and H-UDI interrupt priority level is 15. Priority levels of IRQ interrupts, and on-chip peripheral module interrupts can be set freely using the interrupt priority registers 01, 02, and 05 to 19 (IPR01, IPR02, and IPR05 to IPR19) of the INTC as shown in table 5.8. The priority levels that can be set are 0 to 15. Level 16 cannot be set. See section 6.3.1, Interrupt Priority Registers 01, 02, 05 to 19 (IPR01, IPR02, IPR05 to IPR19), for details of IPR01, IPR02, and IPR05 to IPR19.

**Table 5.8 Interrupt Priority Order**

| Type                      | Priority Level | Comment                                      |
|---------------------------|----------------|----------------------------------------------|
| NMI                       | 16             | Fixed priority level. Cannot be masked.      |
| User break                | 15             | Fixed priority level.                        |
| H-UDI                     | 15             | Fixed priority level.                        |
| IRQ                       | 0 to 15        | Set with interrupt priority registers (IPR). |
| On-chip peripheral module |                |                                              |
| Memory error              | 15             | Fixed priority level.                        |

### 5.5.3 Interrupt Exception Handling

When an interrupt occurs, its priority level is ascertained by the interrupt controller (INTC). NMI is always accepted, but other interrupts are only accepted if they have a priority level higher than the priority level set in the interrupt mask level bits (I3 to I0) of the status register (SR).

When an interrupt is accepted, interrupt exception handling begins. In interrupt exception handling, the CPU fetches the exception service routine start address which corresponds to the accepted interrupt from the exception handling vector table, and saves SR and the program counter (PC) to the stack. In the case of interrupt exception handling other than NMI or UBC with usage of the register banks enabled, general registers R0 to R14, control register GBR, system registers MACH, MACL, and PR, and the vector table address offset of the interrupt exception handling to be executed are saved in the register banks. In the case of exception handling due to an address error, NMI interrupt, UBC interrupt, or instruction, saving is not performed to the register banks. If saving has been performed to all register banks (0 to 14), automatic saving to the stack is performed instead of register bank saving. In this case, an interrupt controller setting must have been made so that register bank overflow exceptions are not accepted (the BOVE bit in IBNR of the INTC is 0). If a setting to accept register bank overflow exceptions has been made (the BOVE bit in IBNR of the INTC is 1), register bank overflow exception occurs. Next, the priority level value of the accepted interrupt is written to the I3 to I0 bits in SR. For NMI, however, the priority level is 16, but the value set in the I3 to I0 bits is H'F (level 15). Then, after jumping to the start address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch. See section 6.6, Operation, for further details of interrupt exception handling.

## 5.6 Exceptions Triggered by Instructions

### 5.6.1 Types of Exceptions Triggered by Instructions

Exception handling can be triggered by trap instructions, slot illegal instructions, general illegal instructions, integer division exceptions, and floating-point operation instructions, as shown in table 5.9.

**Table 5.9 Types of Exceptions Triggered by Instructions**

| Type                                  | Source Instruction                                                                                                                                                                                    | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Trap instruction                      | TRAPA                                                                                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Slot illegal instructions             | Undefined code placed immediately after a delayed branch instruction (delay slot), instructions that rewrite the PC, 32-bit instructions, RESBANK instruction, DIVS instruction, and DIVU instruction | <p>Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF</p> <p>Instructions that rewrite the PC: JMP, JSR, BRA, BSR, RTS, RTE, BT, BF, TRAPA, BF/S, BT/S, BSRF, BRAF, JSR/N, RTV/N</p> <p>32-bit instructions: BAND.B, BANDNOT.B, BCLR.B, BLD.B, BLDNOT.B, BOR.B, BORNOT.B, BSET.B, BST.B, BXOR.B, MOV.B@disp12, MOV.W@disp12, FMOV.S@disp12, FMOV.D@disp12, MOV.L@disp12, MOVI20, MOVI20S, MOVU.B, MOVU.W.</p> |
| General illegal instructions          | Undefined code anywhere besides in a delay slot                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Integer division exceptions           | Division by zero                                                                                                                                                                                      | DIVU, DIVS                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                       | Negative maximum value $\div (-1)$                                                                                                                                                                    | DIVS                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Floating-point operation instructions | Starts when detecting invalid operation exception defined by IEEE754, division-by-zero exception, overflow, underflow, or inexact exception.                                                          | FADD, FSUB, FMUL, FDIV, FMAC, FCMP/EQ, FCMP/GT, FLOAT, FTRC, FCNVDS, FCNVSD, FSQRT                                                                                                                                                                                                                                                                                                                                                           |

### 5.6.2 Trap Instructions

When a TRAPA instruction is executed, trap instruction exception handling starts. The CPU operates as follows:

1. The exception service routine start address which corresponds to the vector number specified in the TRAPA instruction is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the TRAPA instruction.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.3 Slot Illegal Instructions

An instruction placed immediately after a delayed branch instruction is said to be placed in a delay slot. When the instruction placed in the delay slot is undefined code, an instruction that rewrites the PC, a 32-bit instruction, an RESBANK instruction, a DIVS instruction, or a DIVU instruction, slot illegal exception handling starts when such kind of instruction is decoded. The CPU operates as follows:

1. The exception service routine start address is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the jump address of the delayed branch instruction immediately before the undefined code, the instruction that rewrites the PC, the 32-bit instruction, the RESBANK instruction, the DIVS instruction, or the DIVU instruction.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.4 General Illegal Instructions

When undefined code placed anywhere other than immediately after a delayed branch instruction (i.e., in a delay slot) is decoded, general illegal instruction exception handling starts. The CPU handles general illegal instructions in the same way as slot illegal instructions. Unlike processing of slot illegal instructions, however, the program counter value stored is the start address of the undefined code.

### 5.6.5 Integer Division Instructions

When an integer division instruction performs division by zero or the result of integer division overflows, integer division instruction exception handling starts. The instructions that may become the source of division-by-zero exception are DIVU and DIVS. The only source instruction of overflow exception is DIVS, and overflow exception occurs only when the negative maximum value is divided by  $-1$ . The CPU operates as follows:

1. The exception service routine start address which corresponds to the integer division instruction exception that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the integer division instruction at which the exception occurred.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. The jump that occurs is not a delayed branch.

### 5.6.6 Floating Point Operation Instruction

An FPU exception is generated when the V, Z, O, U or I bit in the FPU enable field (Enable) of the floating point status/control register (FPSCR) is set. This indicates the occurrence of an invalid operation exception defined by the IEEE standard 754, a division-by-zero exception, overflow (in the case of an instruction for which this is possible), underflow (in the case of an instruction for which this is possible), or inexact exception (in the case of an instruction for which this is possible).

The instructions that may cause FPU exception are FADD, FSUB, FMUL, FDIV, FMAC, FCMP/EQ, FCMP/GT, FLOAT, FTRC, FCNVDS, FCNVSD, and FSQRT.

An FPU exception is generated only when the corresponding enable bit (Enable) is set. When the FPU detects an exception source, FPU operation is suspended and generation of the exception is reported to the CPU. When exception handling is started, the CPU operations are as follows.

1. The start address of the exception service routine corresponding to the FPU exception handling that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction.
4. After jumping to the address fetched from the exception handling vector table, program execution starts. This jump is not a delayed branch.

The FPU exception flag field (Flag) of FPSCR is always updated regardless of whether or not an FPU exception has been accepted, and remains set until explicitly cleared by the user through an instruction. The FPU exception source field (Cause) of FPSCR changes each time a floating-point operation instruction is executed.

When the V bit in the FPU exception enable field (Enable) of FPSCR is set and the QIS bit in FPSCR is also set, an FPU exception is generated when qNaN or  $\pm\infty$  is input to a floating point operation instruction source.

## 5.7 When Exception Sources Are Not Accepted

When an address error, register bank error (overflow), or interrupt is generated immediately after a delayed branch instruction, it is sometimes not accepted immediately but stored instead, as shown in table 5.10. When this happens, it will be accepted when an instruction that can accept the exception is decoded.

**Table 5.10 Exception Source Generation Immediately after Delayed Branch Instruction**

| Point of Occurrence                             | Exception Source |               |                                |              |
|-------------------------------------------------|------------------|---------------|--------------------------------|--------------|
|                                                 | Address Error    | FPU Exception | Register Bank Error (Overflow) | Interrupt    |
| Immediately after a delayed branch instruction* | Not accepted     | Not accepted  | Not accepted                   | Not accepted |

Note: \* Delayed branch instructions: JMP, JSR, BRA, BSR, RTS, RTE, BF/S, BT/S, BSRF, BRAF

## 5.8 Stack Status after Exception Handling Ends

The status of the stack after exception handling ends is as shown in table 5.11.

**Table 5.11 Stack Status After Exception Handling Ends**

| Exception Type                                  | Stack Status |                                                                                                            |
|-------------------------------------------------|--------------|------------------------------------------------------------------------------------------------------------|
| Address error                                   | SP →         | <div> <div>Address of instruction after executed instruction32 bits</div> <div>SR32 bits</div> </div>      |
| Interrupt                                       | SP →         | <div> <div>Address of instruction after executed instruction32 bits</div> <div>SR32 bits</div> </div>      |
| Register bank error (overflow)<br>FPU exception | SP →         | <div> <div>Address of instruction after executed instruction32 bits</div> <div>SR32 bits</div> </div>      |
| Register bank error (underflow)                 | SP →         | <div> <div>Start address of relevant RESBANK instruction32 bits</div> <div>SR32 bits</div> </div>          |
| Trap instruction                                | SP →         | <div> <div>Address of instruction after TRAPA instruction32 bits</div> <div>SR32 bits</div> </div>         |
| Slot illegal instruction                        | SP →         | <div> <div>Jump destination address of delayed branch instruction32 bits</div> <div>SR32 bits</div> </div> |

| Exception Type                                            | Stack Status                                                                                                                      |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| General illegal instruction                               | <div><div>SP →</div><div><div>Start address of general illegal instruction32 bits</div><div>SR32 bits</div></div></div>           |
| Integer division instruction (division by zero, overflow) | <div><div>SP →</div><div><div>Start address of relevant integer division instruction32 bits</div><div>SR32 bits</div></div></div> |

## 5.9 Usage Notes

### 5.9.1 Value of Stack Pointer (SP)

The value of the stack pointer must always be a multiple of four. If it is not, an address error will occur when the stack is accessed during exception handling.

### 5.9.2 Value of Vector Base Register (VBR)

The value of the vector base register must always be a multiple of four. If it is not, an address error will occur when the stack is accessed during exception handling.

### 5.9.3 Address Errors Caused by Stacking of Address Error Exception Handling

When the stack pointer is not a multiple of four, an address error will occur during stacking of the exception handling (interrupts, etc.) and address error exception handling will start up as soon as the first exception handling is ended. Address errors will then also occur in the stacking for this address error exception handling. To ensure that address error exception handling does not go into an endless loop, no address errors are accepted at that point. This allows program control to be shifted to the address error exception service routine and enables error processing.

When an address error occurs during exception handling stacking, the stacking bus cycle (write) is executed. During stacking of the status register (SR) and program counter (PC), the SP is decremented by 4 for both, so the value of SP will not be a multiple of four after the stacking either. The address value output during stacking is the SP value, so the address where the error occurred is itself output. This means the write data stacked will be undefined.

### 5.9.4 Note When Changing Interrupt Mask Level (IMASK) of Status Register (SR) in CPU

When enabling or disabling interrupts by modifying the interrupt mask level value of the CPU status register (SR) using an LDC or LDC.L instruction, there must be at least five instructions between the instruction to enable interrupts and the instruction to disable interrupts.

## Section 6 Interrupt Controller (INTC)

The interrupt controller (INTC) ascertains the priority of interrupt sources and controls interrupt requests to the CPU. The INTC registers set the order of priority of each interrupt, allowing the user to process interrupt requests according to the user-set priority.

### 6.1 Features

- 16 levels of interrupt priority can be set

By setting the 17 interrupt priority registers, the priority of IRQ interrupts and on-chip peripheral module interrupts can be selected from 16 levels for request sources.

- NMI noise canceler function

An NMI input-level bit indicates the NMI pin state. By reading this bit in the interrupt exception service routine, the pin state can be checked, enabling it to be used as the noise canceler function.

- Occurrence of interrupt can be reported externally ( $\overline{\text{IRQOUT}}$  pin)

For example, when this LSI has released the bus mastership, this LSI can inform the external bus master of occurrence of an on-chip peripheral module interrupt and request for the bus mastership.

- Register banks

This LSI has register banks that enable register saving and restoration required in the interrupt processing to be performed at high speed.

Figure 6.1 shows a block diagram of the INTC.

Figure 6.1 Block Diagram of INTC

## 6.2 Input/Output Pins

Table 6.1 shows the pin configuration of the INTC.

**Table 6.1 Pin Configuration**

| Pin Name                        | Symbol                     | I/O    | Function                                                  |
|---------------------------------|----------------------------|--------|-----------------------------------------------------------|
| Nonmaskable interrupt input pin | NMI                        | Input  | Input of nonmaskable interrupt request signal             |
| Interrupt request input pins    | IRQ7 to IRQ0               | Input  | Input of maskable interrupt request signals               |
| Interrupt request output pin    | $\overline{\text{IRQOUT}}$ | Output | Output of signal to report occurrence of interrupt source |

## 6.3 Register Descriptions

The INTC has the following registers. These registers are used to set the interrupt priorities and control detection of the external interrupt input signal.

**Table 6.2 Register Configuration**

| Register Name                               | Abbreviation | R/W                 | Initial Value  | Address    | Access Size |
|---------------------------------------------|--------------|---------------------|----------------|------------|-------------|
| Interrupt control register 0                | ICR0         | R/W                 | * <sup>1</sup> | H'FFFE0800 | 16, 32      |
| Interrupt control register 1                | ICR1         | R/W                 | H'0000         | H'FFFE0802 | 16          |
| IRQ interrupt request register              | IRQRR        | R/(W)* <sup>2</sup> | H'0000         | H'FFFE0806 | 16          |
| Bank control register                       | IBCR         | R/W                 | H'0000         | H'FFFE080C | 16, 32      |
| Bank number register                        | IBNR         | R/W                 | H'0000         | H'FFFE080E | 16          |
| Interrupt priority register 01              | IPR01        | R/W                 | H'0000         | H'FFFE0818 | 16, 32      |
| Interrupt priority register 02              | IPR02        | R/W                 | H'0000         | H'FFFE081A | 16          |
| Interrupt priority register 05              | IPR05        | R/W                 | H'0000         | H'FFFE0820 | 16          |
| Interrupt priority register 06              | IPR06        | R/W                 | H'0000         | H'FFFE0C00 | 16, 32      |
| Interrupt priority register 07              | IPR07        | R/W                 | H'0000         | H'FFFE0C02 | 16          |
| Interrupt priority register 08              | IPR08        | R/W                 | H'0000         | H'FFFE0C04 | 16, 32      |
| Interrupt priority register 09              | IPR09        | R/W                 | H'0000         | H'FFFE0C06 | 16          |
| Interrupt priority register 10              | IPR10        | R/W                 | H'0000         | H'FFFE0C08 | 16, 32      |
| Interrupt priority register 11              | IPR11        | R/W                 | H'0000         | H'FFFE0C0A | 16          |
| Interrupt priority register 12              | IPR12        | R/W                 | H'0000         | H'FFFE0C0C | 16, 32      |
| Interrupt priority register 13              | IPR13        | R/W                 | H'0000         | H'FFFE0C0E | 16          |
| Interrupt priority register 14              | IPR14        | R/W                 | H'0000         | H'FFFE0C10 | 16, 32      |
| Interrupt priority register 15              | IPR15        | R/W                 | H'0000         | H'FFFE0C12 | 16          |
| Interrupt priority register 16              | IPR16        | R/W                 | H'0000         | H'FFFE0C14 | 16, 32      |
| Interrupt priority register 17              | IPR17        | R/W                 | H'0000         | H'FFFE0C16 | 16          |
| Interrupt priority register 18              | IPR18        | R/W                 | H'0000         | H'FFFE0C18 | 16, 32      |
| Interrupt priority register 19              | IPR19        | R/W                 | H'0000         | H'FFFE0C1A | 16          |
| USB-DTC transfer interrupt request register | USDTESTR     | R/(W)* <sup>2</sup> | H'0000         | H'FFFE0C50 | 16          |

Notes: Two access cycles are needed for word access, and four access cycles for longword access.

1. When the NMI pin is high, becomes H'8000; when low, becomes H'0000.

2. Only 0 can be written after reading 1, to clear the flag.

### 6.3.1 Interrupt Priority Registers 01, 02, 05 to 19 (IPR01, IPR02, IPR05 to IPR19)

IPR01, IPR02, and IPR05 to IPR19 are 16-bit readable/writable registers in which priority levels from 0 to 15 are set for IRQ interrupts and on-chip peripheral module interrupts. Table 6.3 shows the correspondence between the interrupt request sources and the bits in IPR01, IPR02, and IPR05 to IPR19.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

| Interrupt priority register 16 | SCI0                                        | SCI1                                         | SCI2                                        | Reserved                                     |
| Interrupt priority register 17 | RSPI                                        | SCI4                                         | Reserved                                    | Reserved                                     |
| Interrupt priority register 18 | USB<br>(USI0, USI1)                         | RCAN-ET                                      | EP1-FIFO full DTC transfer end<br>(USBRX10) | EP2-FIFO empty DTC transfer end<br>(USBTX10) |
| Interrupt priority register 19 | EP4-FIFO full DTC transfer end<br>(USBRX11) | EP5-FIFO empty DTC transfer end<br>(USBTX11) | EtherC, E-DMAC<br>(EINT0)                   | Reserved                                     |

As shown in table 6.3, by setting the 4-bit groups (bits 15 to 12, bits 11 to 8, bits 7 to 4, and bits 3 to 0) with values from H'0 (0000) to H'F (1111), the priority of each corresponding interrupt is set. Setting of H'0 means priority level 0 (the lowest level) and H'F means priority level 15 (the highest level).

IPR01, IPR02, and IPR05 to IPR19 are initialized to H'0000 by a power-on reset.

### 6.3.2 Interrupt Control Register 0 (ICR0)

ICR0 is a 16-bit register that sets the input signal detection mode for the external interrupt input pin NMI, and indicates the input level at the NMI pin.

ICR0 is initialized by a power-on reset.

|                |      |    |    |    |    |    |   |      |   |   |   |   |   |   |   |   |
|----------------|------|----|----|----|----|----|---|------|---|---|---|---|---|---|---|---|
| Bit:           | 15   | 14 | 13 | 12 | 11 | 10 | 9 | 8    | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

### 6.3.3 Interrupt Control Register 1 (ICR1)

ICR1 is a 16-bit register that specifies the detection mode for external interrupt input pins IRQ7 to IRQ0 individually: low level, falling edge, rising edge, or both edges.

ICR1 is initialized by a power-on reset.

|                |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |

[Legend]

n = 7 to 0

Note: When the detecting condition of the IRQn input is changed, the IRQnF flag in IRQRR is cleared to 0.

### 6.3.4 IRQ Interrupt Request Register (IRQRR)

IRQRR is a 16-bit register that indicates interrupt requests from external input pins IRQ7 to IRQ0. If edge detection is set for the IRQ7 to IRQ0 interrupts, writing 0 to the IRQ7F to IRQ0F bits after reading IRQ7F to IRQ0F = 1 cancels the retained interrupts.

IRQRR is initialized by a power-on reset.

### 6.3.5 Bank Control Register (IBCR)

IBCR is a 16-bit register that enables or disables use of register banks for each interrupt priority level.

IBCR is initialized to H'0000 by a power-on reset.

### 6.3.6 Bank Number Register (IBNR)

IBNR is a 16-bit register that enables or disables use of register banks and register bank overflow exception. IBNR also indicates the bank number to which saving is performed next through the bits BN3 to BN0.

IBNR is initialized to H'0000 by a power-on reset.

When an interrupt using register banks is accepted, saving is performed to the register bank indicated by these bits, and BN is incremented by 1. After BN is decremented by 1 due to execution of a RESBANK (restore from register bank) instruction, restoration from the register bank is performed. |

### 6.3.7 USB-DTC Transfer Interrupt Request Register (USDENDRR)

USDENDRR is a 16-bit register that indicates USB-DTC transfer end interrupt requests, which are on-chip peripheral module interrupts. Writing 0 to the RXF or TXF bit after reading RXF = 1 or TXF = 1 cancels the retained interrupt.

USDENDRR is initialized by a power-on reset.

## 6.4 Interrupt Sources

There are six types of interrupt sources: NMI, user break, H-UDI, IRQ, memory error, and on-chip peripheral modules. Each interrupt has a priority level (0 to 16), with 0 the lowest and 16 the highest. When set to level 0, that interrupt is masked at all times.

### 6.4.1 NMI Interrupt

The NMI interrupt has a priority level of 16 and is accepted at all times. NMI interrupt requests are edge-detected, and the NMI edge select bit (NMIE) in interrupt control register 0 (ICR0) selects whether the rising edge or falling edge is detected.

Though the priority level of the NMI interrupt is 16, the NMI interrupt exception handling sets the interrupt mask level bits (I3 to I0) in the status register (SR) to level 15.

### 6.4.2 User Break Interrupt

A user break interrupt which occurs when a break condition set in the user break controller (UBC) matches has a priority level of 15. The user break interrupt exception handling sets the I3 to I0 bits in SR to level 15. For user break interrupts, see section 7, User Break Controller (UBC).

### 6.4.3 H-UDI Interrupt

The user debugging interface (H-UDI) interrupt has a priority level of 15, and occurs at serial input of an H-UDI interrupt instruction. H-UDI interrupt requests are edge-detected and retained until they are accepted. The H-UDI interrupt exception handling sets the I3 to I0 bits in SR to level 15. For H-UDI interrupts, see section 31, User Debugging Interface (H-UDI).

#### 6.4.4 IRQ Interrupts

IRQ interrupts are input from pins IRQ7 to IRQ0. For the IRQ interrupts, low-level, falling-edge, rising-edge, or both-edge detection can be selected individually for each pin by the IRQ sense select bits (IRQ71S to IRQ01S and IRQ70S to IRQ00S) in interrupt control register 1 (ICR1). The priority level can be set individually in a range from 0 to 15 for each pin by interrupt priority registers 01 and 02 (IPR01 and IPR02).

When using low-level setting for IRQ interrupts, an interrupt request signal is sent to the INTC while the IRQ7 to IRQ0 pins are low. An interrupt request signal is stopped being sent to the INTC when the IRQ7 to IRQ0 pins are driven high. The status of the interrupt requests can be checked by reading the IRQ interrupt request bits (IRQ7F to IRQ0F) in the IRQ interrupt request register (IRQRR).

When using edge-sensing for IRQ interrupts, an interrupt request is detected due to change of the IRQ7 to IRQ0 pin states, and an interrupt request signal is sent to the INTC. The result of IRQ interrupt request detection is retained until that interrupt request is accepted. Whether IRQ interrupt requests have been detected or not can be checked by reading the IRQ7F to IRQ0F bits in IRQRR. Writing 0 to these bits after reading them as 1 clears the result of IRQ interrupt request detection.

The IRQ interrupt exception handling sets the I3 to I0 bits in SR to the priority level of the accepted IRQ interrupt. Satisfaction of the setting condition for an individual IRQnF bit leads to the bit being set regardless of the setting of the I3 to I0 bits in SR.

#### 6.4.5 Memory Error Interrupt

For details on the sources generating a memory error, see section 27, Flash Memory (ROM).

### 6.4.6 On-Chip Peripheral Module Interrupts

On-chip peripheral module interrupts are generated by the following on-chip peripheral modules:

- A/D converter (ADC)
- Controller area network (RCAN-ET)
- Direct memory access controller (DMAC)
- Compare match timer (CMT)
- Bus state controller (BSC)
- Watchdog timer (WDT)
- Ethernet Controller (EtherC, E-DMAC)
- USB function module (USB)
- Multi-function timer pulse unit 2 (MTU2)
- Multi-function timer pulse unit 2S (MTU2S)
- Port output enable 2 (POE2)
- I<sup>2</sup>C bus interface 3 (IIC3)
- Renesas serial peripheral interface (RSPI)
- Serial communication interface (SCI)
- Serial communication interface with FIFO (SCIF)

As every source is assigned a different interrupt vector, the source does not need to be identified in the exception service routine. A priority level in a range from 0 to 15 can be set for each module by interrupt priority registers 05 to 19 (IPR05 to IPR19). The on-chip peripheral module interrupt exception handling sets the I3 to I0 bits in SR to the priority level of the accepted on-chip peripheral module interrupt.

## 6.5 Interrupt Exception Handling Vector Table and Priority

Table 6.4 lists interrupt sources and their vector numbers, vector table address offsets, and interrupt priorities.

Each interrupt source is allocated a different vector number and vector table address offset. Vector table addresses are calculated from the vector numbers and vector table address offsets. In interrupt exception handling, the interrupt exception service routine start address is fetched from the vector table indicated by the vector table address. For details of calculation of the vector table address, see table 5.4 in section 5, Exception Handling.

The priorities of IRQ interrupts and on-chip peripheral module interrupts can be set freely between 0 and 15 for each pin or module by setting interrupt priority registers 01, 02, and 05 to 19 (IPR01, IPR02, and IPR05 to IPR19). However, if two or more interrupts specified by the same IPR among IPR05 to IPR19 occur, the priorities are defined as shown in the IPR setting unit internal priority of table 6.4, and the priorities cannot be changed. A power-on reset assigns priority level 0 to IRQ interrupts and on-chip peripheral module interrupts. If the same priority level is assigned to two or more interrupt sources and interrupts from those sources occur simultaneously, they are processed by the default priorities indicated in table 6.4.

### Table 6.4 Interrupt Exception Handling Vectors and Priorities

| Interrupt Vector        |      |        |                             |                                    |                         | IPR Setting Unit  |
|-------------------------|------|--------|-----------------------------|------------------------------------|-------------------------|-------------------|
| Interrupt Source Number |      | Vector | Vector Table Address Offset | Interrupt Priority (Initial Value) | Corresponding IPR (Bit) | Internal Priority |
|                         |      |        |                             |                                    |                         |                   |
| NMI                     |      | 11     | H'0000002C to H'0000002F    | 16                                 | —                       | —                 |
| UBC                     |      | 12     | H'00000030 to H'00000033    | 15                                 | —                       | —                 |
| H-UDI                   |      | 14     | H'00000038 to H'0000003B    | 15                                 | —                       | —                 |
| IRQ                     | IRQ0 | 64     | H'00000100 to H'00000103    | 0 to 15 (0)                        | IPR01 (15 to 12)        | —                 |
|                         | IRQ1 | 65     | H'00000104 to H'00000107    | 0 to 15 (0)                        | IPR01 (11 to 8)         | —                 |
|                         | IRQ2 | 66     | H'00000108 to H'0000010B    | 0 to 15 (0)                        | IPR01 (7 to 4)          | —                 |
|                         | IRQ3 | 67     | H'0000010C to H'0000010F    | 0 to 15 (0)                        | IPR01 (3 to 0)          | —                 |
|                         | IRQ4 | 68     | H'00000110 to H'00000113    | 0 to 15 (0)                        | IPR02 (15 to 12)        | —                 |
|                         | IRQ5 | 69     | H'00000114 to H'00000117    | 0 to 15 (0)                        | IPR02 (11 to 8)         | —                 |
|                         | IRQ6 | 70     | H'00000118 to H'0000011B    | 0 to 15 (0)                        | IPR02 (7 to 4)          | —                 |

   ## 6.6 Operation

### 6.6.1 Interrupt Operation Sequence

The sequence of interrupt operations is described below. Figure 6.2 shows the operation flow.

1. The interrupt request sources send interrupt request signals to the interrupt controller.
2. The interrupt controller selects the highest-priority interrupt from the interrupt requests sent, following the priority levels set in interrupt priority registers 01, 02, and 05 to 19 (IPR01, IPR02, and IPR05 to IPR19). Lower priority interrupts are ignored\*. If two of these interrupts have the same priority level or if multiple interrupts occur within a single IPR, the interrupt with the highest priority is selected, according to the default priority and IPR setting unit internal priority shown in table 6.4.
3. The priority level of the interrupt selected by the interrupt controller is compared with the interrupt level mask bits (I3 to I0) in the status register (SR) of the CPU. If the interrupt request priority level is equal to or less than the level set in bits I3 to I0, the interrupt request is ignored. If the interrupt request priority level is higher than the level in bits I3 to I0, the interrupt controller accepts the interrupt and sends an interrupt request signal to the CPU.
4. When the interrupt controller accepts an interrupt, a low level is output from the  $\overline{\text{IRQOUT}}$  pin.
5. The CPU detects the interrupt request sent from the interrupt controller when the CPU decodes the instruction to be executed. Instead of executing the decoded instruction, the CPU starts interrupt exception handling (figure 6.4).
6. The interrupt exception service routine start address is fetched from the exception handling vector table corresponding to the accepted interrupt.
7. The status register (SR) is saved onto the stack, and the priority level of the accepted interrupt is copied to bits I3 to I0 in SR.
8. The program counter (PC) is saved onto the stack.
9. The CPU jumps to the fetched interrupt exception service routine start address and starts executing the program. The jump that occurs is not a delayed branch.
10. A high level is output from the  $\overline{\text{IRQOUT}}$  pin. However, if the interrupt controller accepts an interrupt with a higher priority than the interrupt just being accepted, the  $\overline{\text{IRQOUT}}$  pin holds low level.

Notes: The interrupt source flag should be cleared in the interrupt handler. After clearing the interrupt source flag, "time from occurrence of interrupt request until interrupt controller identifies priority, compares it with mask bits in SR, and sends interrupt request signal to CPU" shown in table 6.5 is required before the interrupt source sent to the CPU is actually cancelled. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag after it has been cleared, and then execute an RTE instruction.

- \* Interrupt requests that are designated as edge-sensing are held pending until the interrupt requests are accepted. IRQ interrupts, however, can be cancelled by accessing the IRQ interrupt request register (IRQRR). For details, see section 6.4.4, IRQ Interrupts.

Interrupts held pending due to edge-sensing are cleared by a power-on reset.

Figure 6.2 Interrupt Operation Flow

## 6.6.2 Stack after Interrupt Exception Handling

Figure 6.3 shows the stack after interrupt exception handling.

**Figure 6.3 Stack after Interrupt Exception Handling**

## 6.7 Interrupt Response Time

Table 6.5 lists the interrupt response time, which is the time from the occurrence of an interrupt request until the interrupt exception handling starts and fetching of the first instruction in the exception service routine begins. The interrupt processing operations differ in the cases when banking is disabled, when banking is enabled without register bank overflow, and when banking is enabled with register bank overflow. Figures 6.4 and 6.5 show examples of pipeline operation when banking is disabled. Figures 6.6 and 6.7 show examples of pipeline operation when banking is enabled without register bank overflow. Figures 6.8 and 6.9 show examples of pipeline operation when banking is enabled with register bank overflow.

**Table 6.5 Interrupt Response Time**

| Number of States                                                                                                                                                                                            |                                                 |                          |                          |                 |                           |                          |                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|--------------------------|--------------------------|-----------------|---------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Item                                                                                                                                                                                                        |                                                 | NMI                      | UBC                      | H-UDI           | IRQ                       | Peripheral Module        | Remarks                                                                                                                                             |
| Time from occurrence of interrupt request until interrupt controller identifies priority, compares it with mask bits in SR, and sends interrupt request signal to CPU                                       |                                                 | 2 IcyC + 2 Bcyc + 1 PcyC | 3 IcyC                   | 2 IcyC + 1 PcyC | 2 IcyC + 3 Bcyc + 1 PcyC  | 2 IcyC + 1 Bcyc + 2 PcyC | Interrupts with the DTC activation sources                                                                                                          |
|                                                                                                                                                                                                             |                                                 |                          |                          |                 |                           | 2 IcyC + 1 Bcyc + 1 Bcyc | Interrupts without the DTC activation sources.                                                                                                      |
| Time from input of interrupt request signal to CPU until sequence currently being executed is completed, interrupt exception handling starts, and first instruction in exception service routine is fetched | No register banking                             | Min.                     | 3 IcyC + m1 + m2         |                 |                           |                          | Min. is when the interrupt wait time is zero.<br>Max. is when a higher-priority interrupt request has occurred during interrupt exception handling. |

Notes: m1 to m4 are the number of states needed for the following memory accesses.

m1: Vector address read (longword read)

m2: SR save (longword write)

m3: PC save (longword write)

m4: Banked registers (R0 to R14, GBR, MACH, MACL, and PR) are restored from the stack.

1. In the case that m1 = m2 = m3 = m4 = 1 lcy.
2. In the case that (I $\phi$ , B $\phi$ , P $\phi$ ) = (100 MHz, 50 MHz, 50 MHz).
3. In the case that (I $\phi$ , B $\phi$ , P $\phi$ ) = (200 MHz, 50 MHz, 50 MHz).

## 6.8 Register Banks

This LSI has fifteen register banks used to perform register saving and restoration required in the interrupt processing at high speed. Figure 6.10 shows the register bank configuration.

**Figure 6.10 Overview of Register Bank Configuration**

## 6.8.1 Banked Register and Input/Output of Banks

### (1) Banked Register

The contents of the general registers (R0 to R14), global base register (GBR), multiply and accumulate registers (MACH and MACL), and procedure register (PR), and the vector table address offset are banked.

### (2) Register Banks

This LSI has fifteen register banks, bank 0 to bank 14. Register banks are stacked in first-in last-out (FILO) sequence. Saving takes place in order, beginning from bank 0, and restoration takes place in the reverse order, beginning from the last bank saved to.

## 6.8.2 Bank Save and Restore Operations

### (1) Saving to Bank

Figure 6.11 shows register bank save operations. The following operations are performed when an interrupt for which usage of register banks is allowed is accepted by the CPU:

- Assume that the bank number bit value in the bank number register (IBNR), BN, is "i" before the interrupt is generated.
- The contents of registers R0 to R14, GBR, MACH, MACL, and PR, and the interrupt vector table address offset (VTO) of the accepted interrupt are saved in the bank indicated by BN, bank i.
- The BN value is incremented by 1.

**Figure 6.11 Bank Save Operations**

Figure 6.12 shows the timing for saving to a register bank. Saving to a register bank takes place between the start of interrupt exception handling and the start of fetching the first instruction in the interrupt exception service routine.

**Figure 6.12 Bank Save Timing**

## (2) Restoration from Bank

The RESBANK (restore from register bank) instruction is used to restore data saved in a register bank. After restoring data from the register banks with the RESBANK instruction at the end of the interrupt service routine, execute the RTE instruction to return from the exception handling.

### 6.8.3 Save and Restore Operations after Saving to All Banks

If an interrupt occurs and usage of the register banks is enabled for the interrupt accepted by the CPU in a state where saving has been performed to all register banks, automatic saving to the stack is performed instead of register bank saving if the BOVE bit in the bank number register (IBNR) is cleared to 0. If the BOVE bit in IBNR is set to 1, register bank overflow exception occurs and data is not saved to the stack.

Save and restore operations when using the stack are as follows:

#### (1) Saving to Stack

1. The status register (SR) and program counter (PC) are saved to the stack during interrupt exception handling.
2. The contents of the banked registers (R0 to R14, GBR, MACH, MACL, and PR) are saved to the stack. The registers are saved to the stack in the order of MACL, MACH, GBR, PR, R14, R13, ..., R1, and R0.
3. The register bank overflow bit (BO) in SR is set to 1.
4. The bank number bit (BN) value in the bank number register (IBNR) remains set to the maximum value of 15.

#### (2) Restoration from Stack

When the RESBANK (restore from register bank) instruction is executed with the register bank overflow bit (BO) in SR set to 1, the CPU operates as follows:

1. The contents of the banked registers (R0 to R14, GBR, MACH, MACL, and PR) are restored from the stack. The registers are restored from the stack in the order of R0, R1, ..., R13, R14, PR, GBR, MACH, and MACL.
2. The bank number bit (BN) value in the bank number register (IBNR) remains set to the maximum value of 15.

### 6.8.4 Register Bank Exception

There are two register bank exceptions (register bank errors): register bank overflow and register bank underflow.

#### (1) Register Bank Overflow

This exception occurs if, after data has been saved to all of the register banks, an interrupt for which register bank use is allowed is accepted by the CPU, and the BOVE bit in the bank number register (IBNR) is set to 1. In this case, the bank number bit (BN) value in the bank number register (IBNR) remains set to the bank count of 15 and saving is not performed to the register bank.

#### (2) Register Bank Underflow

This exception occurs if the RESBANK (restore from register bank) instruction is executed when no data has been saved to the register banks. In this case, the values of R0 to R14, GBR, MACH, MACL, and PR do not change. In addition, the bank number bit (BN) value in the bank number register (IBNR) remains set to 0.

### 6.8.5 Register Bank Error Exception Handling

When a register bank error occurs, register bank error exception handling starts. When this happens, the CPU operates as follows:

1. The exception service routine start address which corresponds to the register bank error that occurred is fetched from the exception handling vector table.
2. The status register (SR) is saved to the stack.
3. The program counter (PC) is saved to the stack. The PC value saved is the start address of the instruction to be executed after the last executed instruction for a register bank overflow, and the start address of the executed RESBANK instruction for a register bank underflow. To prevent multiple interrupts from occurring at a register bank overflow, the interrupt priority level that caused the register bank overflow is written to the interrupt mask level bits (I3 to I0) of the status register (SR).
4. Program execution starts from the exception service routine start address.

## 6.9 Data Transfer with Interrupt Request Signals

Interrupt request signals can be used to trigger the following data transfer.

- Only the DMAC is activated and no CPU interrupt occurs.
- Only the DTC is activated and a CPU interrupt may occur depending on the DTC setting.

Interrupt sources that are designated to activate the DMAC are masked without being input to the INTC. The mask condition is as follows:

$$\begin{aligned} \text{Mask condition} = & \text{DME} \bullet (\text{DE0} \bullet \text{interrupt source select 0} + \text{DE1} \bullet \text{interrupt source select 1} \\ & + \text{DE2} \bullet \text{interrupt source select 2} + \text{DE3} \bullet \text{interrupt source select 3} + \\ & \text{DE4} \bullet \text{interrupt source select 4} + \text{DE5} \bullet \text{interrupt source select 5} + \text{DE6} \\ & \bullet \text{interrupt source select 6} + \text{DE7} \bullet \text{interrupt source select 7}) \end{aligned}$$

Here, DME is bit 0 in DMAOR of the DMAC, and DE<sub>n</sub> (n = 0 to 7) is bit 0 in CHCR0 to CHCR7 of the DMAC. For details, see section 10, Direct Memory Access Controller (DMAC).

The INTC masks a CPU interrupt when the corresponding DTCE bit is 1. The DTCE clearing condition and interrupt source flag clearing condition are as follows:

$$\text{DTCE clearing condition} = \text{DTC transfer end} \bullet \text{DTCECLR}$$

$$\text{Interrupt source flag clearing condition} = \text{DTC transfer end} \bullet \overline{\text{DTCECLR}} + \text{DMAC transfer end}$$

$$\text{However, DTCECLR} = \text{DISEL} + \text{counter value of 0}$$

Figures 6.13 and 6.14 show block diagrams of interrupt control.

**Figure 6.13 Interrupt Control Block Diagram**

**Figure 6.14 Block Diagram of Controlling an On-Chip Peripheral Module Interrupt**

### **6.9.1 Handling Interrupt Request Signals as DTC Activating Sources and CPU Interrupt Sources but Not as DMAC Activating Sources**

1. Do not select DMAC activating sources or clear the DME bit to 0. If, DMAC activating sources are selected, clear the DE bit to 0 for the relevant channel of the DMAC.
2. Set both the corresponding DTCE bit and DISEL bit to 1 in the DTC.
3. Activating sources are applied to the DTC when interrupts occur.
4. The DTC clears the DTCE bit to 0 and sends interrupt requests to the CPU when starting data transfer. The DTC does not clear the activating sources.
5. The CPU clears the interrupt sources in the interrupt exception handling routine, and then confirms the transfer counter value. If the transfer counter value is not 0, the DTCE bit is set to 1 and the next data transfer enabled. If the transfer counter value is 0, the CPU performs the necessary termination processing in the interrupt exception handling routine.

### **6.9.2 Handling Interrupt Request Signals as DMAC Activating Sources but Not as CPU Interrupt Sources**

1. Select DMAC activating sources and set both the DE and DME bits to 1. This masks CPU interrupt sources regardless of the interrupt priority register and DTC register settings.
2. Activating sources are applied to the DMAC when interrupts occur.
3. The DMAC clears the activating sources when starting data transfer.

### **6.9.3 Handling Interrupt Request Signals as DTC Activating Sources but Not as CPU Interrupt Sources or DMAC Activating Sources**

1. Do not select DMAC activating sources or clear the DME bit to 0. If, DMAC activating sources are selected, clear the DE bit to 0 for the relevant channel of the DMAC.
2. Set the corresponding DTCE bit to 1 and clear the DISEL bit to 0 in the DTC.
3. Activating sources are applied to the DTC when interrupts occur.
4. The DTC clears the activating sources when starting data transfer. Interrupt requests are not sent to the CPU because the DTCE bit remains set to 1.
5. However, when the transfer counter value is 0, the DTCE bit is cleared to 0 and interrupt requests are sent to the CPU.
6. The CPU performs the necessary termination processing in the interrupt exception handling routine.

### 6.9.4 Handling Interrupt Request Signals as CPU Interrupt Sources but Not as DTC Activating Sources or DMAC Activating Sources

1. Do not select DMAC activating sources or clear the DME bit to 0. If, DMAC activating sources are selected, clear the DE bit to 0 for the relevant channel of the DMAC.
2. Clear the corresponding DTCE bit to 0 in the DTC.
3. Interrupt requests are sent to the CPU when interrupts occur.
4. The CPU clears the interrupt sources and performs the necessary termination processing in the interrupt exception handling routine.

## 6.10 Usage Notes

### 6.10.1 Timing to Clear an Interrupt Source

The interrupt source flags should be cleared in the interrupt exception service routine. After clearing the interrupt source flag, "time from occurrence of interrupt request until interrupt controller identifies priority, compares it with mask bits in SR, and sends interrupt request signal to CPU" shown in table 6.5 is required before the interrupt source sent to the CPU is actually cancelled. To ensure that an interrupt request that should have been cleared is not inadvertently accepted again, read the interrupt source flag after it has been cleared, and then execute an RTE instruction.

### 6.10.2 In Case the NMI Pin is not in Use

When the NMI pin is not in use, fix the pin to the high level by connecting the pin to  $V_{cc}Q$  via a resistor.

### 6.10.3 Negate Timing of $\overline{IRQOUT}$

When the interrupt controller accepts an interrupt request, a low-level signal is output from the  $\overline{IRQOUT}$  pin, and after jumping to the start address of the interrupt exception service routine, a high-level signal is output from the  $\overline{IRQOUT}$  pin.

However, in the case where an interrupt request is accepted by the interrupt controller and a low-level signal is output from the  $\overline{IRQOUT}$  pin, but the interrupt request is canceled before a jump is made to the start address of the interrupt exception service routine, a low-level signal will be output from the  $\overline{IRQOUT}$  pin until a jump is made to the start address of the interrupt exception service routine called by the next interrupt request.

#### 6.10.4 Notes on Canceling Software Standby Mode with an IRQx Interrupt Request

When canceling software standby mode using an IRQx interrupt request, change the IRQ sense select setting of ICRx in a state in which no IRQx interrupt requests are generated and clear the IRQxF flag in IRQRRx to 0 by the automatic clearing function of the IRQx interrupt processing.

If the IRQxF flag in the IRQ interrupt request register x (IRQRRx) is 1, changing the setting of the IRQ sense select bits in the interrupt control register x (ICRx) or clearing the IRQxF flag in IRQRRx to 0 will clear the relevant IRQx interrupt request but will not clear the software standby cancellation request.

## Section 7 User Break Controller (UBC)

The user break controller (UBC) provides functions that simplify program debugging. These functions make it easy to design an effective self-monitoring debugger, enabling the chip to debug programs without using an in-circuit emulator. Instruction fetch or data read/write (bus master (CPU, DMAC, or DTC) selection in the case of data read/write), data size, data contents, address value, and stop timing in the case of instruction fetch are break conditions that can be set in the UBC. Since this LSI uses a Harvard architecture, instruction fetch on the CPU bus (C bus) is performed by issuing bus cycles on the instruction fetch bus (F bus), and data access on the C bus is performed by issuing bus cycles on the memory access bus (M bus). The UBC monitors the C bus and internal bus (I bus).

### 7.1 Features

1. The following break comparison conditions can be set.
  - Number of break channels: four channels (channels 0 to 3)
  - User break can be requested as the independent condition on channels 0, 1, 2, and 3.
  - Address
    - Comparison of the 32-bit address is maskable in 1-bit units.
    - One of the three address buses (F address bus (FAB), M address bus (MAB), and I address bus (IAB)) can be selected.
  - Bus master when I bus is selected
    - Selection of CPU cycles, DMAC cycles, or DTC cycles
  - Bus cycle
    - Instruction fetch (only when C bus is selected) or data access
  - Read/write
  - Operand size
    - Byte, word, and longword
2. Exception handling routine for user-specified break conditions can be executed.
3. In an instruction fetch cycle, it can be selected whether PC breaks are set before or after an instruction is executed.
4. When a break condition is satisfied, a trigger signal is output from the  $\overline{\text{UBCTR}}\text{G}$  pin.

Figure 7.1 shows a block diagram of the UBC.

**Figure 7.1 Block Diagram of UBC**

## 7.2 Input/Output Pin

Table 7.1 shows the pin configuration of the UBC.

**Table 7.1 Pin Configuration**

| Pin Name    | Symbol | I/O    | Function                                                                                    |
|-------------|--------|--------|---------------------------------------------------------------------------------------------|
| UBC trigger | UBCTRG | Output | Indicates that a setting condition is satisfied on either channel 0, 1, 2, or 3 of the UBC. |

## 7.3 Register Descriptions

The UBC has the following registers.

**Table 7.2 Register Configuration**

| Channel | Register Name                 | Abbrevia-<br>tion | R/W | Initial Value | Address    | Access<br>Size |
|---------|-------------------------------|-------------------|-----|---------------|------------|----------------|
| 0       | Break address register_0      | BAR_0             | R/W | H'00000000    | H'FFFC0400 | 32             |
|         | Break address mask register_0 | BAMR_0            | R/W | H'00000000    | H'FFFC0404 | 32             |
|         | Break bus cycle register_0    | BBR_0             | R/W | H'0000        | H'FFFC04A0 | 16             |
| 1       | Break address register_1      | BAR_1             | R/W | H'00000000    | H'FFFC0410 | 32             |
|         | Break address mask register_1 | BAMR_1            | R/W | H'00000000    | H'FFFC0414 | 32             |
|         | Break bus cycle register_1    | BBR_1             | R/W | H'0000        | H'FFFC04B0 | 16             |
| 2       | Break address register_2      | BAR_2             | R/W | H'00000000    | H'FFFC0420 | 32             |
|         | Break address mask register_2 | BAMR_2            | R/W | H'00000000    | H'FFFC0424 | 32             |
|         | Break bus cycle register_2    | BBR_2             | R/W | H'0000        | H'FFFC04A4 | 16             |
| 3       | Break address register_3      | BAR_3             | R/W | H'00000000    | H'FFFC0430 | 32             |
|         | Break address mask register_3 | BAMR_3            | R/W | H'00000000    | H'FFFC0434 | 32             |
|         | Break bus cycle register_3    | BBR_3             | R/W | H'0000        | H'FFFC04B4 | 16             |
| Common  | Break control register        | BRCR              | R/W | H'00000000    | H'FFFC04C0 | 32             |

### 7.3.1 Break Address Register\_0 (BAR\_0)

BAR\_0 is a 32-bit readable/writable register. BAR\_0 specifies the address used as a break condition in channel 0. The control bits CD0\_1 and CD0\_0 in the break bus cycle register\_0 (BBR\_0) select one of the three address buses for a break condition of channel 0. BAR\_0 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

|                |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|----------------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
| Bit:           | 31     | 30     | 29     | 28     | 27     | 26     | 25     | 24     | 23     | 22     | 21     | 20     | 19     | 18     | 17     | 16     |

| Bit     | Bit Name        | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                     |
|---------|-----------------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BA0_31 to BA0_0 | All 0         | R/W | <p>Break Address 0</p> <p>Store an address on the CPU address bus (FAB or MAB) or IAB specifying break conditions of channel 0.</p> <p>When the C bus and instruction fetch cycle are selected by BBR_0, specify an FAB address in bits BA0_31 to BA0_0.</p> <p>When the C bus and data access cycle are selected by BBR_0, specify an MAB address in bits BA0_31 to BA0_0.</p> |

**Note:** When setting the instruction fetch cycle as a break condition, clear the LSB in BAR\_0 to 0.

### 7.3.2 Break Address Mask Register\_0 (BAMR\_0)

BAMR\_0 is a 32-bit readable/writable register. BAMR\_0 specifies bits masked in the break address bits specified by BAR\_0. BAMR\_0 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

|                |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |         |
|----------------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|---------|
| Bit:           | 31      | 30      | 29      | 28      | 27      | 26      | 25      | 24      | 23      | 22      | 21      | 20      | 19      | 18      | 17      | 16      |
|                | BAM0_31 | BAM0_30 | BAM0_29 | BAM0_28 | BAM0_27 | BAM0_26 | BAM0_25 | BAM0_24 | BAM0_23 | BAM0_22 | BAM0_21 | BAM0_20 | BAM0_19 | BAM0_18 | BAM0_17 | BAM0_16 |
| Initial value: | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       | 0       |
| R/W:           | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     | R/W     |

|                |         |         |         |         |         |         |        |        |        |        |        |        |        |        |        |        |

|---------|-------------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31 to 0 | BAM0_31 to BAM0_0 | All 0         | R/W | Break Address Mask 0<br>Specify bits masked in the channel-0 break address bits specified by BAR_0 (BA0_31 to BA0_0).<br>0: Break address bit BA0_n is included in the break condition<br>1: Break address bit BA0_n is masked and not included in the break condition |

Note: n = 31 to 0

### 7.3.3 Break Bus Cycle Register\_0 (BBR\_0)

BBR\_0 is a 16-bit readable/writable register, which specifies (1) disabling or enabling of user break interrupts, (2) including or excluding of the data bus value, (3) bus master of the I bus, (4) C bus cycle or I bus cycle, (5) instruction fetch or data access, (6) read or write, and (7) operand size as the break conditions of channel 0. BBR\_0 is initialized to H'0000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

|                |    |    |       |    |    |          |     |     |          |     |          |     |          |     |          |     |

x: Don't care

### 7.3.4 Break Address Register\_1 (BAR\_1)

BAR\_1 is a 32-bit readable/writable register. BAR\_1 specifies the address used as a break condition in channel 1. The control bits CD1\_1 and CD1\_0 in the break bus cycle register\_1 (BBR\_1) select one of the three address buses for a break condition of channel 1. BAR\_1 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

**Note:** When setting the instruction fetch cycle as a break condition, clear the LSB in BAR\_1 to 0.

### 7.3.5 Break Address Mask Register\_1 (BAMR\_1)

BAMR\_1 is a 32-bit readable/writable register. BAMR\_1 specifies bits masked in the break address bits specified by BAR\_1. BAMR\_1 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

### 7.3.6 Break Bus Cycle Register\_1 (BBR\_1)

BBR\_1 is a 16-bit readable/writable register, which specifies (1) disabling or enabling of user break interrupts, (2) including or excluding of the data bus value, (3) bus master of the I bus, (4) C bus cycle or I bus cycle, (5) instruction fetch or data access, (6) read or write, and (7) operand size as the break conditions of channel 1. BBR\_1 is initialized to H'0000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

x: Don't care

### 7.3.7 Break Address Register\_2 (BAR\_2)

BAR\_2 is a 32-bit readable/writable register. BAR\_2 specifies the address used as a break condition in channel 2. The control bits CD2\_1 and CD2\_0 in the break bus cycle register\_2 (BBR\_2) select one of the three address buses for a break condition of channel 2. BAR\_2 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

**Note:** When setting the instruction fetch cycle as a break condition, clear the LSB in BAR\_2 to 0.

### 7.3.8 Break Address Mask Register\_2 (BAMR\_2)

BAMR\_2 is a 32-bit readable/writable register. BAMR\_2 specifies bits masked in the break address bits specified by BAR\_2. BAMR\_2 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

### 7.3.9 Break Bus Cycle Register\_2 (BBR\_2)

BBR\_2 is a 16-bit readable/writable register, which specifies (1) disabling or enabling of user break interrupts, (2) including or excluding of the data bus value, (3) bus master of the I bus, (4) C bus cycle or I bus cycle, (5) instruction fetch or data access, (6) read or write, and (7) operand size as the break conditions of channel 2. BBR\_2 is initialized to H'0000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

### 7.3.10 Break Address Register\_3 (BAR\_3)

BAR\_3 is a 32-bit readable/writable register. BAR\_3 specifies the address used as a break condition in channel 3. The control bits CD3\_1 and CD3\_0 in the break bus cycle register\_3 (BBR\_3) select one of the three address buses for a break condition of channel 3. BAR\_3 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

**Note:** When setting the instruction fetch cycle as a break condition, clear the LSB in BAR\_3 to 0.

### 7.3.11 Break Address Mask Register\_3 (BAMR\_3)

BAMR\_3 is a 32-bit readable/writable register. BAMR\_3 specifies bits masked in the break address bits specified by BAR\_3. BAMR\_3 is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

### 7.3.12 Break Bus Cycle Register\_3 (BBR\_3)

BBR\_3 is a 16-bit readable/writable register, which specifies (1) disabling or enabling of user break interrupts, (2) including or excluding of the data bus value, (3) bus master of the I bus, (4) C bus cycle or I bus cycle, (5) instruction fetch or data access, (6) read or write, and (7) operand size as the break conditions of channel 3. BBR\_3 is initialized to H'0000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

## [Legend]

x: Don't care

### 7.3.13 Break Control Register (BRCR)

BRCR sets the following conditions:

1. Specifies whether user breaks are set before or after instruction execution.
2. Specifies the pulse width of the  $\overline{\text{UBCTRG}}$  output when a break condition is satisfied.

BRCR is a 32-bit readable/writable register that has break condition match flags and bits for setting other break conditions. For the condition match flags of bits 15 to 12, writing 1 is invalid (previous values are retained) and writing 0 is only possible. To clear the flag, write 0 to the flag bit to be cleared and 1 to all other flag bits. BRCR is initialized to H'00000000 by a power-on reset, but retains its previous value by a manual reset or in software standby mode or sleep mode.

## 7.4 Operation

### 7.4.1 Flow of the User Break Operation

The flow from setting of break conditions to user break interrupt exception handling is described below:

1. The break address is set in a break address register (BAR). The masked address bits are set in a break address mask register (BAMR). The bus break conditions are set in the break bus cycle register (BBR). Three control bit groups of BBR (C bus cycle/I bus cycle select, instruction fetch/data access select, and read/write select) are each set. No user break will be generated if even one of these groups is set to 00. The relevant break control conditions are set in the bits of the break control register (BRCR). Make sure to set all registers related to breaks before setting BBR, and branch after reading from the last written register. The newly written register values become valid from the instruction at the branch destination.
2. In the case where the break conditions are satisfied, the UBC sends a user break interrupt request to the CPU, sets the C bus condition match flag (SCMFC) or I bus condition match flag (SCMFD) for the appropriate channel, and outputs a pulse to the  $\overline{\text{UBCTRG}}$  pin with the width set by the CKS1 and CKS0 bits. Setting the UBID bit in BBR to 1 enables external monitoring of the trigger output without requesting user break interrupts.
3. On receiving a user break interrupt request signal, the INTC determines its priority. Since the user break interrupt has a priority level of 15, it is accepted when the priority level set in the interrupt mask level bits (I3 to I0) of the status register (SR) is 14 or lower. If the I3 to I0 bits are set to a priority level of 15, the user break interrupt is not accepted, but the conditions are checked, and condition match flags are set if the conditions match. For details on ascertaining the priority, see section 6, Interrupt Controller (INTC).
4. Condition match flags (SCMFC and SCMFD) can be used to check which condition has been satisfied. They are set when the conditions match, but are not reset. To use these flags again, write 0 to the corresponding bit of the flags.
5. It is possible that the breaks set in channels 0 to 3 occur around the same time. In this case, there will be only one user break request to the CPU, but these four break channel match flags may be set at the same time.

6. When selecting the I bus as the break condition, note as follows:
  - Several bus masters, including the CPU and DMAC, are connected to the I bus. The UBC monitors bus cycles generated by the bus master specified by BBR, and determines the condition match.
  - I bus cycles (including read fill cycles) resulting from instruction fetches on the C bus by the CPU are defined as instruction fetch cycles on the I bus, while other bus cycles are defined as data access cycles.
  - The DTC and DMAC only issue data access cycles for I bus cycles.
  - If a break condition is specified for the I bus, even when the condition matches in an I bus cycle resulting from an instruction executed by the CPU, at which instruction the user break is to be accepted cannot be clearly defined.

#### 7.4.2 Break on Instruction Fetch Cycle

1. When C bus/instruction fetch/read/word or longword is set in the break bus cycle register (BBR), the break condition is the FAB bus instruction fetch cycle. Whether PC breaks are set before or after the execution of the instruction can then be selected with the PCB0 or PCB1 bit of the break control register (BRCR) for the appropriate channel. If an instruction fetch cycle is set as a break condition, clear LSB in the break address register (BAR) to 0. A break cannot be generated as long as this bit is set to 1.
2. A break for instruction fetch which is set as a break before instruction execution occurs when it is confirmed that the instruction has been fetched and will be executed. This means a break does not occur for instructions fetched by overrun (instructions fetched at a branch or during an interrupt transition, but not to be executed). When this kind of break is set for the delay slot of a delayed branch instruction, the break is not generated until the execution of the first instruction at the branch destination.

Note: If a branch does not occur at a delayed branch instruction, the subsequent instruction is not recognized as a delay slot.

3. When setting a break condition for break after instruction execution, the instruction set with the break condition is executed and then the break is generated prior to execution of the next instruction. As with pre-execution breaks, a break does not occur with overrun fetch instructions. When this kind of break is set for a delayed branch instruction and its delay slot, the break is not generated until the first instruction at the branch destination.
4. When an instruction fetch cycle is set, the break data register (BDR) is ignored. Therefore, break data cannot be set for the break of the instruction fetch cycle.
5. If the I bus is set for a break of an instruction fetch cycle, the setting is invalidated.

### 7.4.3 Break on Data Access Cycle

1. If the C bus is specified as a break condition for data access break, condition comparison is performed for the virtual address accessed by the executed instructions, and a break occurs if the condition is satisfied. If the I bus is specified as a break condition, condition comparison is performed for the physical address of the data access cycles that are issued by the bus master specified by the bits to select the bus master of the I bus, and a break occurs if the condition is satisfied. For details on the CPU bus cycles issued on the I bus, see 6 in section 7.4.1, Flow of the User Break Operation.
2. The relationship between the data access cycle address and the comparison condition for each operand size is listed in table 7.3.

**Table 7.3 Data Access Cycle Addresses and Operand Size Comparison Conditions**

| Access Size | Address Compared                                                         |
|-------------|--------------------------------------------------------------------------|
| Longword    | Compares break address register bits 31 to 2 to address bus bits 31 to 2 |
| Word        | Compares break address register bits 31 to 1 to address bus bits 31 to 1 |
| Byte        | Compares break address register bits 31 to 0 to address bus bits 31 to 0 |

This means that when address H'00001003 is set in the break address register (BAR), for example, the bus cycle in which the break condition is satisfied is as follows (where other conditions are met).

Longword access at H'00001000

Word access at H'00001002

Byte access at H'00001003

3. If the data access cycle is selected, the instruction at which the break will occur cannot be determined.

#### 7.4.4 Value of Saved Program Counter

When a break occurs, the address of the instruction from where execution is to be resumed is saved to the stack, and the exception handling state is entered. If the C bus (FAB)/instruction fetch cycle is specified as a break condition, the instruction at which the break should occur can be uniquely determined. If the C bus/data access cycle or I bus/data access cycle is specified as a break condition, the instruction at which the break should occur cannot be uniquely determined.

1. When C bus (FAB)/instruction fetch (before instruction execution) is specified as a break condition:

The address of the instruction that matched the break condition is saved to the stack. The instruction that matched the condition is not executed, and the break occurs before it. However when a delay slot instruction matches the condition, the instruction is executed, and the branch destination address is saved to the stack.

2. When C bus (FAB)/instruction fetch (after instruction execution) is specified as a break condition:

The address of the instruction following the instruction that matched the break condition is saved to the stack. The instruction that matches the condition is executed, and the break occurs before the next instruction is executed. However when a delayed branch instruction or delay slot matches the condition, the instruction is executed, and the branch destination address is saved to the stack.

3. When C bus/data access cycle or I bus/data access cycle is specified as a break condition:

The address after executing several instructions of the instruction that matched the break condition is saved to the stack.

## 7.4.5 Usage Examples

### (1) Break Condition Specified for C Bus Instruction Fetch Cycle

(Example 1-1)

- Register specifications

BAR\_0 = H'00000404, BAMR\_0 = H'00000000, BBR\_0 = H'0054, BAR\_1 = H'00008010,  
BAMR\_1 = H'00000006, BBR\_1 = H'0054, BRCR = H'00000020

<Channel 0>

Address: H'00000404, Address mask: H'00000000

Bus cycle: C bus/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

<Channel 1>

Address: H'00008010, Address mask: H'00000006

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

A user break occurs after an instruction of address H'00000404 is executed or before instructions of addresses H'00008010 to H'00008016 are executed.

(Example 1-2)

- Register specifications

BAR\_0 = H'00027128, BAMR\_0 = H'00000000, BBR\_0 = H'005A, BAR\_1 = H'00031415,  
BAMR\_1 = H'00000000, BBR\_1 = H'0054, BRCR = H'00000000

<Channel 0>

Address: H'00027128, Address mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/write/word

<Channel 1>

Address: H'00031415, Address mask: H'00000000

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

On channel 0, a user break does not occur since instruction fetch is not a write cycle. On channel 1, a user break does not occur since instruction fetch is performed for an even address.

## (Example 1-3)

- Register specifications

BBR\_0 = H'0054, BAR\_0 = H'00008404, BAMR\_0 = H'00000FFF, BBR\_1 = H'0054,  
BAR\_1 = H'00008010, BAMR\_1 = H'00000006, BRCR = H'00000020

<Channel 0>

Address: H'00008404, Address mask: H'00000FFF

Bus cycle: C bus/instruction fetch (after instruction execution)/read (operand size is not included in the condition)

<Channel 1>

Address: H'00008010, Address mask: H'00000006

Bus cycle: C bus/instruction fetch (before instruction execution)/read (operand size is not included in the condition)

A user break occurs after an instruction with addresses H'00008000 to H'00008FFE is executed or before an instruction with addresses H'00008010 to H'00008016 are executed.

**(2) Break Condition Specified for C Bus Data Access Cycle**

## (Example 2-1)

- Register specifications

BBR\_0 = H'0064, BAR\_0 = H'00123456, BAMR\_0 = H'00000000,  
BBR\_1 = H'006A, BAR\_1 = H'000ABCDE, BAMR\_1 = H'000000FF, BRCR = H'00000000

<Channel 0>

Address: H'00123456, Address mask: H'00000000

Bus cycle: C bus/data access/read (operand size is not included in the condition)

<Channel 1>

Address: H'000ABCDE, Address mask: H'000000FF

Bus cycle: C bus/data access/write/word

On channel 0, a user break occurs with longword read from address H'00123456, word read from address H'00123456, or byte read from address H'00123456. On channel 1, a user break occurs when word is written in addresses H'000ABC00 to H'000ABCFE.

### (3) Break Condition Specified for I Bus Data Access Cycle

(Example 3-1)

- Register specifications

BBR\_0 = H'0094, BAR\_0 = H'00314156, BAMR\_0 = H'00000000,

BBR\_1 = H'12A9, BAR\_1 = H'00055555, BAMR\_1 = H'00000000, BRCR = H'00000000

<Channel 0>

Address: H'00314156, Address mask: H'00000000

Bus cycle: I bus/instruction fetch/read (operand size is not included in the condition)

<Channel 1>

Address: H'00055555, Address mask: H'00000000

Bus cycle: I bus/data access/write/byte

On channel 0, the setting of I bus/instruction fetch is ignored.

On channel 1, a user break occurs when the DMAC writes byte data in address H'00055555 on the I bus (write by the CPU does not generate a user break).

## 7.5 Interrupt Source

The UBC has the user break source as an interrupt source.

Table 7.4 gives details on this interrupt source.

A user break interrupt is generated when one of the compare match flags (SCMFD3 to SCMFD0 and SCMFC3 to SCMFC0) in the break control register (BRCR) is set to 1. Clearing the interrupt flag bit to 0 cancels the interrupt request.

**Table 7.4 Interrupt Source**

| Abbreviation | Interrupt Source     | Interrupt Enable Bit | Interrupt Flag                                                          | Interrupt Level |
|--------------|----------------------|----------------------|-------------------------------------------------------------------------|-----------------|
| User break   | User break interrupt | —                    | SCMFD3, SCMFD2,<br>SCMFD1, SCMFD0,<br>SCMFC3, SCMFC2,<br>SCMFC1, SCMFC0 | Fixed to 15     |

## 7.6 Usage Notes

1. The CPU can read from or write to the UBC registers via the I bus. Accordingly, during the period from executing an instruction to rewrite the UBC register till the new value is actually rewritten, the desired break may not occur. In order to know the timing when the UBC register is changed, read from the last written register. Instructions after then are valid for the newly written register value.
2. The UBC cannot monitor access to the C bus and I bus cycles in the same channel.
3. When a user break and another exception occur at the same instruction, which has higher priority is determined according to the priority levels defined in table 5.1 in section 5, Exception Handling. If an exception with a higher priority occurs, the user break does not occur.
4. Note the following when a break occurs in a delay slot.  
If a pre-execution break is set at a delay slot instruction, the break is not generated until immediately before execution of the branch destination.
5. User breaks are disabled during UBC module standby mode. Do not read from or write to the UBC registers during UBC module standby mode; the values are not guaranteed.
6. Do not set an address within an interrupt exception handling routine whose interrupt priority level is at least 15 (including user break interrupts) as a break address.
7. Do not set break after instruction execution for the SLEEP instruction or for the delayed branch instruction where the SLEEP instruction is placed at its delay slot.
8. When setting a break for a 32-bit instruction, set the address where the upper 16 bits are placed. If the address of the lower 16 bits is set and a break before instruction execution is set as a break condition, the break is handled as a break after instruction execution.
9. Do not set a pre-execution break for an instruction that immediately follows a DIVU or DIVS instruction. If such a break is set and an interrupt or other exception occurs during execution of the DIVU or DIVS instruction, the pre-execution break will still occur even though execution of the DIVU or DIVS instruction is suspended.
10. Do not set a pre- and post-execution break for the same address at the same time. For example, if a pre-execution break for channel 0 and a post-execution break for channel 1 are set for the same address at the same time, the condition match flags on channel 1 after instruction execution will be set even though a pre-execution break has occurred on channel 0.

## Section 8 Data Transfer Controller (DTC)

This LSI includes a data transfer controller (DTC). The DTC can be activated to transfer data by an interrupt request.

### 8.1 Features

- Transfer possible over any number of channels
- Chain transfer  
Multiple rounds of data transfer is executed in response to a single activation source  
Chain transfer is only possible after data transfer has been done for the specified number of times (i.e. when the transfer counter is 0)
- Three transfer modes  
Normal/repeat/block transfer modes selectable  
Transfer source and destination addresses can be selected from increment/decrement/fixed
- The transfer source and destination addresses can be specified by 32 bits to select a 4-Gbyte address space directly
- Size of data for data transfer can be specified as byte, word, or longword
- A CPU interrupt can be requested for the interrupt that activated the DTC  
A CPU interrupt can be requested after one data transfer completion  
A CPU interrupt can be requested after the specified data transfer completion
- Read skip of the transfer information specifiable
- Write-back skip executed for the fixed transfer source and destination addresses
- Module stop mode specifiable
- Short address mode specifiable
- Bus release timing selectable: Three types
- DTC activation priority selectable: Two types

Figure 8.1 shows a block diagram of the DTC. The DTC transfer information can be allocated to the data area\*.

**Note:** When the transfer information is stored in the on-chip RAM, the RAME bits in SYSCR1 and SYSCR2 must be set to 1.

**Figure 8.1 Block Diagram of DTC**

## 8.2 Register Descriptions

DTC has the following registers. For details on the addresses of these registers and the states of these registers in each processing state, see section 32, List of Registers.

These six registers MRA, MRB, SAR, DAR, CRA, and CRB cannot be directly accessed by the CPU. The contents of these registers are stored in the data area as transfer information. When a DTC activation request occurs, the DTC reads a start address of transfer information that is stored in the data area according to the vector address, reads the transfer information, and transfers data. After the data transfer is complete, it writes a set of updated transfer information back to the data area.

On the other hand, DTCERA to DTCERE, DTCCR, and DTCVBR can be directly accessed by the CPU.

**Table 8.1 Register Configuration**

| Register Name                   | Abbrevia-<br>tion | R/W | Initial Value | Address    | Access Size |
|---------------------------------|-------------------|-----|---------------|------------|-------------|
| DTC enable register A           | DTCERA            | R/W | H'0000        | H'FFFE6000 | 8, 16       |
| DTC enable register B           | DTCERB            | R/W | H'0000        | H'FFFE6002 | 8, 16       |
| DTC enable register C           | DTCERC            | R/W | H'0000        | H'FFFE6004 | 8, 16       |
| DTC enable register D           | DTCERD            | R/W | H'0000        | H'FFFE6006 | 8, 16       |
| DTC enable register E           | DTCERE            | R/W | H'0000        | H'FFFE6008 | 8, 16       |
| DTC control register            | DTCCR             | R/W | H'00          | H'FFFE6010 | 8           |
| DTC vector base register        | DTCVBR            | R/W | H'00000000    | H'FFFE6014 | 8, 16, 32   |
| Bus function extending register | BSCEHR            | R/W | H'0000        | H'FFFE3C1A | 16          |

### 8.2.1 DTC Mode Register A (MRA)

MRA selects DTC operating mode. MRA cannot be accessed directly by the CPU.

|                |         |   |         |   |         |   |   |   |
|----------------|---------|---|---------|---|---------|---|---|---|
| Bit:           | 7       | 6 | 5       | 4 | 3       | 2 | 1 | 0 |

### 8.2.3 DTC Source Address Register (SAR)

SAR is a 32-bit register that designates the source address of data to be transferred by the DTC.

SAR cannot be accessed directly from the CPU.

## 8.2.4 DTC Destination Address Register (DAR)

DAR is a 32-bit register that designates the destination address of data to be transferred by the DTC.

DAR cannot be accessed directly from the CPU.

## 8.2.5 DTC Transfer Count Register A (CRA)

CRA is a 16-bit register that designates the number of times data is to be transferred by the DTC.

In normal transfer mode, CRA functions as a 16-bit transfer counter (1 to 65,536). It is decremented by 1 every time data is transferred, and bit DTCEn (n = 15 to 0) corresponding to the activation source is cleared and then an interrupt is requested to the CPU when the count reaches H'0000. The transfer count is 1 when CRA = H'0001, 65,535 when CRA = H'FFFF, and 65,536 when CRA = H'0000.

In repeat transfer mode, CRA is divided into two parts: the upper eight bits (CRAH) and the lower eight bits (CRAL). CRAH holds the number of transfers while CRAL functions as an 8-bit transfer counter (1 to 256). CRAL is decremented by 1 every time data is transferred, and the contents of CRAH are sent to CRAL when the count reaches H'00. The transfer count is 1 when CRAH = CRAL = H'01, 255 when CRAH = CRAL = H'FF, and 256 when CRAH = CRAL = H'00.

In block transfer mode, CRA is divided into two parts: the upper eight bits (CRAH) and the lower eight bits (CRAL). CRAH holds the block size while CRAL functions as an 8-bit block-size counter (1 to 256 for byte, word, or longword). CRAL is decremented by 1 every time a byte (word or longword) data is transferred, and the contents of CRAH are sent to CRAL when the count reaches H'00. The block size is 1 byte (word or longword) when CRAH = CRAL = H'01, 255 bytes (words or longwords) when CRAH = CRAL = H'FF, and 256 bytes (words or longwords) when CRAH = CRAL = H'00.

CRA cannot be accessed directly from the CPU.

\*: Undefined

## 8.2.6 DTC Transfer Count Register B (CRB)

CRB is a 16-bit register that designates the number of times data is to be transferred by the DTC in block transfer mode. It functions as a 16-bit transfer counter (1 to 65,536) that is decremented by 1 every time a block of data is transferred, and bit DTCEn (n = 15 to 0) corresponding to the activation source is cleared and then an interrupt is requested to the CPU when the count reaches H'0000. The transfer count is 1 when CRB = H'0001, 65,535 when CRB = H'FFFF, and 65,536 when CRB = H'0000.

CRB is not available in normal and repeat modes and cannot be accessed directly by the CPU.

| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

## 8.2.7 DTC Enable Registers A to E (DTCERA to DTCERE)

DTCER which is comprised of eight registers, DTCERA to DTCERE, is a register that specifies DTC activation interrupt sources. The correspondence between interrupt sources and DTCE bits is shown in table 8.2.

The DTC halts after a data transfer or a transfer information writing state depending on the NMI input timing.</p> <p>Note that a writing state is not exact, when the DTC halts after a data transfer. When the data is transferred, set a transfer information once again (except that a read skip is performed).</p> <p>0: No interrupt has occurred<br/>1: An interrupt has occurred</p> <p>[Clearing condition]</p> <ul style="list-style-type: none"> <li>When writing 0 after reading 1</li> </ul> |

Note: \* Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

## 8.2.9 DTC Vector Base Register (DTCVBR)

DTCVBR is a 32-bit register that specifies the base address for vector table address calculation.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |

### 8.2.10 Bus Function Extending Register (BSCEHR)

BSCEHR is a 16-bit register that specifies the timing of bus release by the DTC and other functions. This register should be used to give priority to the DTC transfer or reduce the number of cycles in which the DTC is active. For more details, see section 9.4.8, Bus Function Extending Register (BSCEHR).

## 8.3 Activation Sources

The DTC is activated by an interrupt request. The interrupt source is selected by DTCER. A DTC activation source can be selected by setting the corresponding bit in DTCER; the CPU interrupt source can be selected by clearing the corresponding bit in DTCER. At the end of a data transfer (or the last consecutive transfer in the case of chain transfer), the activation source interrupt flag or corresponding DTCER bit is cleared.

## 8.4 Location of Transfer Information and DTC Vector Table

Locate the transfer information in the data area. The start address of transfer information should be located at the address that is a multiple of four (4n). Otherwise, the lower two bits are ignored during access ([1:0] = B'00.) Transfer information located in the data area is shown in figure 8.2.

Short address mode can be selected by setting the DTSA bit in the bus function extending register (BSCEHR) to 1 only when all DTC transfer sources and destinations are located in the on-chip RAM and on-chip peripheral module areas (see section 9.4.8, Bus Function Extending Register (BSCEHR)).

In normal transfer, four longwords should be read as the transfer information; in short address mode, the transfer information is reduced to three longwords and the DTC active period becomes shorter.

The DTC reads the start address of transfer information from the vector table according to the activation source, and then reads the transfer information from the start address. Figure 8.3 shows correspondences between the DTC vector address and transfer information.

**Figure 8.2 Transfer Information on Data Area**

**Figure 8.3 Correspondence between DTC Vector Address and Transfer Information**

Table 8.2 shows correspondence between the DTC activation source and vector address.

**Table 8.2 Interrupt Sources, DTC Vector Addresses, and Corresponding DTCEs**

|                                   | TXI3                 | 255              | H'000007FC        | DTCERE8            | Any location <sup>*2</sup> | SCFTDR_3                   |                                                          |

Notes: 1. The DTCE bits with no corresponding interrupt are reserved, and the write value should always be 0.

2. An external memory, a memory-mapped external device, an on-chip memory, or an on-chip peripheral module (except for DTC, BSC, UBC, AUD, FLASH, and DMAC) can be selected as the source or destination. Note that at least either the source or destination must be an on-chip peripheral module; transfer cannot be done among an external memory, a memory-mapped external device, and an on-chip memory.

3. Read to a message control field in mailbox 0 by using a block transfer mode or etc.

## 8.5 Operation

There are three transfer modes: normal, repeat, and block. Since transfer information is in the data area, it is possible to transfer data over any required number of channels. When activated, the DTC reads the transfer information stored in the data area and transfers data according to the transfer information. After the data transfer is complete, it writes updated transfer information back to the data area.

The DTC specifies the source address and destination address in SAR and DAR, respectively. After a transfer, SAR and DAR are incremented, decremented, or fixed independently.

Table 8.3 shows the DTC transfer modes.

**Table 8.3 DTC Transfer Modes**

| <b>Transfer Mode</b> | <b>Size of Data Transferred at One Transfer Request</b>       | <b>Memory Address Increment or Decrement</b>    | <b>Transfer Count</b>    |
|----------------------|---------------------------------------------------------------|-------------------------------------------------|--------------------------|
| Normal               | 1 byte/word/longword                                          | Incremented/decremented by 1, 2, or 4, or fixed | 1 to 65536               |
| Repeat* <sup>1</sup> | 1 byte/word/longword                                          | Incremented/decremented by 1, 2, or 4, or fixed | 1 to 256* <sup>3</sup>   |
| Block* <sup>2</sup>  | Block size specified by CRAH (1 to 256 bytes/words/longwords) | Incremented/decremented by 1, 2, or 4, or fixed | 1 to 65536* <sup>4</sup> |

Notes: 1. Either source or destination is specified to repeat area.  
 2. Either source or destination is specified to block area.  
 3. After transfer of the specified transfer count, initial state is recovered to continue the operation.  
 4. Number of transfers of the specified block size of data

Setting the CHNE bit in MRB to 1 makes it possible to perform a number of transfers with a single activation (chain transfer). Setting the CHNS bit in MRB to 1 can also be made to have chain transfer performed only when the transfer counter value is 0.

Figure 8.4 shows a flowchart of DTC operation, and table 8.4 summarizes the conditions for DTC transfers including chain transfer (combinations for performing the second and third transfers are omitted).

Figure 8.4 Flowchart of DTC Operation

**Table 8.4 DTC Transfer Conditions (Chain Transfer Conditions Included)**

| Transfer Mode | 1st Transfer |      |       |       |                                | 2nd Transfer |      |       |       |                                | DTC Transfer             |

Notes: 1. CRA in normal mode transfer, CRAL in repeat transfer mode, or CRB in block transfer mode

2. When the contents of the CRAH is written to the CRAL

### 8.5.1 Transfer Information Read Skip Function

By setting the RRS bit of DTCCR, the vector address read and transfer information read can be skipped. The current DTC vector number is always compared with the vector number of previous activation. If the vector numbers match when RRS = 1, a DTC data transfer is performed without reading the vector address and transfer information. If the previous activation is a chain transfer, the vector address read and transfer information read are always performed. Figure 8.5 shows the transfer information read skip timing.

To modify the vector table and transfer information, temporarily clear the RRS bit to 0, modify the vector table and transfer information, and then set the RRS bit to 1 again. When the RRS bit is cleared to 0, the stored vector number is deleted, and the updated vector table and transfer information are read at the next activation.

**Figure 8.5 Transfer Information Read Skip Timing**  
 (Activated by On-Chip Peripheral Module; Iφ : Bφ : Pφ = 1 : 1/2 : 1/2;  
 Data Transferred from On-Chip Peripheral Module to On-Chip RAM;  
 Transfer Information is Written in 3 Cycles)

## 8.5.2 Transfer Information Write-Back Skip Function

By specifying bit SM1 in MRA and bit DM1 in MRB to the fixed address mode, a part of transfer information will not be written back. Table 8.5 shows the transfer information write-back skip condition and write-back skipped registers. Note that the CRA and CRB are always written back. The write-back of the MRA and MRB are always skipped.

**Table 8.5 Transfer Information Write-Back Skip Condition and Write-Back Skipped Registers**

| SM1 | DM1 | SAR          | DAR          |
|-----|-----|--------------|--------------|
| 0   | 0   | Skipped      | Skipped      |
| 0   | 1   | Skipped      | Written back |
| 1   | 0   | Written back | Skipped      |
| 1   | 1   | Written back | Written back |

## 8.5.3 Normal Transfer Mode

In normal transfer mode, data are transferred in one byte, one word, or one longword units in response to a single activation request. From 1 to 65,536 transfers can be specified. The transfer source and destination addresses can be specified as incremented, decremented, or fixed. When the specified number of transfers ends, an interrupt can be requested to the CPU.

Table 8.6 lists the register function in normal transfer mode. Figure 8.6 shows the memory map in normal transfer mode.

**Table 8.6 Register Function in Normal Transfer Mode**

| Register | Function            | Written Back Value             |
|----------|---------------------|--------------------------------|
| SAR      | Source address      | Incremented/decremented/fixed* |
| DAR      | Destination address | Incremented/decremented/fixed* |
| CRA      | Transfer count A    | CRA – 1                        |
| CRB      | Transfer count B    | Not updated                    |

Note: \* Transfer information write-back is skipped.

**Figure 8.6 Memory Map in Normal Transfer Mode**

### 8.5.4 Repeat Transfer Mode

In repeat transfer mode, data are transferred in one byte, one word, or one longword units in response to a single activation request. By the DTS bit in MRB, either the source or destination can be specified as a repeat area. From 1 to 256 transfers can be specified. When the specified number of transfers ends, the transfer counter and address register specified as the repeat area is restored to the initial state, and transfer is repeated. The other address register is then incremented, decremented, or left fixed. In repeat transfer mode, the transfer counter (CRAL) is updated to the value specified in CRAH when CRAL becomes H'00. Thus the transfer counter value does not reach H'00, and therefore a CPU interrupt cannot be requested when DISEL = 0.

Table 8.7 lists the register function in repeat transfer mode. Figure 8.7 shows the memory map in repeat transfer mode.

**Table 8.7 Register Function in Repeat Transfer Mode**

| Register | Function               | Written Back Value             |                                                                       |
|----------|------------------------|--------------------------------|-----------------------------------------------------------------------|
|          |                        | CRAL is not 1                  | CRAL is 1                                                             |
| SAR      | Source address         | Incremented/decremented/fixed* | DTS = 0: Incremented/decremented/fixed*<br>DTS = 1: SAR initial value |
| DAR      | Destination address    | Incremented/decremented/fixed* | DTS = 0: DAR initial value<br>DTS = 1: Incremented/decremented/fixed* |
| CRAH     | Transfer count storage | CRAH                           | CRAH                                                                  |
| CRAL     | Transfer count A       | CRAL – 1                       | CRAH                                                                  |
| CRB      | Transfer count B       | Not updated                    | Not updated                                                           |

Note: \* Transfer information write-back is skipped.

**Figure 8.7 Memory Map in Repeat Transfer Mode  
(When Transfer Source is Specified as Repeat Area)**

### 8.5.5 Block Transfer Mode

In block transfer mode, data are transferred in block units in response to a single activation request. Either the transfer source or the transfer destination is designated as a block area by the DTS bit in MRB.

The block size is 1 to 256 bytes (1 to 256 words, or 1 to 256 longwords). When transfer of one block of data ends, the block size counter (CRAL) and address register (SAR when DTS = 1 or DAR when DTS = 0) for the area specified as the block area are initialized. The other address register is then incremented, decremented, or left fixed. From 1 to 65,536 transfers can be specified. When the specified number of transfers ends, an interrupt is requested to the CPU.

Table 8.8 lists the register function in block transfer mode. Figure 8.8 shows the memory map in block transfer mode.

**Table 8.8 Register Function in Block Transfer Mode**

| Register | Function               | Written Back Value                                                    |
|----------|------------------------|-----------------------------------------------------------------------|
| SAR      | Source address         | DTS = 0: Incremented/decremented/fixed*<br>DTS = 1: SAR initial value |
| DAR      | Destination address    | DTS = 0: DAR initial value<br>DTS = 1: Incremented/decremented/fixed* |
| CRAH     | Block size storage     | CRAH                                                                  |
| CRAL     | Block size counter     | CRAH                                                                  |
| CRB      | Block transfer counter | CRB – 1                                                               |

Note: \* Transfer information write-back is skipped.

**Figure 8.8 Memory Map in Block Transfer Mode  
(When Transfer Destination is Specified as Block Area)**

### 8.5.6 Chain Transfer

Setting the CHNE bit in MRB to 1 enables a number of data transfers to be performed consecutively in response to a single transfer request. Setting the CHNE and CHNS bits in MRB set to 1 enables a chain transfer only when the transfer counter reaches 0. SAR, DAR, CRA, CRB, MRA, and MRB, which define data transfers, can be set independently. Figure 8.9 shows the chain transfer operation.

In the case of transfer with CHNE set to 1, an interrupt request to the CPU is not generated at the end of the specified number of transfers or by setting the DISEL bit to 1, and the interrupt source flag for the activation source and DTCER are not affected.

In repeat transfer mode, setting the RCHNE bit in DTCCR and the CHNE and CHNS bits in MRB to 1 enables a chain transfer after transfer with transfer counter = 1 has been completed.

**Figure 8.9 Operation of Chain Transfer**

## 8.5.7 Operation Timing

Figures 8.10 to 8.15 show the DTC operation timings.

**Figure 8.10 Example of DTC Operation Timing:

|                                   | Word data write S <sub>M</sub>            | 1B $\phi$ to 3B $\phi$ <sup>*1</sup>    | —                                                | 1B $\phi$ + 2P $\phi$ <sup>*3</sup> | 1B $\phi$ + 2P $\phi$ <sup>*3</sup> | —                                   | 2B $\phi$ <sup>*6</sup>       | 2B $\phi$ <sup>*6</sup> | 2B $\phi$ <sup>*6</sup> |
|                                   | Longword data write S <sub>M</sub>        | 1B $\phi$ to 3B $\phi$ <sup>*1</sup>    | —                                                | 1B $\phi$ + 4P $\phi$ <sup>*3</sup> | 1B $\phi$ + 2P $\phi$ <sup>*3</sup> | 1B $\phi$ + 4P $\phi$ <sup>*3</sup> | 2B $\phi$ <sup>*6</sup>       | 2B $\phi$ <sup>*6</sup> | 2B $\phi$ <sup>*6</sup> |
| Internal operation S <sub>N</sub> |                                           |                                         |                                                  |                                     | 1                                   |                                     |                               |                         |                         |

Notes: 1. Values for on-chip RAM. Number of cycles varies depending on the ratio of I $\phi$ :B $\phi$ .

|                            | Read                  | Write                 |
|----------------------------|-----------------------|-----------------------|
| I $\phi$ :B $\phi$ = 1:1   | 3B $\phi$ , 4B $\phi$ | 2B $\phi$ , 3B $\phi$ |
| I $\phi$ :B $\phi$ = 1:1/2 | 2B $\phi$ , 3B $\phi$ | 2B $\phi$             |
| I $\phi$ :B $\phi$ = 1:1/4 | 2B $\phi$             | 1B $\phi$ , 2B $\phi$ |
| I $\phi$ :B $\phi$ = 1:1/8 | 1B $\phi$             | 1B $\phi$             |

2. Values for the flash memory (ROM). Number of cycles varies depending on the ratio of  $I\phi:B\phi$ .

| Read                  |                   |
|-----------------------|-------------------|
| $I\phi:B\phi = 1:1$   | $4I\phi + 3B\phi$ |
| $I\phi:B\phi = 1:1/2$ | $4I\phi + 3B\phi$ |
| $I\phi:B\phi = 1:1/4$ | $4I\phi + 3B\phi$ |
| $I\phi:B\phi = 1:1/8$ | $3B\phi$          |

3. The values in the table are those for the fastest case. Depending on the state of the internal bus, replace  $1B\phi$  by  $1P\phi$  in a slow case.
4. The EtherC and E-DMAC are not included.
5. Values are different depending on the BSC register setting. The values in the table are the sample for the case with no wait cycles and the WM bit in CSnWCR = 1.
6. Values are different depending on the bus state.  
The number of cycles increases when many external wait cycles are inserted in the case where writing is frequently executed, such as block transfer, and when the external bus is in use because the write buffer cannot be used efficiently in such cases. For details on the write buffer, see section 9.5.12 (2), Access from the Side of the LSI Internal Bus Master.

The number of execution cycles is calculated from the formula below. Note that  $\Sigma$  means the sum of cycles for all transfers initiated by one activation event (the number of 1-valued CHNE bits in transfer information plus 1).

$$\text{Number of execution cycles} = I \cdot S_I + \Sigma (J \cdot S_J + K \cdot S_K + L \cdot S_L + M \cdot S_M) + N \cdot S_N$$

### 8.5.9 DTC Bus Release Timing

The DTC requests the bus mastership of the internal bus (I bus) to the bus arbiter when an activation request occurs. The DTC releases the bus after a vector read, transfer information read, a single data transfer, or transfer information write-back. The DTC does not release the bus mastership during transfer information read, a single data transfer, or write-back of transfer information.

The bus release timing can be specified through the bus function extending register (BSCEHR). For details see section 9.4.8, Bus Function Extending Register (BSCEHR). The difference in bus release timing according to the register setting is summarized in table 8.11. Settings other than shown in the table are prohibited. The value of BSCEHR must not be modified while the DTC is active.

Figure 8.16 is a timing chart showing an example of bus release timing.

**Table 8.11 DTC Bus Release Timing**

|                         | Bus Function Extending<br>Register (BSCEHR)<br>Setting |       | Bus Release Timing<br>(O: Bus must be released;<br>x: Bus is not released) |                                          |                                    |                                             |                        |
|-------------------------|--------------------------------------------------------|-------|----------------------------------------------------------------------------|------------------------------------------|------------------------------------|---------------------------------------------|------------------------|
|                         | DTLOCK                                                 | DTBST | After Vector<br>Read                                                       | After<br>Transfer<br>Information<br>Read | After a<br>Single data<br>Transfer | After Write-Back of<br>Transfer Information |                        |
|                         |                                                        |       |                                                                            |                                          |                                    | Normal<br>Transfer                          | Continuous<br>Transfer |
| Setting 1               | 0                                                      | 0     | x                                                                          | x                                        | x                                  | O                                           | O                      |
| Setting 2* <sup>1</sup> | 0                                                      | 1     | x                                                                          | x                                        | x                                  | O                                           | x                      |
| Setting 3* <sup>2</sup> | 1                                                      | 0     | O                                                                          | O                                        | O                                  | O                                           | O                      |

Notes: 1. The following restrictions apply to setting 2.

- The clock setting through the frequency control register (FRQCR) must be  $I\phi : B\phi : P\phi : M\phi : A\phi = 16 : 4 : 4 : 4 : 4$ ,  $16 : 4 : 4 : 8 : 4$ ,  $8 : 4 : 4 : 8 : 4$ , or  $8 : 4 : 4 : 4 : 4$ .
- The vector information must be stored in the flash memory (ROM) or on-chip RAM.
- The transfer information must be stored in the on-chip RAM.
- Transfer must be between the on-chip RAM and an on-chip peripheral module or between the external memory and an on-chip peripheral module.

2. The following restriction applies to setting 3.

- Use the DTPR bit in BSCEHR with this bit set to 0. Setting this bit to 1 is prohibited.

**Figure 8.16 Example of DTC Operation Timing:  
 Conflict of Two Activation Requests in Normal Transfer Mode  
 (Activated by On-Chip Peripheral Module; I<sub>φ</sub> : B<sub>φ</sub> : P<sub>φ</sub> = 1 : 1/2 : 1/2;  
 Data Transferred from On-Chip Peripheral Module to On-Chip RAM;  
 Transfer Information is Written in 3 Cycles)**

### 8.5.10 DTC Activation Priority Order

If multiple DTC activation requests are generated while the DTC is inactive, whether to start the DTC transfer from the first activation request\* or according to the DTC activation priority can be selected through the DTPR bit setting in the bus function extending register (BSCEHR). If multiple activation requests are generated while the DTC is active, transfer is performed according to the DTC activation priority. Figure 8.17 shows an example of DTC activation according to the priority.

Note: \* When one DTC-activation request is generated before another, transfer starts with the first request. When an activation request with a higher priority is generated before a pending DTC request is accepted, transfer starts for the request with higher priority. Timing of DTC request generation varies according to the operating state of internal buses.

**Figure 8.17 Example of DTC Activation According to Priority**

## 8.6 DTC Activation by Interrupt

The procedure for using the DTC with interrupt activation is shown in figure 8.18.

**Figure 8.18 DTC Activation by Interrupt**

## 8.7 Examples of Use of the DTC

### 8.7.1 Normal Transfer Mode

An example is shown in which the DTC is used to receive 128 bytes of data via the SCI.

1. Set MRA to fixed source address (SM1 = SM0 = 0), incrementing destination address (DM1 = 1, DM0 = 0), normal transfer mode (MD1 = MD0 = 0), and byte size (Sz1 = Sz0 = 0). The DTS bit can have any value. Set MRB for one data transfer by one interrupt (CHNE = 0, DISEL = 0). Set the RDR address of the SCI in SAR, the start address of the RAM area where the data will be received in DAR, and 128 (H'0080) in CRA. CRB can be set to any value.
2. Set the start address of the transfer information for an RXI interrupt at the DTC vector address.
3. Set the corresponding bit in DTCER to 1.
4. Set the SCI to the appropriate receive mode. Set the RIE bit in SCR to 1 to enable the receive end (RXI) interrupt. Since the generation of a receive error during the SCI reception operation will disable subsequent reception, the CPU should be enabled to accept receive error interrupts.
5. Each time reception of one byte of data ends on the SCI, the RDRF flag in SSR is set to 1, an RXI interrupt is generated, and the DTC is activated. The receive data is transferred from RDR to RAM by the DTC. DAR is incremented and CRA is decremented. The RDRF flag is automatically cleared to 0.
6. When CRA becomes 0 after the 128 data transfers have ended, the RDRF flag is held at 1, the DTCE bit is cleared to 0, and an RXI interrupt request is sent to the CPU. Termination processing should be performed in the interrupt handling routine.

## 8.7.2 Chain Transfer when Transfer Counter = 0

By executing a second data transfer and performing re-setting of the first data transfer only when the counter value is 0, it is possible to perform 256 or more repeat transfers.

An example is shown in which a 128-Kbyte input buffer is configured. The input buffer is assumed to have been set to start at lower address H'0000. Figure 8.19 shows the chain transfer when the counter value is 0.

1. For the first transfer, set the normal transfer mode for input data. Set the fixed transfer source address, CRA = H'0000 (65,536 times), CHNE = 1, CHNS = 1, and DISEL = 0.
2. Prepare the upper 8-bit addresses of the start addresses for 65,536-transfer units for the first data transfer in a separate area (in the flash memory (ROM), etc.). For example, if the input buffer is configured at addresses H'200000 to H'21FFFF, prepare H'21 and H'20.
3. For the second transfer, set repeat transfer mode (with the source side as the repeat area) for re-setting the transfer destination address for the first data transfer. Use the upper eight bits of DAR in the first transfer information area as the transfer destination. Set CHNE = DISEL = 0. If the above input buffer is specified as H'200000 to H'21FFFF, set the transfer counter to 2.
4. Execute the first data transfer 65536 times by means of interrupts. When the transfer counter for the first data transfer reaches 0, the second data transfer is started. Set the upper eight bits of the transfer source address for the first data transfer to H'21. The lower 16 bits of the transfer destination address of the first data transfer and the transfer counter are H'0000.
5. Next, execute the first data transfer the 65536 times specified for the first data transfer by means of interrupts. When the transfer counter for the first data transfer reaches 0, the second data transfer is started. Set the upper eight bits of the transfer source address for the first data transfer to H'20. The lower 16 bits of the transfer destination address of the first data transfer and the transfer counter are H'0000.
6. Steps 4 and 5 are repeated endlessly. As repeat mode is specified for the second data transfer, no interrupt request is sent to the CPU.

**Figure 8.19 Chain Transfer when Transfer Counter = 0**

## 8.8 Interrupt Sources

An interrupt request is issued to the CPU when the DTC finishes the specified number of data transfers, or on completion of a single data transfer or a single block data transfer with the DISEL bit set to 1. In the case of interrupt activation, the interrupt set as the activation source is generated. These interrupts to the CPU are subject to CPU mask level and priority level control in the interrupt controller. For details, refer to section 6.9, Data Transfer with Interrupt Request Signals.

## 8.9 Usage Notes

### 8.9.1 Module Standby Mode Setting

Operation of the DTC can be disabled or enabled using the standby control register. The initial setting is for operation of the DTC to be enabled. DTC operation and access are disabled in module standby mode. Do not place the DTC in module standby mode while it is active. Before entering software standby mode or module standby mode, all DTCER registers must be cleared. For details, refer to section 30, Power-Down Modes.

### 8.9.2 On-Chip RAM

Transfer information can be located in on-chip RAM. In this case, the corresponding RAME bits in SYSCR1 and SYSCR2 must not be cleared to 0.

### 8.9.3 DTCE Bit Setting

To set a DTCE bit, disable the corresponding interrupt, read 0 from the bit, and then write 1 to it. While DTC transfer is in progress, do not modify the DTCE bits.

### 8.9.4 Chain Transfer

When chain transfer is used, clearing of the activation source or DTCER is performed when the last of the chain of data transfers is executed. SCI, RSPI, RCAN-ET, SCIF, IIC3, USB and A/D converter interrupt/activation sources, on the other hand, are cleared when the DTC reads or writes to the relevant register during data transfer of the last of the chain.

Therefore, when the DTC is activated by an interrupt or activation source, if a read/write of the relevant register is not included in the last chained data transfer, the interrupt or activation source will be retained.

### 8.9.5 Transfer Information Start Address, Source Address, and Destination Address

The transfer information start address to be specified in the vector table should be address 4n. Transfer information should be placed in on-chip RAM or external memory space.

### 8.9.6 Access to DTC Registers through DTC

Do not access the DMAC or DTC registers by using DTC operation. Do not access the DTC registers by using DMAC operation.

### 8.9.7 Notes on IRQ Interrupt as DTC Activation Source

When a low level on the IRQ pin is to be detected, if the end of DTC transfer is used to request an interrupt to the CPU (transfer counter = 0 or DISEL = 1), the IRQ signal must be held low until the CPU accepts the interrupt.

### 8.9.8 Note on SCI or SCIF as DTC Activation Sources

When the TXI interrupt from the SCI is specified as a DTC activation source, the TEND flag in the SCI must not be used as the transfer end flag.

When the TXIF interrupt from the SCIF is specified as a DTC activation source, the TEND flag in the SCIF must not be used as the transfer end flag.

### 8.9.9 Clearing Interrupt Source Flag

The interrupt source flag set when the DTC transfer is completed should be cleared in the interrupt handler in the same way as for general interrupt source flags. For details, refer to section 6.10, Usage Note.

### 8.9.10 Conflict between NMI Interrupt and DTC Activation

When a conflict occurs between the generation of the NMI interrupt and the DTC activation, the NMI interrupt has priority. Thus the ERR bit is set to 1 and the DTC is not activated.

It takes  $3B\phi + 2P\phi$  for checking DTC stop by the NMI,  $3B\phi + 2P\phi$  for checking DTC activation by the IRQ, and  $1B\phi + 1P\phi$  to  $4B\phi + 1P\phi$  for checking DTC activation by the peripheral module.

### 8.9.11 Note on USB as DTC Activation Sources

To generate a CPU interrupt when a DTC transfer activated by the USB is completed, refer to the procedure described in section 24, USB Function Module (USB).

### 8.9.12 Operation when a DTC Activation Request has been Cancelled

Once DTC has accepted an activation request, the next activation request will not be accepted until the sequence of the DTC transaction has finished up to the end of write-back.

### 8.9.13 Note on Writing to DTCER

When the same condition has been set as both a DTC activation source and a CPU interrupt source, if the interrupt as both sources is generated while DTCER is also set for the DTC activation source, the DTC and CPU may be activated at the same time. Determine the value of DTCER before allowing the generation of DTC activation interrupts.

## Section 9 Bus State Controller (BSC)

The bus state controller (BSC) outputs control signals for various types of memory that is connected to the external address space and external devices. BSC functions enable this LSI to connect directly with SRAM, SDRAM, and other memory storage devices, and external devices.

### 9.1 Features

The BSC has the following features.

1. External address space
  - A maximum of 64 Mbytes for each of areas CS0 to CS7.
  - Can specify the normal space interface, SRAM interface with byte selection, burst ROM (clock synchronous or asynchronous), MPX-I/O, and SDRAM for each address space.
  - Can select the data bus width (8, 16, or 32 bits) for each address space.
  - Controls insertion of wait cycles for each address space.
  - Controls insertion of wait cycles for each read access and write access.
  - Can set independent idle cycles during the continuous access for five cases: read-write (in same space/different spaces), read-read (in same space/different spaces), the first cycle is a write access.
2. Normal space interface
  - Supports the interface that can directly connect to the SRAM.
3. Burst ROM interface (clock asynchronous)
  - High-speed access to the ROM that has the page mode function.
4. MPX-I/O interface
  - Can directly connect to a peripheral LSI that needs an address/data multiplexing.
5. SDRAM interface
  - Can set the SDRAM in up to two areas.
  - Multiplex output for row address/column address.
  - Efficient access by single read/single write.
  - High-speed access in bank-active mode.
  - Supports an auto-refresh and self-refresh.
  - Supports low-frequency and power-down modes.
  - Issues MRS and EMRS commands.

6. SRAM interface with byte selection
  - Can connect directly to a SRAM with byte selection.
7. Burst ROM interface (clock synchronous)
  - Can connect directly to a ROM of the clock-synchronous type.
8. Bus arbitration
  - Shares all of the resources with other CPU and outputs the bus enable after receiving the bus request from external devices.
9. Refresh function
  - Supports the auto-refresh and self-refresh functions.
  - Specifies the refresh interval using the refresh counter and clock selection.
  - Can execute concentrated refresh by specifying the refresh counts (1, 2, 4, 6, or 8).
10. Usage as interval timer for refresh counter
  - Generates an interrupt request at compare match.

Figure 9.1 shows a block diagram of the BSC.

Figure 9.1 Block Diagram of BSC

## 9.2 Input/Output Pins

Table 9.1 shows the pin configuration of the BSC.

**Table 9.1 Pin Configuration**

| Name                                 | I/O    | Function                                                                                                                                                                                                      |
|--------------------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A25 to A0                            | Output | Address bus                                                                                                                                                                                                   |
| D31 to D0                            | I/O    | Data bus                                                                                                                                                                                                      |
| $\overline{BS}$                      | Output | Bus cycle start                                                                                                                                                                                               |
| $\overline{CS0}$ to $\overline{CS7}$ | Output | Chip select                                                                                                                                                                                                   |
| $RD/\overline{WR}$                   | Output | Read/write<br>Connects to $\overline{WE}$ pins when SDRAM or SRAM with byte selection is connected.                                                                                                           |
| $\overline{RD}$                      | Output | Read pulse signal (read data output enable signal)<br>Functions as a strobe signal for indicating memory read cycles when PCMCIA is used.                                                                     |
| $\overline{AH}$                      | Output | A signal used to hold an address when MPX-I/O is in use                                                                                                                                                       |
| $WRHH/DQM_{UU}$                      | Output | Indicates that D31 to D24 are being written to.<br>Connected to the byte select signal when SRAM with byte selection is connected.<br>Functions as the select signals for D31 to D24 when SDRAM is connected. |
| $WRHL/DQM_{UL}$                      | Output | Indicates that D23 to D26 are being written to.<br>Connected to the byte select signal when SRAM with byte selection is connected.<br>Functions as the select signals for D23 to D26 when SDRAM is connected. |
| $WRH/DQMLU$                          | Output | Indicates that D15 to D8 are being written to.<br>Connected to the byte select signal when a SRAM with byte selection is connected.<br>Functions as the select signals for D15 to D8 when SDRAM is connected. |

| Name       | I/O    | Function                                                                                                                                                                                                    |
|------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WRL/DQMLL  | Output | Indicates that D7 to D0 are being written to.<br>Connected to the byte select signal when a SRAM with byte selection is connected.<br>Functions as the select signals for D7 to D0 when SDRAM is connected. |
| RASL, RASU | Output | Connected to $\overline{\text{RAS}}$ pin when SDRAM is connected.                                                                                                                                           |
| CASL, CASU | Output | Connected to $\overline{\text{CAS}}$ pin when SDRAM is connected.                                                                                                                                           |
| CKE        | Output | Connected to CKE pin when SDRAM is connected.                                                                                                                                                               |
| WAIT       | Input  | External wait input                                                                                                                                                                                         |
| BREQ       | Input  | Bus request input                                                                                                                                                                                           |
| BACK       | Output | Bus enable output                                                                                                                                                                                           |
| REFOUT     | Output | Refresh request output in bus-released state                                                                                                                                                                |
| MD0        | Input  | Selects bus width (16 or 32 bits) of area 0.<br>It also selects the on-chip ROM enabled or disabled mode and external bus access enabled or disabled mode.                                                  |

## 9.3 Area Overview

### 9.3.1 Address Map

In the architecture, this LSI has a 32-bit address space, which is divided into external address space and on-chip spaces (on-chip ROM, on-chip RAM, on-chip peripheral modules, and reserved areas) according to the upper bits of the address.

The kind of memory to be connected and the data bus width are specified in each partial space. The address map for the external address space is listed below.

**Table 9.2 Address Map in On-Chip ROM-Enabled Mode**

| Address                    | Space       | Memory to be Connected                                                             | Size                                                                                                    |
|----------------------------|-------------|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| H'0000 0000 to H'000F FFFF | On-chip ROM | On-chip ROM                                                                        | 512 kbytes<br>(SH72165, SH72145),<br>768 kbytes<br>(SH72166, SH72146),<br>1 Mbyte<br>(SH72167, SH72147) |
| H'0070 0000 to H'01FF FFFF | Other       | Reserved area                                                                      | —                                                                                                       |
| H'0200 0000 to H'03FF FFFF | CS0         | Normal space, SRAM with byte selection,<br>burst ROM (asynchronous or synchronous) | 32 Mbytes                                                                                               |
| H'0400 0000 to H'07FF FFFF | CS1         | Normal space, SRAM with byte selection                                             | 64 Mbytes                                                                                               |
| H'0800 0000 to H'0BFF FFFF | CS2         | Normal space, SRAM with byte selection, SDRAM                                      | 64 Mbytes                                                                                               |
| H'0C00 0000 to H'0FFF FFFF | CS3         | Normal space, SRAM with byte selection, SDRAM                                      | 64 Mbytes                                                                                               |
| H'1000 0000 to H'13FF FFFF | CS4         | Normal space, SRAM with byte selection,<br>burst ROM (asynchronous)                | 64 Mbytes                                                                                               |
| H'1400 0000 to H'17FF FFFF | CS5         | Normal space, SRAM with byte selection, MPX-I/O                                    | 64 Mbytes                                                                                               |
| H'1800 0000 to H'1BFF FFFF | CS6         | Normal space, SRAM with byte selection                                             | 64 Mbytes                                                                                               |
| H'1C00 0000 to H'1FFF FFFF | CS7         | Normal space, SRAM with byte selection                                             | 64 Mbytes                                                                                               |
| H'2000 0000 to H'FFF7 FFFF | Other       | Reserved area                                                                      | —                                                                                                       |
| H'FFF8 0000 to H'FFFB FFFF | Other       | On-chip RAM, reserved area*                                                        | —                                                                                                       |
| H'FFFC 0000 to H'FFFF FFFF | Other       | On-chip peripheral modules, reserved area*                                         | —                                                                                                       |

Note: \* For the on-chip RAM space, access the addresses shown in section 29, On-Chip RAM. For the on-chip peripheral module space, access the addresses shown in section 32, List of Registers. Do not access addresses which are not described in these sections. Otherwise, the correct operation cannot be guaranteed.

**Table 9.3 Address Map in On-Chip ROM-Disabled Mode**

| Address                    | Space | Memory to be Connected                                                          | Size      |
|----------------------------|-------|---------------------------------------------------------------------------------|-----------|
| H'0000 0000 to H'03FF FFFF | CS0   | Normal space, SRAM with byte selection, burst ROM (asynchronous or synchronous) | 64 Mbytes |
| H'0400 0000 to H'07FF FFFF | CS1   | Normal space, SRAM with byte selection                                          | 64 Mbytes |
| H'0800 0000 to H'0BFF FFFF | CS2   | Normal space, SRAM with byte selection, SDRAM                                   | 64 Mbytes |
| H'0C00 0000 to H'0FFF FFFF | CS3   | Normal space, SRAM with byte selection, SDRAM                                   | 64 Mbytes |
| H'1000 0000 to H'13FF FFFF | CS4   | Normal space, SRAM with byte selection, burst ROM (asynchronous)                | 64 Mbytes |
| H'1400 0000 to H'17FF FFFF | CS5   | Normal space, SRAM with byte selection, MPX-I/O                                 | 64 Mbytes |
| H'1800 0000 to H'1BFF FFFF | CS6   | Normal space, SRAM with byte selection                                          | 64 Mbytes |
| H'1C00 0000 to H'1FFF FFFF | CS7   | Normal space, SRAM with byte selection                                          | 64 Mbytes |
| H'2000 0000 to H'FFF7 FFFF | Other | Reserved area                                                                   | —         |
| H'FFF8 0000 to H'FFFB FFFF | Other | On-chip RAM, reserved area*                                                     | —         |
| H'FFFC 0000 to H'FFFF FFFF | Other | On-chip peripheral modules, reserved area*                                      | —         |

Note: \* For the on-chip RAM space, access the addresses shown in section 29, On-Chip RAM. For the on-chip I/O register space, access the addresses shown in section 32, List of Registers. Do not access addresses which are not described in these sections. Otherwise, the correct operation cannot be guaranteed.

### 9.3.2 Setting Operating Modes

This LSI can set the following modes of operation at the time of power-on reset using the external pins.

- Single-Chip Mode/External Bus Accessible Mode

In single-chip mode, no access is made to the external bus, and the LSI is activated by the on-chip ROM program upon a power-on reset. The BSC module enters the module standby state to reduce power consumption.

The address, data, bus control pins used in external bus accessible mode can be used as the port function pins in single-chip mode.

- On-Chip ROM-Enabled Mode/On-Chip ROM-Disabled Mode

In on-chip ROM-enabled mode, since the first half of area 0 is allocated to the on-chip ROM, the LSI can be activated by the on-chip ROM program upon a power-on reset. The second half of area 0 is the external memory space.

In on-chip ROM-disabled mode, the LSI is activated by the program stored in the external memory allocated to area 0. The second half of area 0 is the external memory space. In this case, a ROM is assumed for the external memory of area 0. Therefore, minimum functions are provided for the pins including address bus, data bus, CS0, and RD. Although  $\overline{BS}$ , RD/ $\overline{WR}$ ,  $\overline{WRxx}$ , and other pins are shown in the examples of access waveforms in this section, these are examples when pin settings are performed by the pin function controller. For details, see section 22, Pin Function Controller (PFC). Do not perform any operation except for area 0 read access until the pin settings by the program is completed.

- Initial Settings of Data Bus Widths for Areas 0 to 7

The initial settings of data bus widths of areas 0 to 7 can be selected at a time as 16 bits or 32 bits.

In on-chip ROM-disabled mode, the data bus width of area 0 cannot be changed from its initial setting after a power-on reset, but the data bus widths of areas 1 to 7 can be changed by register settings in the program. In on-chip ROM-enabled mode, all the data bus widths of areas 0 to 7 can be changed by register settings in the program. Note that data bus widths will be restricted depending on memory types.

- Initial Settings of Big Endian / Little Endian

The initial settings of byte-data alignment of areas 1 to 7 can be selected as big endian or little endian. In on-chip ROM-disabled mode, the endianness of area 0 cannot be changed from its initial setting after a power-on reset, but the endianness of areas 1 to 7 can be changed by register settings in the program. In on-chip ROM-enabled mode, all the endianness of areas 1 to 7 can be changed by register settings in the program. Area 0 cannot be selected as little endian. Since the instruction fetch is mixed with the 32- and 16-bit access and the allocation to the little endian area is difficult, the instruction must be executed within the big endian area.

For details of mode settings, see section 3, MCU Operating Modes.

## 9.4 Register Descriptions

The BSC has the following registers.

Do not access spaces other than area 0 until settings of the connected memory interface are completed.

**Table 9.4 Register Configuration**

| Register Name                         | Abbreviation | R/W | Initial Value | Address                       | Access Size |
|---------------------------------------|--------------|-----|---------------|-------------------------------|-------------|
| Common control register               | CMNCR        | R/W | H'00001010    | H'FFFC0000                    | 32          |
| CSn space bus control register        | CSnBCR       | R/W | H'36DB0400*   | H'FFFC 0004 to<br>H'FFFC 0020 | 32          |
| CSn space wait control register       | CSnWCR       | R/W | H'00000500    | H'FFFC0028 to<br>H'FFFC 0044  | 32          |
| SDRAM control register                | SDCR         | R/W | H'00000000    | H'FFFC004C                    | 32          |
| Refresh timer control/status register | RTCSR        | R/W | H'00000000    | H'FFFC0050                    | 32          |
| Refresh timer counter                 | RTCNT        | R/W | H'00000000    | H'FFFC0054                    | 32          |
| Refresh time constant register        | RTCOR        | R/W | H'00000000    | H'FFFC0058                    | 32          |
| Bus function extending register       | BSCEHR       | R/W | H'0000        | H'FFFE3C1A                    | 16          |

Note: \* Value when selecting the 16-bit bus width with the external pin (MD0). When selecting the 32-bit bus width, the initial value will be H'36DB 0600.

### 9.4.1 Common Control Register (CMNCR)

CMNCR is a 32-bit register that controls the common items for each area. This register is initialized to H'00001010 by a power-on reset and retains the value by a manual reset and in software standby mode.

### 9.4.2 CSn Space Bus Control Register (CSnBCR) (n = 0 to 7)

CSnBCR is a 32-bit readable/writable register that specifies the type of memory connected to a space, data bus width of an area, endian, and the number of waits between access cycles. This register is initialized to H'36DB0x00 by a power-on reset and retains the value by a manual reset and in software standby mode.

Do not access external memory other than area 0 until CSnBCR initial setting is completed.

Idle cycles may be inserted even when they are not specified. For details, see section 9.5.10, Wait between Access Cycles.

Note: \* Details of Initial value of this bit are shown below according to the MCU operating mode.

Initial value in mode 0: B'11

Initial value in mode 1: B'10

Initial value in mode 2: B'01

Initial value in mode 3: B'00

### 9.4.3 CSn Space Wait Control Register (CSnWCR) (n = 0 to 7)

CSnWCR specifies various wait cycles for memory access. The bit configuration of this register varies as shown below according to the memory type (TYPE2 to TYPE0) specified by the CSn space bus control register (CSnBCR). Specify CSnWCR before accessing the target area. Specify CSnBCR first, then specify CSnWCR.

CSnWCR is initialized to H'00000500 by a power-on reset and retains the value by a manual reset and in software standby mode.

#### (1) Normal Space, SRAM with Byte Selection, MPX-I/O

- CS0WCR

### 9.4.4 SDRAM Control Register (SDCR)

SDCR specifies the method to refresh and access SDRAM, and the types of SDRAMs to be connected.

SDCR is initialized to H'00000000 by a power-on reset and retains the value by a manual reset and in software standby mode.

### 9.4.5 Refresh Timer Control/Status Register (RTCSR)

RTCSR specifies various items about refresh for SDRAM. RTCSR is initialized to H'00000000 by a power-on reset and retains the value by a manual reset and in software standby mode.

When RTCSR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection.

The phase of the clock for incrementing the count in the refresh timer counter (RTCNT) is adjusted only by a power-on reset. Note that there is an error in the time until the compare match flag is set for the first time after the timer is started with the CKS[2:0] bits being set to a value other than B'000.

RTCNT is an 8-bit counter that increments using the clock selected by bits CKS[2:0] in RTCSR. When RTCNT matches RTCOR, RTCNT is cleared to 0. The value in RTCNT returns to 0 after counting up to 255. When the RTCNT is written, the upper 16 bits of the write data must be H'A55A to cancel write protection. This counter is initialized to H'00000000 by a power-on reset and retains the value by a manual reset and in software standby mode.

### 9.4.7 Refresh Time Constant Register (RTCOR)

RTCOR is an 8-bit register. When RTCOR matches RTCNT, the CMF bit in RTCSR is set to 1 and RTCNT is cleared to 0.

When the RFSH bit in SDCR is 1, a memory refresh request is issued by this matching signal. This request is maintained until the refresh operation is performed. If the request is not processed when the next matching occurs, the previous request is ignored.

The  $\overline{\text{REFOUT}}$  signal can be asserted when a refresh request is generated while the bus is released. For details, see the description of Relationship between Refresh Requests and Bus Cycles in section 9.5.6 (9), Relationship between Refresh Requests and Bus Cycles, and section 9.5.11, Bus Arbitration.

When the CMIE bit in RTCSR is set to 1, an interrupt request is issued by this matching signal. The request continues to be output until the CMF bit in RTCSR is cleared. Clearing the CMF bit only affects the interrupt request and does not clear the refresh request. Therefore, a combination of refresh request and interval timer interrupt can be specified so that the number of refresh requests are counted by using timer interrupts while refresh is performed periodically.

When RTCOR is written, the upper 16 bits of the write data must be H'A55A to cancel write protection. This register is initialized to H'00000000 by a power-on reset and retains the value by a manual reset and in software standby mode.

## 9.4.8 Bus Function Extending Register (BSCEHR)

BSCEHR is a 16-bit register that specifies the timing of DTC or DMAC bus release. It is used to give priority to DTC or DMAC transfer or reduce the number of cycles in which the DTC is active.

For the differences in DTC operation according to the combinations of the DTLOCK and DTBST bit settings, refer to section 8.5.9, DTC Bus Release Timing.

Setting the DTSA bit enables DTC short address mode. For details of the short address mode, see section 8.4, Location of Transfer Information and DTC Vector Table.

The DTPR bit selects the DTC activation priority used when multiple DTC activation requests are generated before DTC activation.

Do not modify this register while the DMAC or DTC is active.

## 9.5 Operation

### 9.5.1 Endian/Access Size and Data Alignment

This LSI supports big endian in which the 0 address is the most significant byte (MSB), and little endian in which the 0 address is the least significant byte (LSB) in the byte data. In a space of areas 1 to 7, endian can be set by the CSnBCR setting while the target space is not accessed. In a space of area 0, the CSnBCR setting is invalid in on-chip ROM-disabled mode. In on-chip ROM-enabled mode, endian can be set by the CSnBCR setting in a space of areas 0 to 7.

For normal memory and SRAM with byte selection, the data bus width can be selected from three widths (8, 16, and 32 bits). For SDRAM, the data bus width can be selected from two widths (16 and 32 bits). For MPX-I/O, the data bus width is fixed at 8 bits or 16 bits, or 8 bits or 16 bits can be selected by the access address. Data alignment is performed in accordance with the data bus width of the device. This also means that when longword data is read from a byte-width device, the read operation must be done four times. In this LSI, data alignment and conversion of data length is performed automatically between the respective interfaces.

Tables 9.5 to 9.10 show the relationship between device data width and access unit. Note that addresses corresponding to the strobe signals for the 16-bit bus width differ between big endian and little endian.  $\overline{\text{WRH}}$  indicates the 0 address in big-endian mode, but  $\overline{\text{WRL}}$  indicates the 0 address in little-endian mode.

Area 0 cannot be selected as little endian. Since the instruction fetch is mixed with the 32- and 16-bit access and the allocation to the little endian area is difficult, the instruction must be executed within the big endian area.

**Table 9.5 32-Bit External Device Access and Data Alignment in Big-Endian Mode**

## 9.5.2 Normal Space Interface

### (1) Basic Timing

For access to a normal space, this LSI uses strobe signal output in consideration of the fact that mainly static RAM will be directly connected. When using SRAM with a byte-selection pin, see section 9.5.8, SRAM Interface with Byte Selection. Figure 9.2 shows the basic timings of normal space access. A no-wait normal access is completed in two cycles. The  $\overline{\text{BS}}$  signal is asserted for one cycle to indicate the start of a bus cycle.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.2 Normal Space Basic Access Timing (Access Wait 0)**

There is no access size specification when reading. The correct access start address is output in the least significant bit of the address, but since there is no access size specification, 16 bits are always read in case of a 16-bit device. When writing, only the  $\overline{WRxx}$  signal for the byte to be written is asserted.

It is necessary to output the data that has been read using  $\overline{RD}$  when a buffer is established in the data bus. The  $\overline{RD}/\overline{WR}$  signal is in a read state (high output) when no access has been carried out. Therefore, care must be taken when controlling the external data buffer, to avoid collision.

Figures 9.3 and 9.4 show the basic timings of normal space access. If the WM bit in CSnWCR is cleared to 0, a Tnop cycle is inserted after the CSn space access to evaluate the external wait (figure 9.3). If the WM bit in CSnWCR is set to 1, external waits are ignored and no Tnop cycle is inserted (figure 9.4).

**Figure 9.3 Continuous Access for Normal Space 1**  
**Bus Width = 16 Bits, Longword Access, CSnWCR.WM Bit = 0**  
**(Access Wait = 0, Cycle Wait = 0)**

Note: \* The waveform for  $\overline{DACKn}$  is when active low is specified.

**Figure 9.4 Continuous Access for Normal Space 2**  
**Bus Width = 16 Bits, Longword Access,  $\overline{CSnWCR.WM}$  Bit = 1**  
**(Access Wait = 0, Cycle Wait = 0)**

**Figure 9.5 Example of 32-Bit Data-Width SRAM Connection**

**Figure 9.6 Example of 16-Bit Data-Width SRAM Connection**

**Figure 9.7 Example of 8-Bit Data-Width SRAM Connection**

### 9.5.3 Access Wait Control

Wait cycle insertion on a normal space access can be controlled by the settings of bits WR3 to WR0 in CSnWCR. It is possible for areas 1, 4, 5, and 7 to insert wait cycles independently in read access and in write access. Areas 0, 2, 3, and 6 have common access wait for read cycle and write cycle. The specified number of  $T_w$  cycles are inserted as wait cycles in a normal space access shown in figure 9.8.

**Figure 9.8 Wait Timing for Normal Space Access (Software Wait Only)**

When the WM bit in CSnWCR is cleared to 0, the external wait input  $\overline{\text{WAIT}}$  signal is also sampled.  $\overline{\text{WAIT}}$  pin sampling is shown in figure 9.9. A 2-cycle wait is specified as a software wait. The  $\overline{\text{WAIT}}$  signal is sampled on the falling edge of CK at the transition from the T1 or Tw cycle to the T2 cycle.

**Figure 9.9 Wait Cycle Timing for Normal Space Access  
(Wait Cycle Insertion Using  $\overline{\text{WAIT}}$  Signal)**

### 9.5.4 $\overline{\text{CSn}}$ Assert Period Expansion

The number of cycles from  $\overline{\text{CSn}}$  assertion to  $\overline{\text{RD}}$ ,  $\overline{\text{WRxx}}$  assertion can be specified by setting bits SW1 and SW0 in CSnWCR. The number of cycles from  $\overline{\text{RD}}$ ,  $\overline{\text{WRxx}}$  negation to  $\overline{\text{CSn}}$  negation can be specified by setting bits HW1 and HW0. Therefore, a flexible interface to an external device can be obtained. Figure 9.10 shows an example. A  $T_h$  cycle and a  $T_f$  cycle are added before and after an ordinary cycle, respectively. In these cycles,  $\overline{\text{RD}}$  and  $\overline{\text{WRxx}}$  are not asserted, while other signals are asserted. The data output is prolonged to the  $T_f$  cycle, and this prolongation is useful for devices with slow writing operations.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.10  $\overline{\text{CSn}}$  Assert Period Expansion**

### 9.5.5 MPX-I/O Interface

Access timing for the MPX space is shown below. In the MPX space,  $\overline{CS5}$ ,  $\overline{AH}$ ,  $\overline{RD}$ , and  $\overline{WRxx}$  signals control the accessing. The basic access for the MPX space consists of 2 cycles of address output followed by an access to a normal space. The bus width for the address output cycle or the data input/output cycle is fixed to 8 bits or 16 bits. Alternatively, it can be 8 bits or 16 bits depending on the address to be accessed.

Output of the addresses D15 to D0 or D7 to D0 is performed from cycle Ta2 to cycle Ta3. Because cycle Ta1 has a high-impedance state, collisions of addresses and data can be avoided without inserting idle cycles, even in continuous access cycles. Address output is increased to 3 cycles by setting the MPXW bit in CS5WCR to 1.

The  $\overline{RD}/\overline{WR}$  signal is output at the same time as the  $\overline{CS5}$  signal; it is high in the read cycle and low in the write cycle.

The data cycle is the same as that in a normal space access.

The delay cycles the number of which is specified by SW[1:0] are inserted between cycle Ta3 and cycle T1. The delay cycles the number of which is specified by HW[1:0] are added after cycle T2.

Timing charts are shown in figures 9.11 to 9.14.

## 9.5.6 SDRAM Interface

### (1) SDRAM Direct Connection

The SDRAM that can be connected to this LSI is a product that has 11/12/13 bits of row address, 8/9/10 bits of column address, 4 or less banks, and uses the A10 pin for setting precharge mode in read and write command cycles.

The control signals for direct connection of SDRAM are  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASL}}$ ,  $\overline{\text{CASU}}$ ,  $\text{RD}/\overline{\text{WR}}$ ,  $\text{DQM}\overline{\text{UU}}$ ,  $\text{DQM}\overline{\text{UL}}$ ,  $\text{DQM}\overline{\text{LU}}$ ,  $\text{DQM}\overline{\text{LL}}$ ,  $\text{CKE}$ ,  $\overline{\text{CS2}}$ , and  $\overline{\text{CS3}}$ . All the signals other than  $\overline{\text{CS2}}$  and  $\overline{\text{CS3}}$  are common to all areas, and signals other than  $\text{CKE}$  are valid when  $\overline{\text{CS2}}$  or  $\overline{\text{CS3}}$  is asserted. SDRAM can be connected to up to 2 spaces. The data bus width of the area that is connected to SDRAM can be set to 32 bits or 16 bits.

Burst read/single write (burst length 1) and burst read/burst write (burst length 1) are supported as SDRAM operating mode.

Commands for SDRAM can be specified by  $\overline{\text{RASL}}$ ,  $\overline{\text{CASL}}$ ,  $\text{RD}/\overline{\text{WR}}$ , and specific address signals. These commands supports:

- NOP
- Auto-refresh (REF)
- Self-refresh (SELF)
- All banks pre-charge (PALL)
- Specified bank pre-charge (PRE)
- Bank active (ACTV)
- Read (READ)
- Read with pre-charge (READA)
- Write (WRIT)
- Write with pre-charge (WRITA)
- Write mode register (MRS, EMRS)

The byte to be accessed is specified by  $\text{DQM}\overline{\text{UU}}$ ,  $\text{DQM}\overline{\text{UL}}$ ,  $\text{DQM}\overline{\text{LU}}$ , and  $\text{DQM}\overline{\text{LL}}$ . Reading or writing is performed for a byte whose corresponding  $\text{DQMxx}$  is low. For details on the relationship between  $\text{DQMxx}$  and the byte to be accessed, see section 9.5.1, Endian/Access Size and Data Alignment.

Figures 9.15 to 9.17 show examples of the connection of the SDRAM with the LSI.

As shown in figure 9.17, two sets of SDRAMs of 32Mbytes or smaller can be connected to the same CS space by using  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ , and  $\overline{\text{CASL}}$ . In this case, a total of 8 banks are assigned to the same CS space: 4 banks specified by  $\overline{\text{RASL}}$  and  $\overline{\text{CASL}}$ , and 4 banks specified by  $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$ . When accessing the address with A25 = 0,  $\overline{\text{RASL}}$  and  $\overline{\text{CASL}}$  are asserted. When accessing the address with A25 = 1,  $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$  are asserted.

**Figure 9.15 Example of 32-Bit Data Width SDRAM Connection**  
( $\overline{\text{RASU}}$  and  $\overline{\text{CASU}}$  are Not Used)

**Figure 9.16 Example of 16-Bit Data Width SDRAM Connection  
( $\overline{RASU}$  and  $\overline{CASU}$  are Used)**

**Figure 9.17 Example of 16-Bit Data Width SDRAM Connection**

## (2) Address Multiplexing

An address multiplexing is specified so that SDRAM can be connected without external multiplexing circuitry according to the setting of bits BSZ[1:0] in CSnBCR, bits A2ROW[1:0], and A2COL[1:0], A3ROW[1:0], and A3COL[1:0] in SDCR. Tables 9.11 to 9.16 show the relationship between the settings of bits BSZ[1:0], A2ROW[1:0], A2COL[1:0], A3ROW[1:0], and A3COL[1:0] and the bits output at the address pins. Do not specify those bits in the manner other than this table, otherwise the operation of this LSI is not guaranteed. A29 to A18 are not multiplexed and the original values of address are always output at these pins.

The A0 pin of SDRAM specifies a word address. Therefore, connect the A0 pin of SDRAM to the A1 pin of the LSI; then connect the A1 pin of SDRAM to the A2 pin of the LSI, and so on.

**Table 9.11 Relationship between BSZ[1:0], A2/3ROW[1:0], A2/3COL[1:0], and Address Multiplex Output (1)-1**

| Setting                   |                             |                                |           |                                |
|---------------------------|-----------------------------|--------------------------------|-----------|--------------------------------|
| BSZ<br>[1:0]              | A2/3<br>ROW<br>[1:0]        | A2/3<br>COL<br>[1:0]           |           |                                |
| 11 (32 Bits)              | 00 (11 Bits)                | 00 (8 Bits)                    |           |                                |
| Output Pin of<br>This LSI | Row Address<br>Output Cycle | Column Address<br>Output Cycle | SDRAM Pin | Function                       |
| A17                       | A25                         | A17                            |           | Unused                         |
| A16                       | A24                         | A16                            |           |                                |
| A15                       | A23                         | A15                            |           |                                |
| A14                       | A22* <sup>2</sup>           | A22* <sup>2</sup>              | A12(BA1)  | Specifies bank                 |
| A13                       | A21* <sup>2</sup>           | A21* <sup>2</sup>              | A11(BA0)  |                                |
| A12                       | A20                         | L/H* <sup>1</sup>              | A10/AP    | Specifies<br>address/precharge |
| A11                       | A19                         | A11                            | A9        | Address                        |
| A10                       | A18                         | A10                            | A8        |                                |
| A9                        | A17                         | A9                             | A7        |                                |
| A8                        | A16                         | A8                             | A6        |                                |
| A7                        | A15                         | A7                             | A5        |                                |
| A6                        | A14                         | A6                             | A4        |                                |
| A5                        | A13                         | A5                             | A3        |                                |
| A4                        | A12                         | A4                             | A2        |                                |
| A3                        | A11                         | A3                             | A1        |                                |
| A2                        | A10                         | A2                             | A0        |                                |
| A1                        | A9                          | A1                             |           |                                |
| A0                        | A8                          | A0                             |           |                                |

Example of connected memory

64-Mbit product (512 Kwords × 32 bits × 4 banks, column 8 bits product): 1

16-Mbit product (512 Kwords × 16 bits × 2 banks, column 8 bits product): 2

Notes: 1. L/H is a bit used in the command specification; it is fixed at low or high according to the access mode.

2. Bank address specification

Example of connected memory

128-Mbit product (2 Mwords × 16 bits × 4 banks, column 9 bits product): 1

Notes: 1. L/H is a bit used in the command specification; it is fixed at low or high according to the access mode.

2. Bank address specification

Example of connected memory

512-Mbit product (8 Mwords × 16 bits × 4 banks, column 10 bits product): 1

Notes: 1. L/H is a bit used in the command specification; it is fixed at low or high according to the access mode.

2. Bank address specification

3. Only the  $\overline{\text{RASL}}$  pin is asserted because the A25 pin specified the bank address.  $\overline{\text{RASU}}$  is not asserted.

### (3) Burst Read

A burst read occurs in the following cases with this LSI.

- Access size in reading is larger than data bus width.
- 16-byte transfer in DMAC

This LSI always accesses the SDRAM with burst length 1. For example, read access of burst length 1 is performed consecutively 8 times to read 16-byte continuous data from the SDRAM that is connected to a 16-bit data bus. This access is called the burst read with the burst number 8.

Table 9.17 shows the relationship between the access size and the number of bursts.

**Table 9.17 Relationship between Access Size and Number of Bursts**

| Bus Width | Access Size | Number of Bursts |
|-----------|-------------|------------------|
| 16 bits   | 8 bits      | 1                |
|           | 16 bits     | 1                |
|           | 32 bits     | 2                |
|           | 16 bytes    | 8                |
| 32 bits   | 8 bits      | 1                |
|           | 16 bits     | 1                |
|           | 32 bits     | 1                |
|           | 16 bytes    | 4                |

Figures 9.18 and 9.19 show a timing chart in burst read. In burst read, an ACTV command is output in the Tr cycle, the READ command is issued in the Tc1, Tc2, and Tc3 cycles, the READA command is issued in the Tc4 cycle, and the read data is received at the rising edge of the external clock (CK) in the Td1 to Td4 cycles. The Tap cycle is used to wait for the completion of an auto-precharge induced by the READA command in the SDRAM. In the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.

In this LSI, wait cycles can be inserted by specifying each bit in CS3WCR to connect the SDRAM in variable frequencies. Figure 9.19 shows an example in which wait cycles are inserted. The number of cycles from the Tr cycle where the ACTV command is output to the Tc1 cycle where the READ command is output can be specified using the WTRCD1 and WTRCD0 bits in CS3WCR. If the WTRCD1 and WTRCD0 bits specify one cycles or more, a Trw cycle where the NOT command is issued is inserted between the Tr cycle and Tc1 cycle. The number of cycles

from the Tc1 cycle where the READ command is output to the Td1 cycle where the read data is latched can be specified for the CS2 and CS3 spaces independently, using the A2CL1 and A2CL0 bits in CS2WCR or the A3CL1 and A3CL0 bits in CS3WCR and WTRCD0 bit in CS3WCR. The number of cycles from Tc1 to Td1 corresponds to the SDRAM CAS latency. The CAS latency for the SDRAM is normally defined as up to three cycles. However, the CAS latency in this LSI can be specified as 1 to 4 cycles. This CAS latency can be achieved by connecting a latch circuit between this LSI and the SDRAM.

A Tde cycle is an idle cycle required to transfer the read data into this LSI and occurs once for every burst read or every single read.

- Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACKn is when active low is specified.

**Figure 9.18 Burst Read Basic Timing (CAS Latency 1, Auto-Precharge)**

**Figure 9.19 Burst Read Wait Specification Timing (CAS Latency 2,  
WTRCD[1:0] = 1 Cycle, Auto-Precharge)**

#### (4) Single Read

A read access ends in one cycle when the data bus width is larger than or equal to the access size. This, simply stated, is single read. As the SDRAM is set to the burst read with the burst length 1, only the required data is output. A read access that ends in one cycle is called single read.

Figure 9.20 shows the single read basic timing.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACKn is when active low is specified.

**Figure 9.20 Basic Timing for Single Read (CAS Latency 1, Auto-Precharge)**

## (5) Burst Write

A burst write occurs in the following cases in this LSI.

- Access size in writing is larger than data bus width.
- 16-byte transfer in DMAC

This LSI always accesses SDRAM with burst length 1. For example, write access of burst length 1 is performed continuously 8 times to write 16-byte continuous data to the SDRAM that is connected to a 16-bit data bus. This access is called burst write with the burst number 8.

The relationship between the access size and the number of bursts is shown in table 9.17.

Figure 9.21 shows a timing chart for burst writes. In burst write, an ACTV command is output in the Tr cycle, the WRIT command is issued in the Tc1, Tc2, and Tc3 cycles, and the WRITA command is issued to execute an auto-precharge in the Tc4 cycle. In the write cycle, the write data is output simultaneously with the write command. After the write command with the auto-precharge is output, the Trw1 cycle that waits for the auto-precharge initiation is followed by the Tap cycle that waits for completion of the auto-precharge induced by the WRITA command in the SDRAM. Between the Trw1 and the Tap cycle, a new command will not be issued to the same bank. However, access to another CS space or another bank in the same SDRAM space is enabled. The number of Trw1 cycles is specified by the TRWL1 and TRWL0 bits in CS3WCR. The number of Tap cycles is specified by the WTRP1 and WTRP0 bits in CS3WCR.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACKn is when active low is specified.

**Figure 9.21 Basic Timing for Burst Write (Auto-Precharge)**

## (6) Single Write

A write access ends in one cycle when the data bus width is larger than or equal to access size. As a single write or burst write with burst length 1 is set in SDRAM, only the required data is output. The write access that ends in one cycle is called single write. Figure 9.22 shows the single write basic timing.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACKn is when active low is specified.

**Figure 9.22 Single Write Basic Timing (Auto-Precharge)**

## (7) Bank Active

The SDRAM bank function can be used to support high-speed access to the same row address. When the BACTV bit in SDCR is 1, access is performed using commands without auto-precharge (READ or WRIT). This function is called bank-active function. This function is valid only for either the upper or lower bits of area 3. When area 3 is set to bank-active mode, area 2 should be set to normal space or SRAM with byte selection. When areas 2 and 3 are both set to SDRAM or both the upper and lower bits of area 3 are connected to SDRAM, auto-precharge mode must be set.

When the bank-active function is used, precharging is not performed when the access ends. When accessing the same row address in the same bank, it is possible to issue the READ or WRIT command immediately, without issuing an ACTV command. As SDRAM is internally divided into several banks, it is possible to activate one row address in each bank. If the next access is to a different row address, a PRE command is first issued to precharge the relevant bank, then when precharging is completed, the access is performed by issuing an ACTV command followed by a READ or WRIT command. If this is followed by an access to a different row address, the access time will be longer because of the precharging performed after the access request is issued. The number of cycles between issuance of the PRE command and the ACTV command is determined by the WTRP1 and WTPR0 bits in CS3WCR.

In a write, when an auto-precharge is performed, a command cannot be issued to the same bank for a period of  $Trwl + Tap$  cycles after issuance of the WRITA command. When bank active mode is used, READ or WRIT commands can be issued successively if the row address is the same. The number of cycles can thus be reduced by  $Trwl + Tap$  cycles for each write.

There is a limit on  $tRAS$ , the time for placing each bank in the active state. If there is no guarantee that there will not be a cache hit and another row address will be accessed within the period in which this value is maintained by program execution, it is necessary to set auto-refresh and set the refresh cycle to no more than the maximum value of  $tRAS$ .

A burst read cycle without auto-precharge is shown in figure 9.23, a burst read cycle for the same row address in figure 9.24, and a burst read cycle for different row addresses in figure 9.25. Similarly, a burst write cycle without auto-precharge is shown in figure 9.26, a burst write cycle for the same row address in figure 9.27, and a burst write cycle for different row addresses in figure 9.28.

In figure 9.24, a  $Tnop$  cycle in which no operation is performed is inserted before the  $Tc$  cycle that issues the READ command. The  $Tnop$  cycle is inserted to acquire two cycles of CAS latency for the  $DQMxx$  signal that specifies the read byte in the data read from the SDRAM. If the CAS

latency is specified as two cycles or more, the T<sub>nop</sub> cycle is not inserted because the two cycles of latency can be acquired even if the DQM<sub>xx</sub> signal is asserted after the T<sub>c</sub> cycle.

When bank active mode is set, if only access cycles to the respective banks in the area 3 space are considered, as long as access cycles to the same row address continue, the operation starts with the cycle in figure 9.23 or 9.26, followed by repetition of the cycle in figure 9.24 or 9.27. An access to a different area during this time has no effect. If there is an access to a different row address in the bank active state, after this is detected the bus cycle in figure 9.24 or 9.27 is executed instead of that in figure 9.25 or 9.28. In bank active mode, too, all banks become inactive after a refresh cycle or after the bus is released as the result of bus arbitration.

- Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
2. The waveform for DACK<sub>n</sub> is when active low is specified.

**Figure 9.23 Burst Read Timing (Bank Active, Different Bank, CAS Latency 1)**

**Figure 9.28 Single Write Timing (Bank Active, Different Row Addresses in the Same Bank)**

## (8) Refreshing

This LSI has a function for controlling SDRAM refreshing. Auto-refreshing can be performed by clearing the RMODE bit to 0 and setting the RFSH bit to 1 in SDCR. A continuous refreshing can be performed by setting the RRC2 to RRC0 bits in RTCSR. If SDRAM is not accessed for a long period, self-refresh mode, in which the power consumption for data retention is low, can be activated by setting both the RMODE bit and the RFSH bit to 1.

### (a) Auto-refreshing

Refreshing is performed at intervals determined by the input clock selected by bits CKS2 to CKS0 in RTCSR, and the value set by in RTCOR. The value of bits CKS2 to CKS0 in RTCOR should be set so as to satisfy the refresh interval stipulation for the SDRAM used. First make the settings for RTCOR, RTCNT, and the RMODE and RFSH bits in SDCR, then make the CKS2 to CKS0 and RRC2 to RRC0 settings. When the clock is selected by bits CKS2 to CKS0, RTCNT starts counting up from the value at that time. The RTCNT value is constantly compared with the RTCOR value, and if the two values are the same, a refresh request is generated and an auto-refresh is performed for the number of times specified by the RRC2 to RRC0. At the same time, RTCNT is cleared to zero and the count-up is restarted.

Figure 9.29 shows the auto-refresh cycle timing. After starting, the auto refreshing, PALL command is issued in the  $T_p$  cycle to make all the banks to pre-charged state from active state when some bank is being pre-charged. Then REF command is issued in the  $T_{rr}$  cycle after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR. A new command is not issued for the duration of the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR after the  $T_{rr}$  cycle. The WTRC1 and WTRC0 bits must be set so as to satisfy the SDRAM refreshing cycle time stipulation ( $t_{RC}$ ). An idle cycle is inserted between the  $T_p$  cycle and  $T_{rr}$  cycle when the setting value of the WTRP1 and WTRP0 bits in CS3WCR is longer than or equal to 1 cycle.

- Notes: 1. Address pin to be connected to pin A10 of SDRAM.  
 2. The waveform for DACKn is when active low is specified.

**Figure 9.29 Auto-Refresh Timing**

## (b) Self-refreshing

Self-refresh mode is a standby mode in which the refresh timing and refresh addresses are generated within the SDRAM. Self-refreshing is activated by setting both the RMODE bit and the RFSH bit in SDCR to 1. After starting the self-refreshing, PALL command is issued in  $T_p$  cycle after the completion of the pre-charging bank. A SELF command is then issued after inserting idle cycles of which number is specified by the WTRP1 and WTRP0 bits in CS3WSR. SDRAM cannot be accessed while in the self-refresh state. Self-refresh mode is cleared by clearing the RMODE bit to 0. After self-refresh mode has been cleared, command issuance is disabled for the number of cycles specified by the WTRC1 and WTRC0 bits in CS3WCR.

Self-refresh timing is shown in figure 9.30. Settings must be made so that self-refresh clearing and data retention are performed correctly, and auto-refreshing is performed at the correct intervals. When self-refreshing is activated from the state in which auto-refreshing is set, or when exiting standby mode other than through a power-on reset, auto-refreshing is restarted if the RFSH bit is set to 1 and the RMODE bit is cleared to 0 when self-refresh mode is cleared. If the transition from clearing of self-refresh mode to the start of auto-refreshing takes time, this time should be taken into consideration when setting the initial value of RTCNT. Making the RTCNT value 1 less than the RTCOR value will enable refreshing to be started immediately.

After self-refreshing has been set, the self-refresh state continues even if the chip standby state is entered using the LSI standby function, and is maintained even after recovery from standby mode due to an interrupt. Note that the necessary signals such as CKE must be driven even in standby state by setting the HIZCNT bit in CMNCR to 1.

The self-refresh state is not cleared by a manual reset. In case of a power-on reset, the bus state controller's registers are initialized, and therefore the self-refresh state is cleared.

Notes: 1. Address pin to be connected to pin A10 of SDRAM.

2. The waveform for DACKn is when active low is specified.

**Figure 9.30 Self-Refresh Timing**

## (9) Relationship between Refresh Requests and Bus Cycles

If a refresh request occurs during bus cycle execution, the refresh cycle must wait for the bus cycle to be completed. If a refresh request occurs while the bus is released by the bus arbitration function, the refresh will not be executed until the bus mastership is acquired. This LSI has the REFOUT pin to request the bus while waiting for refresh execution. For REFOUT pin function selection, see section 22, Pin Function Controller (PFC). This LSI continues to assert REFOUT (low level) until the bus is acquired.

On receiving the asserted REFOUT signal, the external device must negate the BREQ signal and return the bus. If the external bus does not return the bus for a period longer than the specified refresh interval, refresh cannot be executed and the SDRAM contents may be lost.

If a new refresh request occurs while waiting for the previous refresh request, the previous refresh request is deleted. To refresh correctly, a bus cycle longer than the refresh interval or the bus mastership occupation must be prevented from occurring.

If a bus mastership is requested during self-refresh, the bus will not be released until the refresh is completed.

## (10) Low-Frequency Mode

When the SLOW bit in SDCR is set to 1, output of commands, addresses, and write data, and fetch of read data are performed at a timing suitable for operating SDRAM at a low frequency.

Figure 9.31 shows the access timing in low-frequency mode. In this mode, commands, addresses, and write data are output in synchronization with the falling edge of CK, which is half a cycle delayed than the normal timing. Read data is fetched at the rising edge of CK, which is half a cycle faster than the normal timing. This timing allows the hold time of commands, addresses, write data, and read data to be extended.

If SDRAM is operated at a high frequency with the SLOW bit set to 1, the setup time of commands, addresses, write data, and read data are not guaranteed. Take the operating frequency and timing design into consideration when making the SLOW bit setting.

**Figure 9.31 Low-Frequency Mode Access Timing**

## (11) Power-Down Mode

If the PDOWN bit in SDCR is set to 1, the SDRAM is placed in power-down mode by bringing the CKE signal to the low level in the non-access cycle. This power-down mode can effectively lower the power consumption in the non-access cycle. However, please note that if an access occurs in power-down mode, a cycle of overhead occurs because a cycle is needed to assert the CKE in order to cancel power-down mode.

Figure 9.32 shows the access timing in power-down mode.

**Figure 9.32 Power-Down Mode Access Timing**

## (12) Power-On Sequence

In order to use SDRAM, mode setting must first be made for SDRAM after waiting for 100  $\mu$ s or a longer period after powering on. This 100- $\mu$ s or longer period should be obtained by a power-on reset generating circuit or software.

To perform SDRAM initialization correctly, the bus state controller registers must first be set, followed by a write to the SDRAM mode register. In SDRAM mode register setting, the address signal value at that time is latched by a combination of the  $\overline{\text{CSn}}$ ,  $\overline{\text{RASU}}$ ,  $\overline{\text{RASL}}$ ,  $\overline{\text{CASU}}$ ,  $\overline{\text{CASL}}$ , and  $\text{RD}/\overline{\text{WR}}$  signals. If the value to be set is X, the bus state controller provides for value X to be written to the SDRAM mode register by performing a write to address H'FFFC4000 + X for area 2 SDRAM, and to address H'FFFC5000 + X for area 3 SDRAM. In this operation the data is ignored, but the mode write is performed as a byte-size access. To set burst read/single write, CAS latency 2 to 3, wrap type = sequential, and burst length 1 supported by the LSI, arbitrary data is written in a byte-size access to the addresses shown in table 9.18. In this time 0 is output at the external address pins of A12 or later.

**Table 9.18 Access Address in SDRAM Mode Register Write**

- Setting for Area 2

Burst read/single write (burst length 1):

| Data Bus Width | CAS Latency | Access Address | External Address Pin |
|----------------|-------------|----------------|----------------------|
| 16 bits        | 2           | H'FFFC4440     | H'0000440            |

|                                                                   | A7 to A5  | 010 (CAS latency 2), 011 (CAS latency 3)                                |
|                                                                   | A4        | 0 (lap time = sequential)                                               |
|                                                                   | A3 to A1  | 000 (burst length 1)                                                    |

Mode register setting timing is shown in figure 9.33. A PALL command (all bank pre-charge command) is firstly issued. A REF command (auto refresh command) is then issued 8 times. An MRS command (mode register write command) is finally issued. Idle cycles, of which number is specified by the WTRP1 and WTRP0 bits in CS3WCR, are inserted between the PALL and the first REF. Idle cycles, of which number is specified by the WTRC1 and WTRC0 bits in CS3WCR,

are inserted between REF and REF, and between the 8th REF and MRS. Idle cycles, of which number is one or more, are inserted between the MRS and a command to be issued next.

It is necessary to keep idle time of certain cycles for SDRAM before issuing PALL command after power-on. Refer to the manual of the SDRAM for the idle time to be needed. When the pulse width of the reset signal is longer than the idle time, mode register setting can be started immediately after the reset, but care should be taken when the pulse width of the reset signal is shorter than the idle time.

**Figure 9.33 SDRAM Mode Write Timing (Based on JEDEC)**

### (13) Low-Power SDRAM

The low-power SDRAM can be accessed using the same protocol as the normal SDRAM.

The differences between the low-power SDRAM and normal SDRAM are that partial refresh takes place that puts only a part of the SDRAM in the self-refresh state during the self-refresh function, and that power consumption is low during refresh under user conditions such as the operating temperature. The partial refresh is effective in systems in which there is data in a work area other than the specific area can be lost without severe repercussions.

The low-power SDRAM supports the extension mode register (EMRS) in addition to the mode registers as the normal SDRAM. This LSI supports issuing of the EMRS command.

The EMRS command is issued according to the conditions specified in table below. For example, if data H'0YYYYYYY is written to address H'FFFC5XX0 in longword, the commands are issued to the CS3 space in the following sequence: PALL -> REF  $\times$  8 -> MRS -> EMRS. In this case, the MRS and EMRS issue addresses are H'0000XX0 and H'YYYYYYY, respectively. If data H'1YYYYYYY is written to address H'FFFC5XX0 in longword, the commands are issued to the CS3 space in the following sequence: PALL -> MRS -> EMRS.

However, since addresses written to this LSI are output without change, set data in accord with the EMRS specifications for the given SDRAM area.

**Table 9.19 Output Addresses when EMRS Command Is Issued**

| Command to be Issued                | Access Address | Access Data | Write Access Size | MRS Command Issue Address | EMRS Command Issue Address |
|-------------------------------------|----------------|-------------|-------------------|---------------------------|----------------------------|
| CS2 MRS                             | H'FFFC4XX0     | H'*****     | 16 bits           | H'0000XX0                 | —                          |
| CS3 MRS                             | H'FFFC5XX0     | H'*****     | 16 bits           | H'0000XX0                 | —                          |
| CS2 MRS + EMRS<br>(with refresh)    | H'FFFC4XX0     | H'0YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS3 MRS + EMRS<br>(with refresh)    | H'FFFC5XX0     | H'0YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS2 MRS + EMRS<br>(without refresh) | H'FFFC4XX0     | H'1YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |
| CS3 MRS + EMRS<br>(without refresh) | H'FFFC5XX0     | H'1YYYYYYY  | 32 bits           | H'0000XX0                 | H'YYYYYYY                  |

**Figure 9.34 EMRS Command Issue Timing**

- Deep power-down mode

The low-power SDRAM supports deep power-down mode as a low-power consumption mode. In the partial self-refresh function, self-refresh is performed on a specific area. In deep power-down mode, self-refresh will not be performed on any memory area. This mode is effective in systems where all of the system memory areas are used as work areas.

If the RMODE bit in the SDCR is set to 1 while the DEEP and RFSH bits in the SDCR are set to 1, the low-power SDRAM enters deep power-down mode. If the RMODE bit is cleared to 0, the CKE signal is pulled high to cancel deep power-down mode. Before executing an access after returning from deep power-down mode, the power-up sequence must be re-executed.

**Figure 9.35 Deep Power-Down Mode Transition Timing**

### 9.5.7 Burst ROM (Clock Asynchronous) Interface

The burst ROM (clock asynchronous) interface is used to access a memory with a high-speed read function using a method of address switching called burst mode or page mode. In a burst ROM (clock asynchronous) interface, basically the same access as the normal space is performed, but the 2nd and subsequent access cycles are performed only by changing the address, without negating the  $\overline{RD}$  signal at the end of the 1st cycle. In the 2nd and subsequent access cycles, addresses are changed at the falling edge of the CK.

For the 1st access cycle, the number of wait cycles specified by the W3 to W0 bits in CSnWCR is inserted. For the 2nd and subsequent access cycles, the number of wait cycles specified by the W1 to W0 bits in CSnWCR is inserted.

In the access to the burst ROM (clock asynchronous), the  $\overline{BS}$  signal is asserted only to the first access cycle. An external wait input is valid only to the first access cycle.

In the single access or write access that does not perform the burst operation in the burst ROM (clock asynchronous) interface, access timing is same as a normal space.

Table 9.20 lists a relationship between bus width, access size, and the number of bursts. Figure 9.36 shows a timing chart.

**Table 9.20 Relationship between Bus Width, Access Size, and Number of Bursts**

| Bus Width | Access Size            | CSnWCR. BST[1:0] Bits | Number of Bursts | Access Count |
|-----------|------------------------|-----------------------|------------------|--------------|
| 8 bits    | 8 bits                 | Not affected          | 1                | 1            |
|           | 16 bits                | Not affected          | 2                | 1            |
|           | 32 bits                | Not affected          | 4                | 1            |
|           | 16 bytes* <sup>2</sup> | x0                    | 16               | 1            |
|           |                        | 10                    | 4                | 4            |
| 16 bits   | 8 bits                 | Not affected          | 1                | 1            |
|           | 16 bits                | Not affected          | 1                | 1            |
|           | 32 bits                | Not affected          | 2                | 1            |
|           | 16 bytes* <sup>2</sup> | 00                    | 8                | 1            |
|           |                        | 01                    | 2                | 4            |
|           |                        | 10* <sup>1</sup>      | 4                | 2            |
|           |                        |                       | 2, 4, 2          | 3            |
| 32 bits   | 8 bits                 | Not affected          | 1                | 1            |
|           | 16 bits                | Not affected          | 1                | 1            |
|           | 32 bits                | Not affected          | 1                | 1            |
|           | 16 bytes* <sup>2</sup> | Not affected          | 4                | 1            |

- Notes: 1. When the bus width is 16 bits, the access size is 16 bits, and the BST[1:0] bits in CSnWCR are 10, the number of bursts and access count depend on the access start address. At address H'xxx0 or H'xxx8, 4-4 burst access is performed. At address H'xxx4 or H'xxxC, 2-4-2 burst access is performed.
2. Only the DMAC is capable of transfer with 16 bytes as the unit of access. The maximum unit of access for the DTC, E-DMAC, and CPU is 32 bits.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.36 Burst ROM Access Timing (Clock Asynchronous)**  
 (Bus Width = 32 Bits, 16-Byte Transfer (Number of Burst 4), Wait Cycles Inserted in First Access = 2, Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)

### 9.5.8 SRAM Interface with Byte Selection

The SRAM interface with byte selection is for access to an SRAM which has a byte-selection pin ( $\overline{WR_{xx}}$ ). This interface has 16-bit data pins and accesses SRAMs having upper and lower byte selection pins, such as UB and LB.

When the BAS bit in CSnWCR is cleared to 0 (initial value), the write access timing of the SRAM interface with byte selection is the same as that for the normal space interface. While in read access of a byte-selection SRAM interface, the byte-selection signal is output from the  $\overline{WR_{xx}}$  pin, which is different from that for the normal space interface. The basic access timing is shown in figure 9.37. In write access, data is written to the memory according to the timing of the byte-selection pin ( $\overline{WR_{xx}}$ ). For details, please refer to the Data Sheet for the corresponding memory.

If the BAS bit in CSnWCR is set to 1, the  $\overline{WR_{xx}}$  pin and RD/ $\overline{WR}$  pin timings change. Figure 9.38 shows the basic access timing. In write access, data is written to the memory according to the timing of the write enable pin (RD/ $\overline{WR}$ ). The data hold timing from RD/ $\overline{WR}$  negation to data write must be acquired by setting the HW1 and HW0 bits in CSnWCR. Figure 9.39 shows the access timing when a software wait is specified.

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.37 Basic Access Timing for SRAM with Byte Selection (BAS = 0)**

Note: \* The waveform for DACKn is when active low is specified.

**Figure 9.41 Example of Connection with 16-Bit Data-Width SRAM with Byte Selection**

### 9.5.9 Burst ROM (Clock Synchronous) Interface

The burst ROM (clock synchronous) interface is supported to access a ROM with a synchronous burst function at high speed. The burst ROM interface accesses the burst ROM in the same way as a normal space. This interface is valid only for area 0.

In the first access cycle, wait cycles are inserted. In this case, the number of wait cycles to be inserted is specified by the W3 to W0 bits in CS0WCR. In the second and subsequent cycles, the number of wait cycles to be inserted is specified by the BW1 and BW0 bits in CS0WCR.

While the burst ROM (clock synchronous) is accessed, the  $\overline{BS}$  signal is asserted only for the first access cycle and an external wait input is also valid for the first access cycle.

If the bus width is 16 bits, the burst length must be specified as 8. The burst ROM interface does not support the 8-bit bus width for the burst ROM.

The burst ROM interface performs burst operations for all read access. For example, in a longword access over a 16-bit bus, valid 16-bit data is read two times and invalid 16-bit data is read six times. These invalid data read cycles increase the memory access time and degrade the program execution speed and DMA transfer speed. To prevent this problem, using 16-byte read by the DMA is recommended. The burst ROM interface performs write access in the same way as normal space access.

**Figure 9.42 Burst ROM Access Timing (Clock Synchronous)**  
**(Burst Length = 8, Wait Cycles Inserted in First Access = 2,**  
**Wait Cycles Inserted in Second and Subsequent Access Cycles = 1)**

### 9.5.10 Wait between Access Cycles

As the operating frequency of LSIs becomes higher, the off-operation of the data buffer often collides with the next data access when the read operation from devices with slow access speed is completed. As a result of these collisions, the reliability of the device is low and malfunctions may occur. A function that avoids data collisions by inserting idle (wait) cycles between continuous access cycles has been newly added.

The number of wait cycles between access cycles can be set by the WM bit in CSnWCR, bits IWW2 to IWW0, IWRWD2 to IWRWD0, IWRWS2 to IWRWS0, IWRRD2 to IWRRD0, and IWRRS2 to IWRRS 0 in CSnBCR, and bits DMAIW2 to DMAIW0 and DMAIWA in CMNCR. The conditions for setting the idle cycles between access cycles are shown below.

1. Continuous access cycles are write-read or write-write
2. Continuous access cycles are read-write for different spaces
3. Continuous access cycles are read-write for the same space
4. Continuous access cycles are read-read for different spaces
5. Continuous access cycles are read-read for the same space
6. Data output from an external device caused by DMA single address transfer is followed by data output from another device that includes this LSI (DMAIWA = 0)
7. Data output from an external device caused by DMA single address transfer is followed by any type of access (DMAIWA = 1)

For the specification of the number of idle cycles between access cycles described above, refer to the description of each register.

Besides the idle cycles between access cycles specified by the registers, idle cycles must be inserted to interface with the internal bus or to obtain the minimum pulse width for a multiplexed pin ( $\overline{\text{WRxx}}$ ). The following gives detailed information about the idle cycles and describes how to estimate the number of idle cycles.

The number of idle cycles on the external bus from  $\overline{\text{CSn}}$  negation to  $\overline{\text{CSn}}$  or  $\overline{\text{CSm}}$  assertion is described below.

There are eight conditions that determine the number of idle cycles on the external bus as shown in table 9.21. The effects of these conditions are shown in figure 9.43.

**Table 9.21 Conditions for Determining Number of Idle Cycles**

| No. | Condition                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Range   | Note                                                                                                                                                                                                                                              |
|-----|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (1) | DMAIW[2:0] in CMNCR          | These bits specify the number of idle cycles for DMA single address transfer. This condition is effective only for single address transfer and generates idle cycles after the access is completed.                                                                                                                                                                                                                                                                                                                                     | 0 to 12 | When 0 is specified for the number of idle cycles, the DACK signal may be asserted continuously. This causes a discrepancy between the number of cycles detected by the device with DACK and the DMAC transfer count, resulting in a malfunction. |
| (2) | IW***[2:0] in CSnBCR         | These bits specify the number of idle cycles for access other than single address transfer. The number of idle cycles can be specified independently for each combination of the previous and next cycles. For example, in the case where reading CS1 space followed by reading other CS space, the bits IWRRD[2:0] in CS1BCR should be set to B'100 to specify six or more idle cycles. This condition is effective only for access cycles other than single address transfer and generates idle cycles after the access is completed. | 0 to 12 | Do not set 0 for the number of idle cycles between memory types which are not allowed to be accessed successively.                                                                                                                                |
| (3) | SDRAM-related bits in CSnWCR | These bits specify precharge completion and startup wait cycles and idle cycles between commands for SDRAM access. This condition is effective only for SDRAM access and generates idle cycles after the access is completed                                                                                                                                                                                                                                                                                                            | 0 to 3  | Specify these bits in accordance with the specification of the target SDRAM.                                                                                                                                                                      |
| (4) | WM in CSnWCR                 | This bit enables or disables external WAIT pin input for the memory types other than SDRAM. When this bit is cleared to 0 (external WAIT enabled), one idle cycle is inserted to check the external WAIT pin input after the access is completed. When this bit is set to 1 (disabled), no idle cycle is generated.                                                                                                                                                                                                                     | 0 or 1  |                                                                                                                                                                                                                                                   |

| No. | Condition                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                | Range       | Note                                                                                                                                                                                                                                                                                                                                 |
|-----|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (5) | Read data transfer cycle                   | One idle cycle is inserted after a read access is completed. This idle cycle is not generated for the first or middle cycles in divided access cycles. This is neither generated when the HW[1:0] bits in CSnWCR are not B'00.                                                                                                                                                                                                                             | 0 or 1*     | One idle cycle is always generated after a read cycle with SDRAM interface.                                                                                                                                                                                                                                                          |
| (6) | Internal bus idle cycles, etc.             | External bus access requests from the CPU or DMAC and their results are passed through the internal bus. The external bus enters idle state during internal bus idle cycles or while a bus other than the external bus is being accessed. This condition is not effective for divided access cycles, which are generated by the BSC when the access size is larger than the external data bus width.                                                       | 0 or larger | The number of internal bus idle cycles may not become 0 depending on the $f_{\phi:B\phi}$ clock ratio. Tables 9.22 and 9.23 show the relationship between the clock ratio and the minimum number of internal bus idle cycles.                                                                                                        |
| (7) | Write data wait cycles                     | During write access, a write cycle is executed on the external bus only after the write data becomes ready. This write data wait period generates idle cycles before the write cycle. Note that when the previous cycle is a write cycle and the internal bus idle cycles are shorter than the previous write cycle, write data can be prepared in parallel with the previous write cycle and therefore, no idle cycle is generated (write buffer effect). | 0 or 1      | For write → write or write → read access cycles, successive access cycles without idle cycles are frequently available due to the write buffer effect described in the left column. If successive access cycles without idle cycles are not allowed, specify the minimum number of idle cycles between access cycles through CSnBCR. |
| (8) | Idle cycles between different memory types | To ensure the minimum pulse width on the signal-multiplexed pins, idle cycles may be inserted before access after memory types are switched. For some memory types, idle cycles are inserted even when memory types are not switched.                                                                                                                                                                                                                      | 0 to 2.5    | The number of idle cycles depends on the target memory types. See table 9.24.                                                                                                                                                                                                                                                        |

Note: \* This is the case for consecutive read operations when the data read are stored in separate registers.

In the above conditions, a total of four conditions, that is, condition (1) or (2) (either one is effective), condition (3) or (4) (either one is effective), a set of conditions (5) to (7) (these are generated successively, and therefore the sum of them should be taken as one set of idle cycles), and condition (8) are generated at the same time. The maximum number of idle cycles among these four conditions becomes the number of idle cycles on the external bus. To ensure the minimum idle cycles, be sure to make register settings for condition (1) or (2).

Note: A total of four conditions (condition [1] or [2], condition [3] or [4], a set of conditions [5] to [7], and condition [8]) generate idle cycle at the same time. Accordingly, the maximum number of cycles among these four conditions become the number of idle cycles.

**Figure 9.43 Idle Cycle Conditions**

**Table 9.22 Minimum Number of Idle Cycles on Internal Bus (CPU Operation)**

| CPU Operation | Clock Ratio ( $I\phi:B\phi$ ) |     |     |     |
|---------------|-------------------------------|-----|-----|-----|
|               | 8:1                           | 4:1 | 2:1 | 1:1 |
| Write → write | 0                             | 0   | 0   | 0   |
| Write → read  | 0                             | 0   | 0   | 0   |
| Read → write  | 1                             | 1   | 2   | 3   |
| Read → read   | 0                             | 0   | 0   | 0   |

Conditions:

- The bits for setting the idle cycles between access cycles in CS1BCR and CS2BCR are all set to 0.
- In CS1WCR and CS2WCR, the WM bit is set to 1 (external  $\overline{WAIT}$  pin disabled) and the HW[1:0] bits are set to 00 ( $\overline{CS}$  negation is not extended).
- For both the CS1 and CS2 spaces, normal SRAM devices are connected, the bit width is 32 bits, and access size is also 32 bits.

**Table 9.23 Minimum Number of Idle Cycles on Internal Bus (DMAC Operation)**

| DMAC Operation    | Transfer Mode |                           |                          |                         |                          |                         |
|-------------------|---------------|---------------------------|--------------------------|-------------------------|--------------------------|-------------------------|
|                   | Dual Address  |                           |                          |                         | Single Address*2         |                         |
| Activation source | Auto request  | Peripheral module request | External request (level) | External request (edge) | External request (level) | External request (edge) |
| Write → write     | 1             | 1                         | 3                        | 3                       | 6                        | 1                       |
| Write → read      | 0             | 0                         | 2 or 0*1                 | 1 or 0*1                | 0                        | 0                       |
| Read → write      | 0             | 0                         | 0                        | 0                       | 0                        | 0                       |
| Read → read       | 2             | 2                         | 5                        | 4                       | 5                        | 2                       |

Operating conditions:

1. The write → write cycle means transfer from an on-chip memory to an external memory. The read → read cycle means transfer from an external memory to an on-chip memory. The write → read cycle and read → write cycle mean transfer between external memories. Each of the operations is performed in burst mode.
2. The external data bus width is 16 bits and the DMA transfer size is 16 bits.
3.  $Ick : Bck = 1 : 1/4$

- Notes: 1. For the write → read cycles in transfer with an external request (level), 0 means different channels are activated successively and 2 means the same channel is activated successively.  
For the write → read cycles in transfer with an external request (edge), 0 means different channels are activated successively and 1 means the same channel is activated successively.
2. The write → read and read → write columns in single address transfer indicate the case when different channels are activated successively. The "write" means transfer from a device with DACK to external memory and the "read" means transfer from external memory to a device with DACK.

**Table 9.24 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types**

| Previous Cycle                   | Next Cycle |                             |             |                        |                        |       |                                  |                            |
|----------------------------------|------------|-----------------------------|-------------|------------------------|------------------------|-------|----------------------------------|----------------------------|

Figure 9.43 shows sample estimation of idle cycles between access cycles. In the actual operation, the idle cycles may become shorter than the estimated value due to the write buffer effect or may become longer due to internal bus idle cycles caused by stalling in the pipeline due to CPU instruction execution or CPU register conflicts. Please consider these errors when estimating the idle cycles.

## Sample Estimation of Idle Cycles between Access Cycles

This example estimates the idle cycles for data transfer from the CS1 space to CS2 space by CPU access. Transfer is repeated in the following order: CS1 read → CS1 read → CS2 write → CS2 write → CS1 read → ...

- Conditions

The bits for setting the idle cycles between access cycles in CS1BCR and CS2BCR are all set to 0.

In CS1WCR and CS2WCR, the WM bit is set to 1 (external  $\overline{\text{WAIT}}$  pin disabled) and the HW[1:0] bits are set to 00 (CS negation is not extended).

$\phi:B\phi$  is set to 4:1, and no other processing is done during transfer.

For both the CS1 and CS2 spaces, normal SRAM devices are connected, the bus width is 32 bits, and access size is also 32 bits.

The idle cycles generated under each condition are estimated for each pair of access cycles. In the following table, R indicates a read cycle and W indicates a write cycle.

| Condition             | R → R | R → W | W → W | W → R | Note                                                                                                                                                                                                                                                     |
|-----------------------|-------|-------|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [1] or [2]            | 0     | 0     | 0     | 0     | CSnBCR is set to 0.                                                                                                                                                                                                                                      |
| [3] or [4]            | 0     | 0     | 0     | 0     | The WM bit is set to 1.                                                                                                                                                                                                                                  |
| [5]                   | 1     | 1     | 0     | 0     | Generated after a read cycle.                                                                                                                                                                                                                            |
| [6]                   | 0     | 1     | 0     | 0     | See the $\phi:B\phi = 4:1$ column in table 9.22.                                                                                                                                                                                                         |
| [7]                   | 0     | 1     | 0     | 0     | No idle cycle is generated for the second time due to the write buffer effect.                                                                                                                                                                           |
| [5] + [6] + [7]       | 1     | 3     | 0     | 0     |                                                                                                                                                                                                                                                          |
| [8]                   | 0     | 0     | 0     | 0     | Value for SRAM → SRAM access                                                                                                                                                                                                                             |
| Estimated idle cycles | 1     | 3     | 0     | 0     | Maximum value among conditions [1] or [2], [3] or [4], [5] + [6] + [7], and [8]                                                                                                                                                                          |
| Actual idle cycles    | 1     | 3     | 0     | 1     | The estimated value does not match the actual value in the W → R cycles because the internal idle cycles due to condition [6] is estimated as 0 but actually an internal idle cycle is generated due to execution of a loop condition check instruction. |

**Figure 9.44 Comparison between Estimated Idle Cycles and Actual Value**

### 9.5.11 Bus Arbitration

In bus arbitration by this LSI, it normally holds bus mastership but can release this after receiving a bus request from another device.

Bus arbitration by this LSI also supports four on-chip bus masters: the CPU, DMAC, DTC, and EDMAC. The priority order of these bus masters is as follows.

Bus mastership request from an external device ( $\overline{\text{BREQ}}$ ) > EDMAC > DTC > DMAC > CPU.

Bus mastership is transferred at the boundary of bus cycles. Namely, bus mastership is released immediately after receiving a bus request when a bus cycle is not being performed. The release of bus mastership is delayed until the bus cycle is complete when a bus cycle is in progress. Even when from outside the LSI it looks like a bus cycle is not being performed, a bus cycle may be performing internally, started by inserting wait cycles between access cycles. Therefore, it cannot be immediately determined whether or not bus mastership has been released by looking at the  $\overline{\text{CSn}}$  signal or other bus control signals. The states that do not allow bus mastership release are shown below.

1. Between the read and write cycles of a TAS instruction, or 64-bit transfer cycle of an FMOV instruction
2. Multiple bus cycles generated when the data bus width is smaller than the access size (for example, between bus cycles when longword access is made to a memory with a data bus width of 8 bits)
3. 16-byte transfer by the DMAC
4. Setting the BLOCK bit in CMNCR to 1

Moreover, by using DPRTY bit in CMNCR, whether the bus mastership request is received or not can be selected during DMAC burst transfer.

The LSI has the bus mastership until a bus request is received from another device. Upon acknowledging the assertion (low level) of the external bus request signal  $\overline{\text{BREQ}}$ , the LSI releases the bus at the completion of the current bus cycle and asserts the  $\overline{\text{BACK}}$  signal. After the LSI acknowledges the negation (high level) of the  $\overline{\text{BREQ}}$  signal that indicates the external device has released the bus, it negates the  $\overline{\text{BACK}}$  signal and resumes the bus usage.

With the SDRAM interface, all bank pre-charge commands (PALLs) are issued when active banks exist and the bus is released after completion of a PALL command.

The bus sequence is as follows. The address bus and data bus are placed in a high-impedance state synchronized with the rising edge of CK. The bus mastership enable signal is asserted 0.5 cycles

after the above timing, synchronized with the falling edge of CK. The bus control signals ( $\overline{BS}$ ,  $\overline{CSn}$ ,  $\overline{RASL}$ ,  $\overline{CASL}$ ,  $\overline{CKE}$ ,  $\overline{DQMxx}$ ,  $\overline{WRxx}$ ,  $\overline{RD}$ , and  $\overline{RD/WR}$ ) are placed in the high-impedance state at subsequent rising edges of CK. Bus request signals are sampled at the falling edge of CKIO. Note that  $\overline{CKE}$ ,  $\overline{RASL}$ , and  $\overline{CASL}$  can continue to be driven at the previous value even in the bus-released state by setting the HIZCNT bit in CMNCR.

The sequence for reclaiming the bus mastership from an external device is described below. 1.5 cycles after the negation of  $\overline{BREQ}$  is detected at the falling edge of CK, the bus control signals are driven high. The bus acknowledge signal is negated at the next falling edge of the clock. The fastest timing at which actual bus cycles can be resumed after bus control signal assertion is at the rising edge of the CK where address and data signals are driven. Figure 9.44 shows the bus arbitration timing.

When it is necessary to refresh SDRAM while releasing the bus mastership, the bus mastership should be returned using the  $\overline{REFOUT}$  signal. For details on the selection of  $\overline{REFOUT}$ , see section 22, Pin Function Controller (PFC). The  $\overline{REFOUT}$  signal is kept asserting at low level until the bus mastership is acquired. The  $\overline{BREQ}$  signal is negated by asserting the  $\overline{REFOUT}$  signal and the bus mastership is returned from the external device. If the bus mastership is not returned for a refreshing period or longer, the contents of SDRAM cannot be guaranteed because a refreshing cannot be executed.

While releasing the bus mastership, the SLEEP instruction (to enter sleep mode or standby mode), as well as a manual reset, cannot be executed until the LSI obtains the bus mastership.

The  $\overline{BREQ}$  input signal is ignored in standby mode and the  $\overline{BACK}$  output signal is placed in the high impedance state. If the bus mastership request is required in this state, the bus mastership must be released by pulling down the  $\overline{BACK}$  pin to enter standby mode.

The bus mastership release ( $\overline{BREQ}$  signal for high level negation) after the bus mastership request ( $\overline{BREQ}$  signal for low level assertion) must be performed after the bus usage permission ( $\overline{BACK}$  signal for low level assertion). If the  $\overline{BREQ}$  signal is negated before the  $\overline{BACK}$  signal is asserted, only one cycle of the  $\overline{BACK}$  signal is asserted depending on the timing of the  $\overline{BREQ}$  signal to be negated and this may cause a bus contention between the external device and the LSI.

**Figure 9.45 Bus Arbitration Timing**

### 9.5.12 Others

#### (1) Reset

The bus state controller (BSC) can be initialized completely only at power-on reset. At power-on reset, all signals are negated and data output buffers are turned off regardless of the bus cycle state after the internal reset is synchronized with the internal clock. All control registers are initialized. In standby, sleep, and manual reset, control registers of the bus state controller are not initialized. At manual reset, only the current bus cycle being executed is completed. Since the RTCNT continues counting up during manual reset signal assertion, a refresh request occurs to initiate the refresh cycle.

#### (2) Access from the Side of the LSI Internal Bus Master

Since the bus state controller (BSC) incorporates a four-stage write buffer, the BSC can execute an access via the internal bus before the previous external bus cycle is completed in a write cycle. If the on-chip module is read or written after the external low-speed memory is written, the on-chip module can be accessed before the completion of the external low-speed memory write cycle.

In read cycles, the CPU is placed in the wait state until read operation has been completed. To continue the process after the data write to the device has been completed, perform a dummy read to the same address to check for completion of the write before the next process to be executed.

The write buffer of the BSC functions in the same way for an access by a bus master other than the CPU such as the DMAC. Accordingly, to perform dual address DMA transfers, the next read cycle is initiated before the previous write cycle is completed. Note, however, that if both the DMA source and destination addresses exist in external memory space, the next write cycle will not be initiated until the previous write cycle is completed.

Changing the registers in the BSC while the write buffer is operating may disrupt correct write access. Therefore, do not change the registers in the BSC immediately after a write access. If this change becomes necessary, do it after executing a dummy read of the write data.

### (3) On-Chip Peripheral Module Access

To access an on-chip module register, two or more peripheral module clock (P $\phi$ ) cycles are required. Care must be taken in system design.

When the CPU writes data to the internal peripheral registers, the CPU performs the succeeding instructions without waiting for the completion of writing to registers.

For example, a case is described here in which the system is transferring to software standby mode for power savings. To make this transition, the SLEEP instruction must be performed after setting the STBY bit in the STBCR register to 1. However a dummy read of the STBCR register is required before executing the SLEEP instruction. If a dummy read is omitted, the CPU executes the SLEEP instruction before the STBY bit is set to 1, thus the system enters sleep mode not software standby mode. A dummy read of the STBCR register is indispensable to complete writing to the STBY bit.

To reflect the change by internal peripheral registers while performing the succeeding instructions, execute a dummy read of registers to which write instruction is given and then perform the succeeding instructions.

Table 9.25 shows the number of cycles required for access to the on-chip peripheral I/O registers by the CPU.

**Table 9.25 Number of Cycles for Access to On-Chip Peripheral Module Registers**

|       | Number of Access Cycles                                                               | Remarks                                |
|-------|---------------------------------------------------------------------------------------|----------------------------------------|
| Write | $(2 + n) \times l\phi + (1 + m) \times B\phi + 2 \times P\phi$                        | Except for the FLD, E-DMAC, and EtherC |
|       | $(2 + n) \times l\phi + (1 + m) \times B\phi + 3 \times P\phi$                        | FLD access                             |
|       | $(2 + n) \times l\phi + 3 \times B\phi$                                               | E-DMAC access                          |
|       | $(2 + n) \times l\phi + 9 \times B\phi$                                               | EtherC access                          |
| Read  | $(2 + n) \times l\phi + (1 + m) \times B\phi + 2 \times P\phi + (2 + l) \times l\phi$ | Except for the FLD, E-DMAC, and EtherC |
|       | $(2 + n) \times l\phi + (1 + m) \times B\phi + 3 \times P\phi + (2 + l) \times l\phi$ | FLD access                             |
|       | $(2 + n) \times l\phi + 4 \times B\phi + (2 + l) \times l\phi$                        | E-DMAC access                          |
|       | $(2 + n) \times l\phi + 12 \times B\phi + (2 + l) \times l\phi$                       | EtherC access                          |

Notes: The above indicates the number of access cycles of which executed when the instructions are by on-chip ROM or by on-chip RAM.

When  $l\phi:B\phi = 1:1$ ,  $n = 0$  and  $l = 0$ .

When  $l\phi:B\phi = 2:1$ ,  $n = 1$  to 0 and  $l = 0$ .

When  $l\phi:B\phi = 4:1$ ,  $n = 3$  to 0 and  $l = 0, 1$ .

When  $I\phi:B\phi = 8:1$ ,  $n = 7$  to  $0$  and  $l = 1$ .

When  $B\phi:P\phi = 1:1$ ,  $m = 0$ .

When  $B\phi:P\phi = 2:1$ ,  $m = 1, 0$ .

$n$  and  $m$  depend on the internal execution state.

Synchronous logic and a layered bus structure have been adopted for this LSI. Data on each bus are input and output in synchronization with rising edges of the corresponding clock signal. The C bus, the I bus, and the peripheral bus are synchronized with the  $I\phi$ ,  $B\phi$ , and  $P\phi$  clock, respectively.

Figure 9.45 shows an example of the timing of write access to the peripheral bus when  $I\phi:B\phi:P\phi = 4:1:1$ . Data are output to the C bus, which is connected to the CPU, in synchronization with  $I\phi$ . When  $I\phi:B\phi = 4:1$ , there are 4 cycles of this clock to one cycle of  $B\phi$ , so four transfers to the I bus can proceed in one cycle of  $B\phi$ . Thus, a period of up to  $5 \times I\phi$  may be required before a rising edge of  $B\phi$ , which is the time of transfer from the C bus to the I bus (a case where this takes 3 cycles of  $I\phi$  is indicated in figure 9.45). When  $I\phi:B\phi = 4:1$ , transfer of data from the C bus to the I bus takes  $(2 + n) \times I\phi$  ( $n = 0$  to  $3$ ). The relation between the timing of data transfer to the C bus and the rising edge of  $B\phi$  depends on the state of program execution. When  $B\phi:P\phi = 1:1$ , transfer of data from the I bus to the peripheral bus takes  $1B\phi + 2P\phi$ . In the case shown in the figure, where  $n = 1$  and  $m = 0$ , the time required for access is  $3 \times I\phi + 2 \times B\phi + 2 \times P\phi$ .

**Figure 9.46 Timing of Write Access to On-Chip Peripheral I/O Registers**  
**When  $I\phi:B\phi:P\phi = 4:1:1$**

Figure 9.46 shows an example of timing of read access to the peripheral bus when  $I\phi:B\phi:P\phi = 4:2:1$ . Transfer from the C bus to the peripheral bus is performed in the same way as for write access. In the case of reading, however, values output onto the peripheral bus must be transferred to the CPU. Although transfers from the peripheral bus to the I bus and from the I bus to the C bus are performed in synchronization with the rising edge of the respective bus clocks, a period of  $(2 + l) \times I\phi$  is actually required because  $I\phi \geq B\phi \geq P\phi$ . In the case shown in the figure 9.46, where  $n = 1$ ,  $m = 1$ , and  $l = 1$ , the time required for access is  $3 \times I\phi + 2 \times B\phi + 2 \times P\phi + 3 \times I\phi$ .

**Figure 9.47 Timing of Read Access to On-Chip Peripheral I/O Registers  
When  $I\phi:B\phi:P\phi = 4:2:1$**

Note that the peripheral bus cycle for the FLD is different from that for other modules. The cycle for the FLD is  $3 \times P\phi$ .

#### (4) Access to On-Chip Memory and External Device

Table 9.26 shows the number of cycles required for access to the on-chip memory and external device.

**Table 9.26 Number of Cycles for Access to On-Chip Memory and External Device**

| Object to be accessed              |                         | 128-bit on-chip | On-chip RAM (lφ) |              | External device (Bφ)*5                                                                               |                                                                               |                                                                      |
|------------------------------------|-------------------------|-----------------|------------------|--------------|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------------------------|

|                                    | Data write*1 (word)     | —               | 1Bφ to 3Bφ*4     |              | 5Bφ                                                                                                  | 3Bφ                                                                           | 3Bφ                                                                  |
|                                    | Data read (byte)        | —               |                  |              | 3Bφ                                                                                                  |                                                                               |                                                                      |

- Notes:
1. Using the write buffer, the bus master can execute the succeeding processing before the previous write cycle is completed. For details, see section 9.5.12 (2), Access from the Side of the LSI Internal Bus Master.
  2. When  $I\phi:B\phi = 1:1/8$ , the value is  $3B\phi$ . When  $I\phi:B\phi$  is not  $1:1/8$ , the value is  $4I\phi + 3B\phi$ .
  3. When  $I\phi:B\phi = 8:1$ , the value is  $1B\phi$ . When  $I\phi:B\phi = 4:1$ , the value is  $2B\phi$ . When  $I\phi:B\phi = 2:1$ , the value is  $2B\phi$  to  $3B\phi$ . When  $I\phi:B\phi = 1:1$ , the value is  $3B\phi$  to  $4B\phi$ .
  4. When  $I\phi:B\phi = 8:1$ , the value is  $1B\phi$ . When  $I\phi:B\phi = 4:1$ , the value is  $1B\phi$  to  $2B\phi$ . When  $I\phi:B\phi = 2:1$ , the value is  $2B\phi$ . When  $I\phi:B\phi = 1:1$ , the value is  $2B\phi$  to  $3B\phi$ .
  5. The above indicates the number of access cycles of which executed when the instructions are by on-chip ROM or by on-chip RAM.

When  $I\phi:B\phi = 1:1$ ,  $n = 0$  and  $I = 0$ .

When  $I\phi:B\phi = 2:1$ ,  $n = 1$  to  $0$  and  $I = 0$ .

When  $I\phi:B\phi = 4:1$ ,  $n = 3$  to  $0$  and  $I = 0, 1$ .

When  $I\phi:B\phi = 8:1$ ,  $n = 7$  to  $0$  and  $I = 1$ .

$m$  = wait cycle

$o$  = idle cycle + wait cycle

$n$  and  $I$  depend on the internal execution state.

Figure 9.48 shows an example of timing of write access to the longword data and word data which are twice as much as 16- and 8-bit external bus widths, respectively, in the external memory when  $I\phi:B\phi = 2:1$ .

**Figure 9.48 Timing of Write Access to Data Beyond External Bus Width When  $I\phi:B\phi = 2:1$**

Figure 9.49 shows an example of timing of read access to the data within the external bus width from the external memory when  $I\phi:B\phi = 4:1$ .

**Figure 9.49 Timing of Read Access to Data within External Bus Width When  $I\phi:B\phi = 4:1$**

## 9.6 Interrupt Source

The BSC has the compare match interrupt (CMI) as an interrupt source.

Table 9.26 gives details on this interrupt source. The compare match interrupt enable bit (CMIE) in the refresh timer control/status register (RTCSR) can be used to enable or disable the interrupt source.

The compare match interrupt (CMI) is generated when the compare match flag (CMF) and compare match interrupt enable bit (CMIE) in RTCSR are set to 1.

Clearing the interrupt flag bit to 0 cancels the interrupt request.

**Table 9.26 Interrupt Source**

| Abbreviation | Interrupt Source        | Interrupt Enable Bit | Interrupt Flag |
|--------------|-------------------------|----------------------|----------------|
| CMI          | Compare match interrupt | CMIE                 | CMIF           |

## 9.7 Usage Note

### 9.7.1 Note on Connection of External LSI Circuits such as SDRAMs and ASICs

Each of the following pairs of pin functions among the pins for the output of SDRAM control signals is multiplexed on respective single pins:  $\overline{\text{RD}}/\overline{\text{WR}}$  and A23,  $\overline{\text{RASL}}$  and A18, and  $\overline{\text{CASL}}$  and A19. When an external chip (SDRAM, ASIC, etc.) is to be connected to the bus of this LSI, follow the procedure described below.

- Use the 23 bits from A0 to A22 as the address for the external chip such as ASICs.

## Section 10 Direct Memory Access Controller (DMAC)

The DMAC can be used in place of the CPU to perform high-speed transfers between external devices that have DACK (transfer request acknowledge signal), external memory, on-chip memory, memory-mapped external devices, and on-chip peripheral modules.

### 10.1 Features

- Number of channels selectable: Eight channels (channels 0 to 7) max.  
CH0 to CH3 channels can only receive external requests.
- 4-Gbyte physical address space
- Transfer data length is selectable: Byte, word (two bytes), longword (four bytes), and 16 bytes (longword  $\times$  4)
- Maximum transfer count: 16,777,216 transfers (24 bits)
- Address mode: Dual address mode and single address mode are supported.
- Transfer requests
  - External request
  - On-chip peripheral module request
  - Auto request

The following modules can issue on-chip peripheral module requests.

- Two SCIF sources, two IIC3 sources, one A/D converter source, five MTU2 sources, two CMT sources, four USB sources, two RSPI sources, and one RCAN-ET source
- Selectable bus modes
  - Cycle steal mode (normal mode and intermittent mode)
  - Burst mode
- Selectable channel priority levels: The channel priority levels are selectable between fixed mode and round-robin mode.
- Interrupt request: An interrupt request can be sent to the CPU on completion of half- or full-data transfer. Through the HE and HIE bits in CHCR, an interrupt is specified to be issued to the CPU when half of the initially specified DMA transfer is completed.
- External request detection: There are following four types of DREQ input detection.
  - Low level detection
  - High level detection
  - Rising edge detection
  - Falling edge detection

- Transfer request acknowledge and transfer end signals: Active levels for DACK and TEND can be set independently.
- Support of reload functions in DMA transfer information registers: DMA transfer using the same information as the current transfer can be repeated automatically without specifying the information again. Modifying the reload registers during DMA transfer enables next DMA transfer to be done using different transfer information. The reload function can be enabled or disabled independently in each channel.

Figure 10.1 shows the block diagram of the DMAC.

**Figure 10.1 Block Diagram of DMAC**

## 10.2 Input/Output Pins

The external pins for DMAC are described below. Table 10.1 lists the configuration of the pins that are connected to external bus. DMAC has pins for four channels (CH0 to CH3) as the external bus use.

**Table 10.1 Pin Configuration**

| Channel | Name                             | Abbreviation | I/O | Function                                                                     |
|---------|----------------------------------|--------------|-----|------------------------------------------------------------------------------|
| 0       | DMA transfer request             | DREQ0        | I   | DMA transfer request input from an external device to channel 0              |
|         | DMA transfer request acknowledge | DACK0        | O   | DMA transfer request acknowledge output from channel 0 to an external device |
| 1       | DMA transfer request             | DREQ1        | I   | DMA transfer request input from an external device to channel 1              |
|         | DMA transfer request acknowledge | DACK1        | O   | DMA transfer request acknowledge output from channel 1 to an external device |
| 2       | DMA transfer request             | DREQ2        | I   | DMA transfer request input from an external device to channel 2              |
|         | DMA transfer request acknowledge | DACK2        | O   | DMA transfer request acknowledge output from channel 2 to an external device |
| 3       | DMA transfer request             | DREQ3        | I   | DMA transfer request input from an external device to channel 3              |
|         | DMA transfer request acknowledge | DACK3        | O   | DMA transfer request acknowledge output from channel 3 to an external device |
| 0       | DMA transfer end                 | TEND0        | O   | DMA transfer end output for channel 0                                        |
| 1       | DMA transfer end                 | TEND1        | O   | DMA transfer end output for channel 1                                        |

## 10.3 Register Descriptions

The DMAC has the registers listed in table 10.2. There are four control registers and three reload registers for each channel, and one common control register is used by all channels. In addition, there is one extension resource selector per two channels. Each channel number is expressed in the register names, as in SAR\_0 for SAR in channel 0.

**Table 10.2 Register Configuration**

| Channel | Register Name                             | Abbreviation | R/W               | Initial Value | Address    | Access Size |
|---------|-------------------------------------------|--------------|-------------------|---------------|------------|-------------|
| 0       | DMA source address register_0             | SAR_0        | R/W               | H'00000000    | H'FFFE1000 | 16, 32      |
|         | DMA destination address register_0        | DAR_0        | R/W               | H'00000000    | H'FFFE1004 | 16, 32      |
|         | DMA transfer count register_0             | DMATCR_0     | R/W               | H'00000000    | H'FFFE1008 | 16, 32      |
|         | DMA channel control register_0            | CHCR_0       | R/W* <sup>1</sup> | H'00000000    | H'FFFE100C | 8, 16, 32   |
|         | DMA reload source address register_0      | RSAR_0       | R/W               | H'00000000    | H'FFFE1100 | 16, 32      |
|         | DMA reload destination address register_0 | RDAR_0       | R/W               | H'00000000    | H'FFFE1104 | 16, 32      |
|         | DMA reload transfer count register_0      | RDMATCR_0    | R/W               | H'00000000    | H'FFFE1108 | 16, 32      |
| 1       | DMA source address register_1             | SAR_1        | R/W               | H'00000000    | H'FFFE1010 | 16, 32      |
|         | DMA destination address register_1        | DAR_1        | R/W               | H'00000000    | H'FFFE1014 | 16, 32      |
|         | DMA transfer count register_1             | DMATCR_1     | R/W               | H'00000000    | H'FFFE1018 | 16, 32      |
|         | DMA channel control register_1            | CHCR_1       | R/W* <sup>1</sup> | H'00000000    | H'FFFE101C | 8, 16, 32   |
|         | DMA reload source address register_1      | RSAR_1       | R/W               | H'00000000    | H'FFFE1110 | 16, 32      |
|         | DMA reload destination address register_1 | RDAR_1       | R/W               | H'00000000    | H'FFFE1114 | 16, 32      |
|         | DMA reload transfer count register_1      | RDMATCR_1    | R/W               | H'00000000    | H'FFFE1118 | 16, 32      |

| Channel | Register Name                             | Abbreviation | R/W               | Initial Value | Address    | Access Size |
|---------|-------------------------------------------|--------------|-------------------|---------------|------------|-------------|
| 2       | DMA source address register_2             | SAR_2        | R/W               | H'00000000    | H'FFFE1020 | 16, 32      |
|         | DMA destination address register_2        | DAR_2        | R/W               | H'00000000    | H'FFFE1024 | 16, 32      |
|         | DMA transfer count register_2             | DMATCR_2     | R/W               | H'00000000    | H'FFFE1028 | 16, 32      |
|         | DMA channel control register_2            | CHCR_2       | R/W* <sup>1</sup> | H'00000000    | H'FFFE102C | 8, 16, 32   |
|         | DMA reload source address register_2      | RSAR_2       | R/W               | H'00000000    | H'FFFE1120 | 16, 32      |
|         | DMA reload destination address register_2 | RDAR_2       | R/W               | H'00000000    | H'FFFE1124 | 16, 32      |
|         | DMA reload transfer count register_2      | RDMATCR_2    | R/W               | H'00000000    | H'FFFE1128 | 16, 32      |
| 3       | DMA source address register_3             | SAR_3        | R/W               | H'00000000    | H'FFFE1030 | 16, 32      |
|         | DMA destination address register_3        | DAR_3        | R/W               | H'00000000    | H'FFFE1034 | 16, 32      |
|         | DMA transfer count register_3             | DMATCR_3     | R/W               | H'00000000    | H'FFFE1038 | 16, 32      |
|         | DMA channel control register_3            | CHCR_3       | R/W* <sup>1</sup> | H'00000000    | H'FFFE103C | 8, 16, 32   |
|         | DMA reload source address register_3      | RSAR_3       | R/W               | H'00000000    | H'FFFE1130 | 16, 32      |
|         | DMA reload destination address register_3 | RDAR_3       | R/W               | H'00000000    | H'FFFE1134 | 16, 32      |
|         | DMA reload transfer count register_3      | RDMATCR_3    | R/W               | H'00000000    | H'FFFE1138 | 16, 32      |

| Channel | Register Name                             | Abbreviation | R/W               | Initial Value | Address    | Access Size |
|---------|-------------------------------------------|--------------|-------------------|---------------|------------|-------------|
| 4       | DMA source address register_4             | SAR_4        | R/W               | H'00000000    | H'FFFE1040 | 16, 32      |

|         | DMA reload destination address register_7 | RDAR_7       | R/W               | H'00000000    | H'FFFE1174 | 16, 32      |
|         | DMA reload transfer count register_7      | RDMATCR_7    | R/W               | H'00000000    | H'FFFE1178 | 16, 32      |

| Channel | Register Name                     | Abbreviation | R/W               | Initial Value | Address    | Access Size |
|---------|-----------------------------------|--------------|-------------------|---------------|------------|-------------|
| Common  | DMA operation register            | DMAOR        | R/W* <sup>2</sup> | H'0000        | H'FFFE1200 | 8, 16       |
| 0 and 1 | DMA extension resource selector 0 | DMARS0       | R/W               | H'0000        | H'FFFE1300 | 16          |
| 2 and 3 | DMA extension resource selector 1 | DMARS1       | R/W               | H'0000        | H'FFFE1304 | 16          |
| 4 and 5 | DMA extension resource selector 2 | DMARS2       | R/W               | H'0000        | H'FFFE1308 | 16          |
| 6 and 7 | DMA extension resource selector 3 | DMARS3       | R/W               | H'0000        | H'FFFE130C | 16          |

- Notes:
1. For the HE and TE bits in CHCRn, only 0 can be written to clear the flags after 1 is read.
  2. For the AE and NMIF bits in DMAOR, only 0 can be written to clear the flags after 1 is read.

### 10.3.1 DMA Source Address Registers (SAR)

The DMA source address registers (SAR) are 32-bit readable/writable registers that specify the source address of a DMA transfer. During a DMA transfer, these registers indicate the next source address. When the data of an external device with DACK is transferred in single address mode, SAR is ignored.

To transfer data of 16-bit or 32-bit width, specify the address with 16-bit or 32-bit address boundary respectively. To transfer data in units of 16 bytes, set a value at a 16-byte boundary.

SAR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |

### 10.3.2 DMA Destination Address Registers (DAR)

The DMA destination address registers (DAR) are 32-bit readable/writable registers that specify the destination address of a DMA transfer. During a DMA transfer, these registers indicate the next destination address. When the data of an external device with DACK is transferred in single address mode, DAR is ignored.

To transfer data of 16-bit or 32-bit width, specify the address with 16-bit or 32-bit address boundary respectively. To transfer data in units of 16 bytes, set a value at a 16-byte boundary.

DAR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  |

### 10.3.3 DMA Transfer Count Registers (DMATCR)

The DMA transfer count registers (DMATCR) are 32-bit readable/writable registers that specify the number of DMA transfers. The transfer count is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. During a DMA transfer, these registers indicate the remaining transfer count.

The upper eight bits of DMATCR are always read as 0, and the write value should always be 0. To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one.

DMATCR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

### 10.3.4 DMA Channel Control Registers (CHCR)

The DMA channel control registers (CHCR) are 32-bit readable/writable registers that control DMA transfer mode.

The DO, AM, AL, DL, and DS bits which specify the DREQ and DACK external pin functions can be read and written to in channels 0 to 3, but they are reserved in channels 4 to 7. The TL bit which specifies the TEND external pin function can be read and written to in channels 0 and 1, but it is reserved in channels 2 to 7. Before modifying the CHCR setting, clear the DE bit for the corresponding channel.

CHCR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

| 0   | DE       | 0             | R/W    | <p>DMA Enable</p> <p>Enables or disables the DMA transfer. In auto-request mode, DMA transfer starts by setting the DE bit and DME bit in DMAOR to 1. In this case, all of the bits TE, NMIF in DMAOR, and AE must be 0. In an external request or peripheral module request, DMA transfer starts if DMA transfer request is generated by the devices or peripheral modules after setting the bits DE and DME to 1. In this case, however, all of the bits TE, NMIF, and AE must be 0 as in the case of auto-request mode. Clearing the DE bit to 0 can terminate the DMA transfer. Before modifying the CHCR setting, clear the DE bit to 0 for the corresponding channel.</p> <p>0: DMA transfer disabled</p> <p>1: DMA transfer enabled</p>                                                                     |

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 10.3.5 DMA Reload Source Address Registers (RSAR)

The DMA reload source address registers (RSAR) are 32-bit readable/writable registers.

When the reload function is enabled, the RSAR value is written to the source address register (SAR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RSAR during the current DMA transfer. When the reload function is disabled, RSAR is ignored.

To transfer data of 16-bit or 32-bit width, specify the address with 16-bit or 32-bit address boundary respectively. To transfer data in units of 16 bytes, set a value at a 16-byte boundary.

RSAR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

### 10.3.6 DMA Reload Destination Address Registers (RDAR)

The DMA reload destination address registers (RDAR) are 32-bit readable/writable registers.

When the reload function is enabled, the RDAR value is written to the destination address register (DAR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RDAR during the current DMA transfer. When the reload function is disabled, RDAR is ignored.

To transfer data of 16-bit or 32-bit width, specify the address with 16-bit or 32-bit address boundary respectively. To transfer data in units of 16 bytes, set a value at a 16-byte boundary.

RDAR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

### 10.3.7 DMA Reload Transfer Count Registers (RDMATCR)

The DMA reload transfer count registers (RDMATCR) are 32-bit readable/writable registers.

When the reload function is enabled, the RDMATCR value is written to the transfer count register (DMATCR) at the end of the current DMA transfer. In this case, a new value for the next DMA transfer can be preset in RDMATCR during the current DMA transfer. When the reload function is disabled, RDMATCR is ignored.

The upper eight bits of RDMATCR are always read as 0, and the write value should always be 0.

As in DMATCR, the transfer count is 1 when the setting is H'00000001, 16,777,215 when H'00FFFFFF is set, and 16,777,216 (the maximum) when H'00000000 is set. To transfer data in 16 bytes, one 16-byte transfer (128 bits) counts one.

RDMATCR is initialized to H'00000000 by a reset and retains the value in software standby mode and module standby mode.

### 10.3.8 DMA Operation Register (DMAOR)

The DMA operation register (DMAOR) is a 16-bit readable/writable register that specifies the priority level of channels at the DMA transfer. This register also shows the DMA transfer status.

DMAOR is initialized to H'0000 by a reset and retains the value in software standby mode and module standby mode.

|-----|----------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | DME      | 0             | R/W | <p>DMA Master Enable</p> <p>Enables or disables DMA transfer on all channels. If the DME bit and DE bit in CHCR are set to 1, DMA transfer is enabled.</p> <p>However, transfer is enabled only when the TE bit in CHCR of the transfer corresponding channel, the NMIF bit in DMAOR, and the AE bit are all cleared to 0. Clearing the DME bit to 0 can terminate the DMA transfer on all channels.</p> <p>0: DMA transfer is disabled on all channels<br/>1: DMA transfer is enabled on all channels</p> |

Note: \* To clear the flag, write 0 after having read the flag as 1. Write 1 after having read the flag as 0. Only 0 can be written after 1 is read.

If the priority mode bits are modified after a DMA transfer, the channel priority is initialized. If fixed mode 2 is specified, the channel priority is specified as CH0 > CH4 > CH1 > CH5 > CH2 > CH6 > CH3 > CH7. If fixed mode 1 is specified, the channel priority is specified as CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7. If round-robin mode is specified, the transfer end channel is reset.

Table 10.3 show the priority change in each mode (modes 0 to 2) specified by the priority mode bits. In each priority mode, the channel priority to accept the next transfer request may change in up to three ways according to the transfer end channel.

For example, when the transfer end channel is channel 1, the priority of the channel to accept the next transfer request is specified as CH2 > CH3 > CH0 > CH1 > CH4 > CH5 > CH6 > CH7. When the transfer end channel is any one of the channels 4 to 7, round-robin will not be applied and the priority level is not changed at the end of transfer in the channels 4 to 7.

The DMAC internal operation for an address error is as follows:

- No address error: Read (source to DMAC) → Write (DMAC to destination)
- Address error in source address: Nop → Nop
- Address error in destination address: Read → Nop

**Table 10.3 Combinations of Priority Mode Bits**

| Mode                         | Transfer End | Priority Mode Bits |       | Priority Level at the End of Transfer |     |     |     |     |     |     |     |
|------------------------------|--------------|--------------------|-------|---------------------------------------|-----|-----|-----|-----|-----|-----|-----|

### 10.3.9 DMA Extension Resource Selectors 0 to 3 (DMARS0 to DMARS3)

The DMA extension resource selectors (DMARS) are 16-bit readable/writable registers that specify the DMA transfer sources from peripheral modules in each channel. DMARS0 is for channels 0 and 1, DMARS1 is for channels 2 and 3, DMARS2 is for channels 4 and 5, and DMARS3 is for channels 6 and 7. Table 10.4 shows the specifiable combinations.

DMARS can specify transfer requests from two USB sources, one RCAN source, two SSU sources, two SCIF sources, two IIC3 sources, one A/D converter source, five MTU2 sources, two CMT sources, four USB sources, one RCAN-ET source, and two RSPI sources.

DMARS is initialized to H'0000 by a reset and retains the value in software standby mode and module standby mode.

When MID or RID other than the values listed in table 10.4 is set, the operation of this LSI is not guaranteed. The transfer request from DMARS is valid only when the resource select bits (RS[3:0]) in CHCR0 to CHCR7 have been set to B'1000. Otherwise, even if DMARS has been set, the transfer request source is not accepted.

## 10.4 Operation

When there is a DMA transfer request, the DMAC starts the transfer according to the predetermined channel priority order; when the transfer end conditions are satisfied, it ends the transfer. Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. In bus mode, burst mode or cycle steal mode can be selected.

### 10.4.1 Transfer Flow

After the DMA source address registers (SAR), DMA destination address registers (DAR), DMA transfer count registers (DMATCR), DMA channel control registers (CHCR), DMA operation register (DMAOR), and DMA extension resource selector (DMARS) are set for the target transfer conditions, the DMAC transfers data according to the following procedure:

1. Checks to see if transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0)
2. When a transfer request comes and transfer is enabled, the DMAC transfers one transfer unit of data (depending on the TS0 and TS1 settings). For an auto request, the transfer begins automatically when the DE bit and DME bit are set to 1. The DMATCR value will be decremented by 1 for each transfer. The actual transfer flows vary by address mode and bus mode.
3. When half of the specified transfer count is exceeded (when DMATCR reaches half of the initial value), an HEI interrupt is sent to the CPU if the HIE bit in CHCR is set to 1.
4. When transfer has been completed for the specified count (when DMATCR reaches 0), the transfer ends normally. If the IE bit in CHCR is set to 1 at this time, a DEI interrupt is sent to the CPU.
5. When an address error in the DMAC or an NMI interrupt is generated, the transfer is terminated. Transfers are also terminated when the DE bit in CHCR or the DME bit in DMAOR is cleared to 0.

Figure 10.2 is a flowchart of this procedure.

- Notes: 1. In auto-request mode, transfer begins when the NMIF, AE, and TE bits are cleared to 0 and the DE and DME bits are set to 1.  
 2. DREQ level detection in burst mode (external request) or cycle steal mode.  
 3. DREQ edge detection in burst mode (external request), or auto request mode in burst mode.

Figure 10.2 DMA Transfer Flowchart

## 10.4.2 DMA Transfer Requests

DMA transfer requests are basically generated in either the data transfer source or destination, but they can also be generated in external devices and on-chip peripheral modules that are neither the transfer source nor destination.

Transfers can be requested in three modes: auto request, external request, and on-chip peripheral module request. The request mode is selected by the RS[3:0] bits in CHCR\_0 to CHCR\_7 and DMARS0 to DMARS3.

### (1) Auto-Request Mode

When there is no transfer request signal from an external source, as in a memory-to-memory transfer or a transfer between memory and an on-chip peripheral module unable to request a transfer, auto-request mode allows the DMAC to automatically generate a transfer request signal internally. When the DE bits in CHCR\_0 to CHCR\_7 and the DME bit in DMAOR are set to 1, the transfer begins so long as the TE bits in CHCR\_0 to CHCR\_7, and the AE and NMIF bits in DMAOR are 0.

### (2) External Request Mode

In this mode a transfer is performed at the request signals (DREQ0 to DREQ3) of an external device. Choose one of the modes shown in table 10.5 according to the application system. When the DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, NMIF = 0), DMA transfer is performed upon a request at the DREQ input.

**Table 10.5 Selecting External Request Modes with the RS Bits**

| RS[3] | RS[2] | RS[1] | RS[0] | Address Mode        | Transfer Source                                | Transfer Destination                           |
|-------|-------|-------|-------|---------------------|------------------------------------------------|------------------------------------------------|
| 0     | 0     | 0     | 0     | Dual address mode   | Any                                            | Any                                            |
| 0     | 0     | 1     | 0     | Single address mode | External memory, memory-mapped external device | External device with DACK                      |
|       |       |       | 1     |                     | External device with DACK                      | External memory, memory-mapped external device |

Choose to detect DREQ by either the edge or level of the signal input with the DL and DS bits in CHCR\_0 to CHCR\_3 as shown in table 10.6. The source of the transfer request does not have to be the data transfer source or destination.

**Table 10.6 Selecting External Request Detection with DL and DS Bits**

| <b>CHCR</b>   |               |                                      |
|---------------|---------------|--------------------------------------|
| <b>DL bit</b> | <b>DS bit</b> | <b>Detection of External Request</b> |
| 0             | 0             | Low level detection                  |
|               | 1             | Falling edge detection               |
| 1             | 0             | High level detection                 |
|               | 1             | Rising edge detection                |

When DREQ is accepted, the DREQ pin enters the request accept disabled state (non-sensitive period). After issuing acknowledge DACK signal for the accepted DREQ, the DREQ pin again enters the request accept enabled state.

When DREQ is used by level detection, there are following two cases by the timing to detect the next DREQ after outputting DACK.

Overrun 0: Transfer is terminated after the same number of transfer has been performed as requests.

Overrun 1: Transfer is terminated after transfers have been performed for (the number of requests plus 1) times.

The DO bit in CHCR selects this overrun 0 or overrun 1.

**Table 10.7 Selecting External Request Detection with DO Bit**

| <b>CHCR</b>   |                         |
|---------------|-------------------------|
| <b>DO bit</b> | <b>External Request</b> |
| 0             | Overrun 0               |
| 1             | Overrun 1               |

### (3) On-Chip Peripheral Module Request

In this mode, the transfer is performed in response to the DMA transfer request signal from an on-chip peripheral module.

DMA transfer request signals from on-chip peripheral modules to the DMAC include transmit data empty and receive data full requests from the SCIF, A/D conversion end request from the A/D converter, compare match request from the CMT, and data transfer requests from the IIC3, MTU2, USB, RCAN-ET, and RSPI.

When a transfer request signal is sent in on-chip peripheral module request mode while DMA transfer is enabled (DE = 1, DME = 1, TE = 0, AE = 0, and NMIF = 0), DMA transfer is performed.

When the transmit data empty from the SCIF is selected, specify the transfer destination as the corresponding SCIF transmit data register. Likewise, when the receive data full from the SCIF is selected, specify the transfer source as the corresponding SCIF receive data register. When a transfer request is made by the A/D converter, the transfer source must be the A/D data register (ADDR). When the IIC3 transmission is selected as the transfer request, the transfer destination must be ICDRT; when the IIC3 reception is selected as the transfer request, the transfer source must be ICDRR. When the USB transmission is selected as the transfer request, the transfer destination must be the data registers (USBEPDR2 and USBEPDR5) for the corresponding endpoint; when the USB reception is selected as the transfer request, the transfer source must be the data registers (USBEPDR1 and USBEPDR4) for the corresponding endpoint. When the RSPI transmission is selected as the transfer request, the transfer destination must be the RSPI data register (SPDR); when the RSPI reception is selected as the transfer request, the transfer source must be the RSPI data register (SPDR). When the RCAN-ET receive interrupt is selected as the transfer request, the transfer source must be a mailbox (MB0 to MB15). Any address can be specified for data transfer source and destination when a transfer request is sent from the CMT or MTU2.

**Table 10.8 Selecting On-Chip Peripheral Module Request Modes with RS3 to RS0 Bits**

| CHCR<br>RS[3:0] | DMARS  |     | DMA Transfer<br>Request Source | DMA Transfer<br>Request Signal   | Transfer<br>Source        | Transfer<br>Destination | Bus<br>Mode                        |
|-----------------|--------|-----|--------------------------------|----------------------------------|---------------------------|-------------------------|------------------------------------|
|                 | MID    | RID |                                |                                  |                           |                         |                                    |
| 1000            | 100000 | 01  | USB transmit                   | EP2 FIFO empty transfer request  | Any                       | USBEPDR2                | Cycle steal                        |
|                 |        | 10  | USB receive                    | EP1 FIFO full transfer request   | USBEPDR1                  | Any                     |                                    |
|                 | 100001 | 10  | RCAN-ET                        | RM0 (RCAN-ET receive interrupt)  | MB0 to MB15* <sup>1</sup> | Any                     | Cycle steal                        |
|                 | 100010 | 01  | RSPI transmit                  | SPTI (transmit data empty)       | Any                       | SPDR                    | Cycle steal or burst* <sup>2</sup> |
|                 |        | 10  | RSPI receive                   | SPRI (receive data full)         | SPDR                      | Any                     |                                    |
|                 | 100011 | 01  | SCIF_3 transmit                | TXI3 (transmit FIFO data empty)  | Any                       | SCFTDR3                 | Cycle steal                        |
|                 |        | 10  | SCIF_3 receive                 | RXI3 (receive FIFO data full)    | SCFRDR3                   | Any                     |                                    |
|                 | 100100 | 01  | USB transmit                   | EP5 FIFO empty transfer request  | Any                       | USBEPDR5                | Cycle steal                        |
|                 |        | 10  | USB receive                    | EP4 FIFO full transfer request   | USBEPDR4                  | Any                     |                                    |
|                 | 101000 | 01  | IIC3 transmit                  | TXI (transmit data empty)        | Any                       | ICDRT                   | Cycle steal                        |
|                 |        | 10  | IIC3 receive                   | RXI (receive data full)          | ICDRR                     | Any                     |                                    |
|                 | 101100 | 11  | A/D converter_0                | ADI0 (A/D conversion end)        | ADDR0 to ADDR3            | Any                     | Cycle steal                        |
|                 | 111000 | 11  | MTU2_0                         | TGIA_0                           | Any                       | Any                     | Cycle steal or burst               |
|                 | 111001 | 11  | MTU2_1                         | TGIA_1                           | Any                       | Any                     |                                    |
|                 | 111010 | 11  | MTU2_2                         | TGIA_2                           | Any                       | Any                     |                                    |
|                 | 111011 | 11  | MTU2_3                         | TGIA_3                           | Any                       | Any                     |                                    |
|                 | 111100 | 11  | MTU2_4                         | TGIA_4                           | Any                       | Any                     |                                    |
|                 | 111110 | 11  | CMT_0                          | Compare match transmit request 0 | Any                       | Any                     | Cycle steal or burst               |
|                 | 111111 | 11  | CMT_1                          | Compare match transmit request 1 | Any                       | Any                     |                                    |

Notes: 1. Transfer count mode can be used to read message control fields 1 to 2 in a mailbox.  
 2. To set to burst mode, see section 18.5.2, DMAC Burst Transfer.

### 10.4.3 Channel Priority

When the DMAC receives simultaneous transfer requests on two or more channels, it selects a channel according to a predetermined priority order. Three modes (fixed mode 1, fixed mode 2, and round-robin mode) are selected using the PR1 and PR0 bits in DMAOR.

#### (1) Fixed Mode

In fixed modes, the priority levels among the channels remain fixed. There are two kinds of fixed modes as follows:

Fixed mode 1: CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7

Fixed mode 2: CH0 > CH4 > CH1 > CH5 > CH2 > CH6 > CH3 > CH7

These are selected by the PR1 and PR0 bits in the DMA operation register (DMAOR).

#### (2) Round-Robin Mode

Each time one unit of word, byte, longword, or 16 bytes is transferred on one channel, the priority order is rotated. The channel on which the transfer was just finished is rotated to the lowest of the priority order among the four round-robin channels (channels 0 to 4). The priority of the channels other than the round-robin channels (channels 0 to 4) does not change even in round-robin mode. The round-robin mode operation is shown in figure 10.3. The priority in round-robin mode is CH0 > CH1 > CH2 > CH3 > CH4 > CH5 > CH6 > CH7 immediately after a reset.

When round-robin mode has been specified, do not concurrently specify cycle steal mode and burst mode as the bus modes of any two or more channels.

## (1) When channel 0 transfers

## (2) When channel 1 transfers

## (3) When channel 2 transfers

## (4) When channel 7 transfers

**Figure 10.3 Round-Robin Mode**

Figure 10.4 shows how the priority order changes when channel 0 and channel 3 transfers are requested simultaneously and a channel 1 transfer is requested during the channel 0 transfer. The DMAC operates as follows:

1. Transfer requests are generated simultaneously to channels 0 and 3.
2. Channel 0 has a higher priority, so the channel 0 transfer begins first (channel 3 waits for transfer).
3. A channel 1 transfer request occurs during the channel 0 transfer (channels 1 and 3 are both waiting)
4. When the channel 0 transfer ends, channel 0 is given the lowest priority among the round-robin channels.
5. At this point, channel 1 has a higher priority than channel 3, so the channel 1 transfer begins (channel 3 waits for transfer).
6. When the channel 1 transfer ends, channel 1 is given the lowest priority among the round-robin channels.
7. The channel 3 transfer begins.
8. When the channel 3 transfer ends, channels 3 and 2 are lowered in priority so that channel 3 is given the lowest priority among the round-robin channels.

**Figure 10.4 Changes in Channel Priority in Round-Robin Mode**

### 10.4.4 DMA Transfer Types

DMA transfer has two types: single address mode transfer and dual address mode transfer. They depend on the number of bus cycles of access to the transfer source and destination. A data transfer timing depends on the bus mode, which is cycle steal mode or burst mode. The DMAC supports the transfers shown in table 10.9.

**Table 10.9 Supported DMA Transfers**

| Transfer Source               | Transfer Destination      |                 |                               |                           |                |
|-------------------------------|---------------------------|-----------------|-------------------------------|---------------------------|----------------|
|                               | External Device with DACK | External Memory | Memory-Mapped External Device | On-Chip Peripheral Module | On-Chip Memory |
| External device with DACK     | Not available             | Dual, single    | Dual, single                  | Not available             | Not available  |
| External memory               | Dual, single              | Dual            | Dual                          | Dual                      | Dual           |
| Memory-mapped external device | Dual, single              | Dual            | Dual                          | Dual                      | Dual           |
| On-chip peripheral module     | Not available             | Dual            | Dual                          | Dual                      | Dual           |
| On-chip memory                | Not available             | Dual            | Dual                          | Dual                      | Dual           |

Notes: 1. Dual: Dual address mode  
 2. Single: Single address mode  
 3. 16-byte transfer is available only for on-chip peripheral modules that support longword access.

## (1) Address Modes

### (a) Dual Address Mode

In dual address mode, both the transfer source and destination are accessed (selected) by an address. The transfer source and destination can be located externally or internally.

DMA transfer requires two bus cycles because data is read from the transfer source in a data read cycle and written to the transfer destination in a data write cycle. At this time, transfer data is temporarily stored in the DMAC. In the transfer between external memories as shown in figure 10.5, data is read to the DMAC from one external memory in a data read cycle, and then that data is written to the other external memory in a data write cycle.

**Figure 10.5 Data Flow of Dual Address Mode**

Auto request, external request, and on-chip peripheral module request are available for the transfer request. DACK can be output in read cycle or write cycle in dual address mode. The AM bit in the channel control register (CHCR) can specify whether the DACK is output in read cycle or write cycle.

Figure 10.6 shows an example of DMA transfer timing in dual address mode.

**Figure 10.6 Example of DMA Transfer Timing in Dual Mode**  
**(Transfer Source: Normal Memory, Transfer Destination: Normal Memory)**

## (b) Single Address Mode

In single address mode, both the transfer source and destination are external devices, either of them is accessed (selected) by the DACK signal, and the other device is accessed by an address. In this mode, the DMAC performs one DMA transfer in one bus cycle, accessing one of the external devices by outputting the DACK transfer request acknowledge signal to it, and at the same time outputting an address to the other device involved in the transfer. For example, in the case of transfer between external memory and an external device with DACK shown in figure 10.7, when the external device outputs data to the data bus, that data is written to the external memory in the same bus cycle.

**Figure 10.7 Data Flow in Single Address Mode**

Two kinds of transfer are possible in single address mode: (1) transfer between an external device with DACK and a memory-mapped external device, and (2) transfer between an external device with DACK and external memory. In both cases, only the external request signal (DREQ) is used for transfer requests.

Figure 10.8 shows an example of DMA transfer timing in single address mode.

**Figure 10.8 Example of DMA Transfer Timing in Single Address Mode**

## (2) Bus Modes

There are two bus modes; cycle steal and burst. Select the mode by the TB bits in the channel control registers (CHCR).

### (a) Cycle Steal Mode

- Normal mode

In normal mode of cycle steal, the bus mastership is given to another bus master after a one-transfer-unit (byte, word, longword, or 16-byte unit) DMA transfer. When another transfer request occurs, the bus mastership is obtained from another bus master and a transfer is performed for one transfer unit. When that transfer ends, the bus mastership is passed to another bus master. This is repeated until the transfer end conditions are satisfied.

The cycle-steal normal mode can be used for any transfer section; transfer request source, transfer source, and transfer destination.

Figure 10.9 shows an example of DMA transfer timing in cycle-steal normal mode. Transfer conditions shown in the figure are:

- Dual address mode
- DREQ low level detection

**Figure 10.9 DMA Transfer Example in Cycle-Steal Normal Mode  
(Dual Address, DREQ Low Level Detection)**

- Intermittent Mode 16 and Intermittent Mode 64

In intermittent mode of cycle steal, DMAC returns the bus mastership to other bus master whenever a unit of transfer (byte, word, longword, or 16 bytes) is completed. If the next transfer request occurs after that, DMAC obtains the bus mastership from other bus master after waiting for 16 or 64 cycles of B $\phi$  clock. DMAC then transfers data of one unit and returns the bus mastership to other bus master. These operations are repeated until the transfer end condition is satisfied. It is thus possible to make lower the ratio of bus occupation by DMA transfer than normal mode of cycle steal.

The cycle-steal intermittent mode can be used for any transfer section; transfer request source, transfer source, and transfer destination. The bus modes, however, must be cycle steal mode in all channels.

Figure 10.10 shows an example of DMA transfer timing in cycle-steal intermittent mode. Transfer conditions shown in the figure are:

- Dual address mode
- DREQ low level detection

**Figure 10.10 Example of DMA Transfer in Cycle-Steal Intermittent Mode  
(Dual Address, DREQ Low Level Detection)**

**(b) Burst Mode**

In burst mode, once the DMAC obtains the bus mastership, it does not release the bus mastership and continues to perform transfer until the transfer end condition is satisfied. In external request mode with low level detection of the DREQ pin, however, when the DREQ pin is driven high, the bus mastership is passed to another bus master after the DMAC transfer request that has already been accepted ends, even if the transfer end conditions have not been satisfied.

Figure 10.11 shows DMA transfer timing in burst mode.

**Figure 10.11 DMA Transfer Example in Burst Mode  
(Dual Address, DREQ Low Level Detection)**

### (3) Relationship between Request Modes and Bus Modes by DMA Transfer Category

Table 10.10 shows the relationship between request modes and bus modes by DMA transfer category.

**Table 10.10 Relationship of Request Modes and Bus Modes by DMA Transfer Category**

| Address Mode | Transfer Category                                               | Request Mode      | Bus Mode          | Transfer Size (Bits)      | Usable Channels      |
|--------------|-----------------------------------------------------------------|-------------------|-------------------|---------------------------|----------------------|
| Dual         | External device with DACK and external memory                   | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External device with DACK and memory-mapped external device     | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External memory and external memory                             | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | External memory and memory-mapped external device               | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | Memory-mapped external device and memory-mapped external device | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | External memory and on-chip peripheral module                   | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | Memory-mapped external device and on-chip peripheral module     | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip peripheral module and on-chip peripheral module         | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip memory and on-chip memory                               | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | On-chip memory and memory-mapped external device                | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
|              | On-chip memory and on-chip peripheral module                    | All* <sup>1</sup> | B/C* <sup>5</sup> | 8/16/32/128* <sup>2</sup> | 0 to 7* <sup>3</sup> |
|              | On-chip memory and external memory                              | All* <sup>4</sup> | B/C               | 8/16/32/128               | 0 to 7* <sup>3</sup> |
| Single       | External device with DACK and external memory                   | External          | B/C               | 8/16/32/128               | 0 to 3               |
|              | External device with DACK and memory-mapped external device     | External          | B/C               | 8/16/32/128               | 0 to 3               |

[Legend]

B: Burst

C: Cycle steal

- Notes:
1. External requests, auto requests, and on-chip peripheral module requests are all available. However, along with the exception of CMT and MTU2 as the transfer request source, the requesting module must be designated as the transfer source or the transfer destination.
  2. Access size permitted for the on-chip peripheral module register functioning as the transfer source or transfer destination.
  3. If the transfer request is an external request, channels 0 to 3 are only available.
  4. External requests, auto requests, and on-chip peripheral module requests are all available. In the case of on-chip peripheral module requests, however, the CMT and MTU2 are only available.
  5. Only cycle steal except for the RSPI, MTU2, and CMT as the transfer request source.

#### (4) Bus Mode and Channel Priority

In priority fixed mode ( $CH0 > CH1$ ), when channel 1 is transferring data in burst mode and a request arrives for transfer on channel 0, which has higher-priority, the data transfer on channel 0 will begin immediately. In this case, if the transfer on channel 0 is also in burst mode, the transfer on channel 1 will only resume on completion of the transfer on channel 0.

When channel 0 is in cycle steal mode, one transfer-unit of data on this channel, which has the higher priority, is transferred. Data is then transferred continuously to channel 1 without releasing the bus. The bus mastership will then switch between the two in this order: channel 0, channel 1, channel 0, channel 1, etc. That is, the CPU cycle after the data transfer in cycle steal mode is replaced with a burst-mode transfer cycle (priority execution of burst-mode cycle). An example of this is shown in figure 10.12.

When multiple channels are in burst mode, data transfer on the channel that has the highest priority is given precedence. When DMA transfer is being performed on multiple channels, the bus mastership is not released to another bus-master device until all of the competing burst-mode transfers have been completed.

**Figure 10.12 Bus State when Multiple Channels are Operating**

In round-robin mode, the priority changes as shown in figure 10.3. Note that channels in cycle steal and burst modes must not be mixed.

## 10.4.5 Number of Bus Cycles and DREQ Pin Sampling Timing

### (1) Number of Bus Cycles

When the DMAC is the bus master, the number of bus cycles is controlled by the bus state controller (BSC) in the same way as when the CPU is the bus master. For details, see section 9, Bus State Controller (BSC).

### (2) DREQ Pin Sampling Timing

Figures 10.13 to 10.16 show the DREQ input sampling timings in each bus mode.

**Figure 10.13 Example of DREQ Input Detection in Cycle Steal Mode Edge Detection**

**Figure 10.14 Example of DREQ Input Detection in Cycle Steal Mode Level Detection**

**Figure 10.15 Example of DREQ Input Detection in Burst Mode Edge Detection**

**Figure 10.16 Example of DREQ Input Detection in Burst Mode Level Detection**

Figure 10.17 shows the TEND output timing.

**Figure 10.17 Example of DMA Transfer End Signal Timing  
(Cycle Steal Mode Level Detection)**

The unit of the DMA transfer is divided into multiple bus cycles when 16-byte transfer is performed for an 8-bit or 16-bit external device, when longword access is performed for an 8-bit or 16-bit external device, or when word access is performed for an 8-bit external device. When a setting is made so that the DMA transfer size is divided into multiple bus cycles and the  $\overline{CS}$  signal is negated between bus cycles, note that DACK and TEND are divided like the  $\overline{CS}$  signal for data alignment. Also, if the DREQ detection is set to level-detection mode (DS bit in CHCR = 0), the DREQ sampling may not be detected correctly with divided DACK, and one extra overrun may occur at maximum.

Use a setting that does not divide DACK or specify a transfer size smaller than the external device bus width if DACK is divided. Figure 10.18 shows this example.

Note:  $\overline{TEND}$  is asserted for the last unit of DMA transfer. If a transfer unit is divided into multiple bus cycles and the  $\overline{CS}$  is negated between the bus cycles,  $\overline{TEND}$  is also divided.

(No Wait, Idle Cycle 1, Longword Access to 16-Bit Device)

## 10.5 Interrupt Sources

### 10.5.1 Interrupt Sources and Priority Order

The interrupt sources of the DMAC are the data transfer end interrupt (DEI) and data transfer half-end interrupt (HEI) for each channel. Table 10.11 lists the interrupt sources and their order of priority.

The IE and HIE bits in the DMA channel control registers (CHCRs) enable or disable the respective interrupt sources. Furthermore, the interrupt requests are independently conveyed to the interrupt controller.

A data-transfer end interrupt (DEI) is generated when, the transfer end flag and the transfer end interrupt enable (IE) bit in the DMA channel control register (CHCR) are set to 1. A data-transfer half end interrupt (HEI) is generated when the half-end flag and the half-end interrupt enable (HIE) bit in the DMA channel control register (CHCR) are set to 1. Clearing the interrupt flag bit to 0 cancels the interrupt request.

Priority among the channels is adjustable by the interrupt controller. The order of priority for interrupts of a given channel is fixed. For details, refer to section 6, Interrupt Controller (INTC).

**Table 10.11 Interrupt Sources**

| Channel | Interrupt Source                        | Interrupt Enable Bit | Interrupt Flag | Priority                                                                                    |
|---------|-----------------------------------------|----------------------|----------------|---------------------------------------------------------------------------------------------|
| 0       | Data transfer end interrupt (DEI0)      | IE                   | TE             | <br>High |
|         | Data transfer half end interrupt (HEI0) | HIE                  | HE             |                                                                                             |
| 1       | Data transfer end interrupt (DEI1)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI1) | HIE                  | HE             |                                                                                             |
| 2       | Data transfer end interrupt (DEI2)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI2) | HIE                  | HE             |                                                                                             |
| 3       | Data transfer end interrupt (DEI3)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI3) | HIE                  | HE             |                                                                                             |
| 4       | Data transfer end interrupt (DEI4)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI4) | HIE                  | HE             |                                                                                             |
| 5       | Data transfer end interrupt (DEI5)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI5) | HIE                  | HE             |                                                                                             |
| 6       | Data transfer end interrupt (DEI6)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI6) | HIE                  | HE             |                                                                                             |
| 7       | Data transfer end interrupt (DEI7)      | IE                   | TE             |                                                                                             |
|         | Data transfer half end interrupt (HEI7) | HIE                  | HE             | Low                                                                                         |

## 10.6 Usage Notes

### 10.6.1 Setting of the Half-End Flag and the Half-End Interrupt

Since the following points for caution apply in cases where reference to the state of the half-end flag in the CHCR register or the half-end interrupt is used in conjunction with the reload function, please take care on these points.

Ensure that the reloaded number of transfers (the value set in RDMATCR) is always the same as the number of transfers that was initially set (the value set in DMATCR). If the initial setting in DMATCR and the value for the second and later transfers in RDMATCR are different, the timing with which the half-end flag is set may be faster than half the number of transfers, or the half-end flag might not be set at all. The same considerations apply to the half-end interrupt.

### 10.6.2 Timing of DACK and TEND Outputs

When the external memory is MPX-I/O or burst MPX-I/O, assertion of the DACK output has the same timing as the data cycle. For details, see the respective figures under section 9.5.5, MPX-I/O Interface, in section 9, Bus State Controller (BSC).

When the memory is other than the MPX-I/O or burst MPX-I/O, the DACK output is asserted with the same timing as the corresponding CS signal.

The TEND output does not depend on the type of memory and is always asserted with the same timing as the corresponding CS signal.

### 10.6.3 CHCR Setting

When changing the CHCR setting, the DE bit of the relevant channel must be cleared before the change.

### 10.6.4 Note on Activation of Multiple Channels

The same internal request must not be set to more than one channel.

### 10.6.5 Note on Transfer Request Input

A transfer request should be input after the DMAC settings have been made.

### 10.6.6 Conflict between NMI Interrupt and DMAC Activation

When a conflict occurs between the generation of the NMI interrupt and the DMAC activation, the NMI interrupt has priority. Thus the NMIF bit is set to 1 and the DMAC is not activated.

It takes  $2 \times \text{Bcyc}$  or  $3 \times \text{Pcyc}$  for checking DMAC stop by the NMI,  $4 \times \text{Bcyc}$  for checking DMAC activation by the DREQ, and  $1 \times \text{Bcyc} + 1 \times \text{Pcyc}$  for checking DMAC activation by a peripheral module (Bcyc indicates the cycle of the external bus clock, Pcyc indicates the cycle of the peripheral clock).

### 10.6.7 Number of On-Chip RAM Access Cycles from DMAC

The number of on-chip RAM access cycles from the DMAC becomes the number of cycles shown in table 10.12, depending on whether the operation is read or write and the clock ratio between  $I\phi$  (internal clock) and  $B\phi$  (external bus clock).

**Table 10.12 Number of On-Chip RAM Access Cycles from DMAC**

| Setting of $I\phi:B\phi$ | Read Operation         | Write Operation        |
|--------------------------|------------------------|------------------------|
| 1:1                      | $3 \times \text{Bcyc}$ | $2 \times \text{Bcyc}$ |
| 1:1/2                    | $2 \times \text{Bcyc}$ | $2 \times \text{Bcyc}$ |
| 1:1/4                    | $2 \times \text{Bcyc}$ | $2 \times \text{Bcyc}$ |
| Smaller than 1:1/4       | $1 \times \text{Bcyc}$ | $1 \times \text{Bcyc}$ |

Note: Bcyc indicates the cycle of the external bus clock.

## Section 11 Multi-Function Timer Pulse Unit 2 (MTU2)

This LSI has an on-chip multi-function timer pulse unit 2 (MTU2) that comprises six 16-bit timer channels.

### 11.1 Features

- Maximum 16 pulse input/output lines and three pulse input lines
- Selection of eight counter input clocks for each channel (four clocks for channel 5)
- The following operations can be set for channels 0 to 4:
  - Waveform output at compare match
  - Input capture function
  - Counter clear operation
  - Multiple timer counters (TCNT) can be written to simultaneously
  - Simultaneous clearing by compare match and input capture is possible
  - Register simultaneous input/output is possible by synchronous counter operation
  - A maximum 12-phase PWM output is possible in combination with synchronous operation.
- Buffer operation settable for channels 0, 3, and 4
- Phase counting mode settable independently for each of channels 1 and 2
- Cascade connection operation
- Fast access via internal 16-bit bus
- 28 interrupt sources
- Automatic transfer of register data
- A/D converter start trigger can be generated
- Module standby mode can be settable
- A total of six-phase waveform output, which includes complementary PWM output, and positive and negative phases of reset PWM output by interlocking operation of channels 3 and 4, is possible.
- AC synchronous motor (brushless DC motor) drive mode using complementary PWM output and reset PWM output is settable by interlocking operation of channels 0, 3, and 4, and the selection of two types of waveform outputs (chopping and level) is possible.
- Dead time compensation counter available in channel 5
- In complementary PWM mode, interrupts at the crest and trough of the counter value and A/D converter start triggers can be skipped.

**Table 11.1 MTU2 Functions**

| Item                                   | Channel 0                            | Channel 1                            | Channel 2                            | Channel 3                            | Channel 4                            | Channel 5                            |
|----------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| Count clock                            | P $\phi$ /1                          | P $\phi$ /1                          | P $\phi$ /1                          | P $\phi$ /1                          | P $\phi$ /1                          | P $\phi$ /1                          |
|                                        | P $\phi$ /4                          | P $\phi$ /4                          | P $\phi$ /4                          | P $\phi$ /4                          | P $\phi$ /4                          | P $\phi$ /4                          |
|                                        | P $\phi$ /16                         | P $\phi$ /16                         | P $\phi$ /16                         | P $\phi$ /16                         | P $\phi$ /16                         | P $\phi$ /16                         |

## 11.3 Register Descriptions

The MTU2 has the following registers. For details on register addresses and register states during each process, refer to section 32, List of Registers. To distinguish registers in each channel, an underscore and the channel number are added as a suffix to the register name; TCR for channel 0 is expressed as TCR\_0.

**Table 11.3 Register Descriptions**

| Register Name                       | Abbrevia-<br>tion | R/W | Initial<br>value | Address    | Access<br>Size |
|-------------------------------------|-------------------|-----|------------------|------------|----------------|
| Timer control register_3            | TCR_3             | R/W | H'00             | H'FFFE4200 | 8, 16, 32      |
| Timer control register_4            | TCR_4             | R/W | H'00             | H'FFFE4201 | 8              |
| Timer mode register_3               | TMDR_3            | R/W | H'00             | H'FFFE4202 | 8, 16          |
| Timer mode register_4               | TMDR_4            | R/W | H'00             | H'FFFE4203 | 8              |
| Timer I/O control register H_3      | TIORH_3           | R/W | H'00             | H'FFFE4204 | 8, 16, 32      |
| Timer I/O control register L_3      | TIORL_3           | R/W | H'00             | H'FFFE4205 | 8              |
| Timer I/O control register H_4      | TIORH_4           | R/W | H'00             | H'FFFE4206 | 8, 16          |
| Timer I/O control register L_4      | TIORL_4           | R/W | H'00             | H'FFFE4207 | 8              |
| Timer interrupt enable register_3   | TIER_3            | R/W | H'00             | H'FFFE4208 | 8, 16          |

### 11.3.1 Timer Control Register (TCR)

The TCR registers are 8-bit readable/writable registers that control the TCNT operation for each channel. The MTU2 has a total of eight TCR registers, one each for channels 0 to 4 and three (TCRU\_5, TCRV\_5, and TCRW\_5) for channel 5. TCR register settings should be conducted only when TCNT operation is stopped.

|                |           |     |     |           |     |           |     |     |
|----------------|-----------|-----|-----|-----------|-----|-----------|-----|-----|
| Bit:           | 7         | 6   | 5   | 4         | 3   | 2         | 1   | 0   |
|                | CCLR[2:0] |     |     | CKEG[1:0] |     | TPSC[2:0] |     |     |
| Initial value: | 0         | 0   | 0   | 0         | 0   | 0         | 0   | 0   |

| Bit    | Bit Name  | Initial Value | R/W | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------|-----------|---------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 5 | CCLR[2:0] | 000           | R/W | Counter Clear 0 to 2<br><br>These bits select the TCNT counter clearing source. See tables 11.4 and 11.5 for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 4, 3   | CKEG[1:0] | 00            | R/W | Clock Edge 0 and 1<br><br>These bits select the input clock edge. When the input clock is counted using both edges, the input clock period is halved (e.g. $MP\phi/4$ both edges = $MP\phi/2$ rising edge). If phase counting mode is used on channels 1 and 2, this setting is ignored and the phase counting mode setting has priority. Internal clock edge selection is valid when the input clock is $MP\phi/4$ or slower. When $MP\phi/1$ or the overflow/underflow of another channel is selected for the input clock, although values can be written, counter operation compiles with the initial value.<br><br>00: Count at rising edge<br>01: Count at falling edge<br>1x: Count at both edges |
| 2 to 0 | TPSC[2:0] | 000           | R/W | Time Prescaler 0 to 2<br><br>These bits select the TCNT counter clock. The clock source can be selected independently for each channel. See tables 11.6 to 11.10 for details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 11.4 CCLR0 to CCLR2 (Channels 0, 3, and 4)**

| Channel | Bit 7<br>CCLR2 | Bit 6<br>CCLR1 | Bit 5<br>CCLR0 | Description                                                                                                              |
|---------|----------------|----------------|----------------|--------------------------------------------------------------------------------------------------------------------------|
| 0, 3, 4 | 0              | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                |                | 1              | TCNT cleared by TGRA compare match/input capture                                                                         |
|         |                |                | 0              | TCNT cleared by TGRB compare match/input capture                                                                         |
|         |                | 1              | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |
|         |                |                | 0              | TCNT clearing disabled                                                                                                   |
|         |                |                | 1              | TCNT cleared by TGRC compare match/input capture* <sup>2</sup>                                                           |
|         | 1              | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                |                | 1              | TCNT cleared by TGRD compare match/input capture* <sup>2</sup>                                                           |
|         |                |                | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |

Notes: 1. Synchronous operation is set by setting the SYNC bit in TSYR to 1.

2. When TGRC or TGRD is used as a buffer register, TCNT is not cleared because the buffer register setting has priority, and compare match/input capture does not occur.

**Table 11.5 CCLR0 to CCLR2 (Channels 1 and 2)**

| Channel | Bit 7<br>Reserved* <sup>2</sup> | Bit 6<br>CCLR1 | Bit 5<br>CCLR0 | Description                                                                                                              |
|---------|---------------------------------|----------------|----------------|--------------------------------------------------------------------------------------------------------------------------|
| 1, 2    | 0                               | 0              | 0              | TCNT clearing disabled                                                                                                   |
|         |                                 |                | 1              | TCNT cleared by TGRA compare match/input capture                                                                         |
|         |                                 | 1              | 0              | TCNT cleared by TGRB compare match/input capture                                                                         |
|         |                                 |                | 1              | TCNT cleared by counter clearing for another channel performing synchronous clearing/synchronous operation* <sup>1</sup> |

Notes: 1. Synchronous operation is selected by setting the SYNC bit in TSYR to 1.

2. Bit 7 is reserved in channels 1 and 2. It is always read as 0 and cannot be modified.

**Table 11.6 TPSC0 to TPSC2 (Channel 0)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 0       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | External clock: counts on TCLKC pin input |
|         |                |                | 1              | External clock: counts on TCLKD pin input |

**Table 11.7 TPSC0 to TPSC2 (Channel 1)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 1       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /256   |
|         |                |                | 1              | Counts on TCNT_2 overflow/underflow       |

Note: This setting is ignored when channel 1 is in phase counting mode.

**Table 11.8 TPSC0 to TPSC2 (Channel 2)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 2       | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |
|         |                | 1              | 0              | External clock: counts on TCLKC pin input |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /1024  |

Note: This setting is ignored when channel 2 is in phase counting mode.

**Table 11.9 TPSC0 to TPSC2 (Channels 3 and 4)**

| Channel | Bit 2<br>TPSC2 | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                               |
|---------|----------------|----------------|----------------|-------------------------------------------|
| 3, 4    | 0              | 0              | 0              | Internal clock: counts on P $\phi$ /1     |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /4     |
|         |                | 1              | 0              | Internal clock: counts on P $\phi$ /16    |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /64    |
|         | 1              | 0              | 0              | Internal clock: counts on P $\phi$ /256   |
|         |                |                | 1              | Internal clock: counts on P $\phi$ /1024  |
|         |                | 1              | 0              | External clock: counts on TCLKA pin input |
|         |                |                | 1              | External clock: counts on TCLKB pin input |

**Table 11.10 TPSC1 and TPSC0 (Channel 5)**

| Channel | Bit 1<br>TPSC1 | Bit 0<br>TPSC0 | Description                            |
|---------|----------------|----------------|----------------------------------------|
| 5       | 0              | 0              | Internal clock: counts on P $\phi$ /1  |
|         |                | 1              | Internal clock: counts on P $\phi$ /4  |
|         | 1              | 0              | Internal clock: counts on P $\phi$ /16 |
|         |                | 1              | Internal clock: counts on P $\phi$ /64 |

Note: Bits 7 to 2 are reserved in channel 5. These bits are always read as 0. The write value should always be 0.

### 11.3.2 Timer Mode Register (TMDR)

The TMDR registers are 8-bit readable/writable registers that are used to set the operating mode of each channel. The MTU2 has five TMDR registers, one each for channels 0 to 4. TMDR register settings should be changed only when TCNT operation is stopped.

|              |              |              |              |                                                                       |
|              | 1            | 0            | 0            | Setting prohibited                                                    |
|              |              |              | 1            | Complementary PWM mode 1 (transmit at crest) <sup>*3</sup>            |
|              |              | 1            | 0            | Complementary PWM mode 2 (transmit at trough) <sup>*3</sup>           |
|              |              |              | 1            | Complementary PWM mode 2 (transmit at crest and trough) <sup>*3</sup> |

[Legend]

X: Don't care

- Notes:
1. PWM mode 2 cannot be set for channels 3 and 4.
  2. Phase counting mode cannot be set for channels 0, 3, and 4.
  3. Reset synchronous PWM mode, complementary PWM mode can only be set for channel 3. When channel 3 is set to reset synchronous PWM mode or complementary PWM mode, the channel 4 settings become ineffective and automatically conform to the channel 3 settings. However, do not set channel 4 to reset synchronous PWM mode or complementary PWM mode. Reset synchronous PWM mode and complementary PWM mode cannot be set for channels 0, 1, and 2.

### 11.3.3 Timer I/O Control Register (TIOR)

The TIOR registers are 8-bit readable/writable registers that control the TGR registers. The MTU2 has a total of eleven TIOR registers, two each for channels 0, 3, and 4, one each for channels 1 and 2, and three (TIORU\_5, TIORV\_5, and TIORW\_5) for channel 5.

TIOR should be set while TMDR is set in normal operation, PWM mode, or phase counting mode.

The initial output specified by TIOR is valid when the counter is stopped (the CST bit in TSTR is cleared to 0). Note also that, in PWM mode 2, the output at the point at which the counter is cleared to 0 is specified.

When TGRC or TGRD is designated for buffer operation, this setting is invalid and the register operates as a buffer register.

[Legend]

X: Don't care

- Notes: 1. After power-on reset, 0 is output until TIOR is set.
2. When the BFB bit in TMDR\_3 is set to 1 and TGRD\_3 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

[Legend]

X: Don't care

Notes: 1. After power-on reset, 0 is output until TIOR is set.

2. When the BFA bit in TMDR\_0 is set to 1 and TGRC\_0 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

X: Don't care

- Notes: 1. After power-on reset, 0 is output until TIOR is set.
2. When the BFA bit in TMDR\_4 is set to 1 and TGRC\_4 is used as a buffer register, this setting is invalid and input capture/output compare is not generated.

### 11.3.4 Timer Compare Match Clear Register (TCNTCMPCLR)

TCNTCMPCLR is an 8-bit readable/writable register that specifies requests to clear TCNTU\_5, TCNTV\_5, and TCNTW\_5. The MTU2 has one TCNTCMPCLR in channel 5.

|                |   |   |   |   |   |              |              |              |

### 11.3.5 Timer Interrupt Enable Register (TIER)

The TIER registers are 8-bit readable/writable registers that control enabling or disabling of interrupt requests for each channel. The MTU2 has seven TIER registers, two for channel 0 and one each for channels 1 to 5.

- TIER\_0, TIER\_1, TIER\_2, TIER\_3, TIER\_4

### 11.3.6 Timer Status Register (TSR)

The TSR registers are 8-bit readable/writable registers that indicate the status of each channel. The MTU2 has seven TSR registers, two for channel 0 and one each for channels 1 to 5.

- TSR\_0, TSR\_1, TSR\_2, TSR\_3, TSR\_4

Notes: 1. Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.  
2. Timing for transfer is set by the IOC bit in the timer I/O control register U\_5/V\_5/W\_5 (TIOU\_5/V\_5/W\_5).

### 11.3.7 Timer Buffer Operation Transfer Mode Register (TBTM)

The TBTM registers are 8-bit readable/writable registers that specify the timing for transferring data from the buffer register to the timer general register in PWM mode. The MTU2 has three TBTM registers, one each for channels 0, 3, and 4.

### 11.3.8 Timer Input Capture Control Register (TICCR)

TICCR is an 8-bit readable/writable register that specifies input capture conditions when TCNT\_1 and TCNT\_2 are cascaded. The MTU2 has one TICCR in channel 1.

### 11.3.9 Timer Synchronous Clear Register S (TSYCRS)

TSYCRS is an 8-bit readable/writable register that specifies conditions for clearing TCNT\_3 and TCNT\_4 in the MTU2S in synchronization with the MTU2. The MTU2S has one TSYCRS in channel 3 but the MTU2 has no TSYCRS.

### 11.3.10 Timer A/D Converter Start Request Control Register (TADCR)

TADCR is a 16-bit readable/writable register that enables or disables A/D converter start requests and specifies whether to link A/D converter start requests with interrupt skipping operation. The MTU2 has one TADCR in channel 4.

| Bit:           | 15      | 14  | 13 | 12 | 11 | 10 | 9 | 8 | 7     | 6     | 5     | 4     | 3      | 2      | 1      | 0      |

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                                   |
|-----|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | ITB4VE   | 0*            | R/W | TCIV_4 Interrupt Skipping Link Enable<br>Select whether to link A/D converter start requests (TRG4BN) with TCIV_4 interrupt skipping operation.<br>0: Does not link with TCIV_4 interrupt skipping<br>1: Links with TCIV_4 interrupt skipping |

- Notes:
1. TADCR must not be accessed in eight bits; it should always be accessed in 16 bits.
  2. When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), do not link A/D converter start requests with interrupt skipping operation (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).
  3. If link with interrupt skipping is enabled while interrupt skipping is disabled, A/D converter start requests will not be issued.
- \* Do not set to 1 when complementary PWM mode is not selected.

**Table 11.29 Setting of Transfer Timing by Bits BF1 and BF0**

| Bit 7 | Bit 6 |                                                                                                                                        |
|-------|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| BF1   | BF0   | Description                                                                                                                            |
| 0     | 0     | Does not transfer data from the cycle set buffer register to the cycle set register.                                                   |
| 0     | 1     | Transfers data from the cycle set buffer register to the cycle set register at the crest of the TCNT_4 count.* <sup>1</sup>            |
| 1     | 0     | Transfers data from the cycle set buffer register to the cycle set register at the trough of the TCNT_4 count.* <sup>2</sup>           |
| 1     | 1     | Transfers data from the cycle set buffer register to the cycle set register at the crest and trough of the TCNT_4 count.* <sup>2</sup> |

- Notes:
1. Data is transferred from the cycle set buffer register to the cycle set register when the crest of the TCNT\_4 count is reached in complementary PWM mode, when compare match occurs between TCNT\_3 and TGRA\_3 in reset-synchronized PWM mode, or when compare match occurs between TCNT\_4 and TGRA\_4 in PWM mode 1 or normal operation mode.
  2. These settings are prohibited when complementary PWM mode is not selected.

### 11.3.11 Timer A/D Converter Start Request Cycle Set Registers (TADCORA\_4 and TADCORB\_4)

TADCORA\_4 and TADCORB\_4 are 16-bit readable/writable registers. When the TCNT\_4 count reaches the value in TADCORA\_4 or TADCORB\_4, a corresponding A/D converter start request will be issued.

TADCORA\_4 and TADCORB\_4 are initialized to H'FFFF.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: TADCORA\_4 and TADCORB\_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

### 11.3.12 Timer A/D Converter Start Request Cycle Set Buffer Registers (TADCOBRA\_4 and TADCOBRB\_4)

TADCOBRA\_4 and TADCOBRB\_4 are 16-bit readable/writable registers. When the crest or trough of the TCNT\_4 count is reached, these register values are transferred to TADCORA\_4 and TADCORB\_4, respectively.

TADCOBRA\_4 and TADCOBRB\_4 are initialized to H'FFFF.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: TADCOBRA\_4 and TADCOBRB\_4 must not be accessed in eight bits; they should always be accessed in 16 bits.

### 11.3.13 Timer Counter (TCNT)

The TCNT counters are 16-bit readable/writable counters. The MTU2 has eight TCNT counters, one each for channels 0 to 4 and three (TCNTU\_5, TCNTV\_5, and TCNTW\_5) for channel 5.

The TCNT counters are initialized to H'0000 by a reset.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: The TCNT counters must not be accessed in eight bits; they should always be accessed in 16 bits.

### 11.3.14 Timer General Register (TGR)

The TGR registers are 16-bit readable/writable registers. The MTU2 has 21 TGR registers, six for channel 0, two each for channels 1 and 2, four each for channels 3 and 4, and three for channel 5.

TGRA, TGRB, TGRC, and TGRD function as either output compare or input capture registers. TGRC and TGRD for channels 0, 3, and 4 can also be designated for operation as buffer registers. TGR buffer register combinations are TGRA and TGRC, and TGRB and TGRD.

TGRE\_0 and TGRF\_0 function as compare registers. When the TCNT\_0 count matches the TGRE\_0 value, an A/D converter start request can be issued. TGRF can also be designated for operation as a buffer register. TGR buffer register combination is TGRE and TGRF.

TGRU\_5, TGRV\_5, and TGRW\_5 function as compare match, input capture, or external pulse width measurement registers.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: The TGR registers must not be accessed in eight bits; they should always be accessed in 16 bits.  
TGR registers are initialized to H'FFFF.

### 11.3.15 Timer Start Register (TSTR)

TSTR is an 8-bit readable/writable register that selects operation/stoppage of TCNT for channels 0 to 4.

TSTR\_5 is an 8-bit readable/writable register that selects operation/stoppage of TCNTU\_5, TCNTV\_5, and TCNTW\_5 for channel 5.

When setting the operating mode in TMDR or setting the count clock in TCR, first stop the TCNT counter.

- TSTR

### 11.3.16 Timer Synchronous Register (TSYR)

TSYR is an 8-bit readable/writable register that selects independent operation or synchronous operation for the channel 0 to 4 TCNT counters. A channel performs synchronous operation when the corresponding bit in TSYR is set to 1.

### 11.3.17 Timer Counter Synchronous Start Register (TCSYSTR)

TCSYSTR is an 8-bit readable/writable register that specifies synchronous start of the MTU2 and MTU2S counters. Note that the MTU2S does not have TCSYSTR.

Note: Only 1 can be written to set the register.

### 11.3.18 Timer Read/Write Enable Register (TRWER)

TRWER is an 8-bit readable/writable register that enables or disables access to the registers and counters which have write-protection capability against accidental modification in channels 3 and 4.

- Registers and counters having write-protection capability against accidental modification  
22 registers: TCR\_3, TCR\_4, TMDR\_3, TMDR\_4, TIORH\_3, TIORH\_4, TIORL\_3, TIORL\_4, TIER\_3, TIER\_4, TGRA\_3, TGRA\_4, TGRB\_3, TGRB\_4, TOER, TOCR1, TOCR2, TGR, TCDR, TDDR, TCNT\_3, and TCNT4.

### 11.3.19 Timer Output Master Enable Register (TOER)

TOER is an 8-bit readable/writable register that enables/disables output settings for output pins TIOC4D, TIOC4C, TIOC3D, TIOC4B, TIOC4A, and TIOC3B. These pins do not output correctly if the TOER bits have not been set. Set TOER of CH3 and CH4 prior to setting TIOR of CH3 and CH4.

| Bit | Bit Name | Initial Value | R/W | Description                                                                                                                                                    |
|-----|----------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0   | OE3B     | 0             | R/W | Master Enable TIOC3B<br><br>This bit enables/disables the TIOC3B pin MTU2 output.<br>0: MTU2 output is disabled (inactive level)*<br>1: MTU2 output is enabled |

Note: \* The inactive level is determined by the settings in timer output control registers 1 and 2 (TOCR1 and TOCR2). For details, refer to section 11.3.20, Timer Output Control Register 1 (TOCR1), and section 11.3.21, Timer Output Control Register 2 (TOCR2). Set these bits to 1 to enable MTU2 output in other than complementary PWM or reset-synchronized PWM mode. When these bits are set to 0, low level is output.

### 11.3.20 Timer Output Control Register 1 (TOCR1)

TOCR1 is an 8-bit readable/writable register that enables/disables PWM synchronized toggle output in complementary PWM mode/reset synchronized PWM mode, and controls output level inversion of PWM output.

|                |   |      |   |   |        |      |      |      |
|----------------|---|------|---|---|--------|------|------|------|
| Bit:           | 7 | 6    | 5 | 4 | 3      | 2    | 1    | 0    |
|                | - | PSYE | - | - | TOCL   | TOCS | OLSN | OLSP |
| Initial value: | 0 | 0    | 0 | 0 | 0      | 0    | 0    | 0    |
| R/W:           | R | R/W  | R | R | R/(W)* | R/W  | R/W  | R/W  |

Note: \* This bit can be set to 1 only once after a power-on reset. After 1 is written, 0 cannot be written to the bit.

| Bit  | Bit Name | Initial value | R/W | Description                                                                                                                                                                                |
|------|----------|---------------|-----|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7    | —        | 0             | R   | Reserved<br><br>This bit is always read as 0. The write value should always be 0.                                                                                                          |
| 6    | PSYE     | 0             | R/W | PWM Synchronous Output Enable<br><br>This bit selects the enable/disable of toggle output synchronized with the PWM period.<br>0: Toggle output is disabled<br>1: Toggle output is enabled |

| Bit | Bit Name | Initial value | R/W    | Description                                                                                                                                                                                                                                                                                    |
|-----|----------|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3   | TOCL     | 0             | R/(W)* | <p>TOC Register Write Protection*<sup>1</sup></p> <p>This bit selects the enable/disable of write access to the TOCS, OLSN, and OLSP bits in TOCR1.</p> <p>0: Write access to the TOCS, OLSN, and OLSP bits is enabled</p> <p>1: Write access to the TOCS, OLSN, and OLSP bits is disabled</p> |
| 2   | TOCS     | 0             | R/W    | <p>TOC Select</p> <p>This bit selects either the TOCR1 or TOCR2 setting to be used for the output level in complementary PWM mode and reset-synchronized PWM mode.</p> <p>0: TOCR1 setting is selected</p> <p>1: TOCR2 setting is selected</p>                                                 |
| 1   | OLSN     | 0             | R/W    | <p>Output Level Select N*<sup>2</sup>*<sup>3</sup></p> <p>This bit selects the reverse phase output level in reset-synchronized PWM mode/complementary PWM mode. See table 11.30.</p>                                                                                                          |
| 0   | OLSP     | 0             | R/W    | <p>Output Level Select P*<sup>2</sup>*<sup>3</sup></p> <p>This bit selects the positive phase output level in reset-synchronized PWM mode/complementary PWM mode. See table 11.31.</p>                                                                                                         |

- Notes:
1. Setting the TOCL bit to 1 prevents accidental modification when the CPU goes out of control.
  2. Clearing the TOCS0 bit to 0 makes this bit setting valid.
  3. The inverse-phase output is the exact inverse of the positive-phase output unless dead time is generated. When no dead time is generated, only the OLSP setting is valid.

**Table 11.30 Output Level Select Function**

| Bit 1 |                | Function             |            |            |
|-------|----------------|----------------------|------------|------------|
|       |                | Compare Match Output |            |            |
| OLSN  | Initial Output | Active Level         | Up Count   | Down Count |
| 0     | High level     | Low level            | High level | Low level  |
| 1     | Low level      | High level           | Low level  | High level |

Note: The reverse phase waveform initial output value changes to active level after elapse of the dead time after count start.

**Table 11.31 Output Level Select Function**

| Bit 0 | Function       |              |                      |            |
|-------|----------------|--------------|----------------------|------------|
|       | Initial Output | Active Level | Compare Match Output |            |
| OLSP  |                |              | Up Count             | Down Count |
| 0     | High level     | Low level    | Low level            | High level |
| 1     | Low level      | High level   | High level           | Low level  |

Figure 11.2 shows an example of complementary PWM mode output (1 phase) when OLSN = 1, OLSP = 1.

**Figure 11.2 Complementary PWM Mode Output Level Example**

### 11.3.21 Timer Output Control Register 2 (TOCR2)

TOCR2 is an 8-bit readable/writable register that controls output level inversion of PWM output in complementary PWM mode and reset-synchronized PWM mode.

|                |         |     |       |       |       |       |       |       |

**11.3.22 Timer Output Level Buffer Register (TOLBR)**

TOLBR is an 8-bit readable/writable register that functions as a buffer for TOCR2 and specifies the PWM output level in complementary PWM mode and reset-synchronized PWM mode.

|                |   |   |       |       |       |       |       |       |
|----------------|---|---|-------|-------|-------|-------|-------|-------|
| Bit:           | 7 | 6 | 5     | 4     | 3     | 2     | 1     | 0     |
|                | - | - | OLS3N | OLS3P | OLS2N | OLS2P | OLS1N | OLS1P |
| Initial value: | 0 | 0 | 0     | 0     | 0     | 0     | 0     | 0     |
| R/W:           | R | R | R/W   | R/W   | R/W   | R/W   | R/W   | R/W   |

| Bit  | Bit Name | Initial value | R/W | Description                                                                      |
|------|----------|---------------|-----|----------------------------------------------------------------------------------|
| 7, 6 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0. |
| 5    | OLS3N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS3N bit in TOCR2.          |
| 4    | OLS3P    | 0             | R/W | Specifies the buffer value to be transferred to the OLS3P bit in TOCR2.          |
| 3    | OLS2N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS2N bit in TOCR2.          |
| 2    | OLS2P    | 0             | R/W | Specifies the buffer value to be transferred to the OLS2P bit in TOCR2.          |
| 1    | OLS1N    | 0             | R/W | Specifies the buffer value to be transferred to the OLS1N bit in TOCR2.          |
| 0    | OLS1P    | 0             | R/W | Specifies the buffer value to be transferred to the OLS1P bit in TOCR2.          |

Figure 11.3 shows an example of the PWM output level setting procedure in buffer operation.

**Figure 11.3 PWM Output Level Setting Procedure in Buffer Operation**

### 11.3.23 Timer Gate Control Register (TGCR)

TGCR is an 8-bit readable/writable register that controls the waveform output necessary for brushless DC motor control in reset-synchronized PWM mode/complementary PWM mode. These register settings are ineffective for anything other than complementary PWM mode/reset-synchronized PWM mode.

|                |   |     |     |     |     |     |     |     |

|       | 1     | 0     | OFF      | OFF     | ON      | ON      | OFF     | OFF     |
|       |       | 1     | OFF      | OFF     | OFF     | OFF     | OFF     | OFF     |

**11.3.24 Timer Subcounter (TCNTS)**

TCNTS is a 16-bit read-only counter that is used only in complementary PWM mode.

The initial value of TCNTS is H'0000.

|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|----------------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| Initial value: | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| R/W:           | R  | R  | R  | R  | R  | R  | R | R | R | R | R | R | R | R | R | R |

Note: Accessing the TCNTS in 8-bit units is prohibited. Always access in 16-bit units.

### 11.3.25 Timer Dead Time Data Register (TDDR)

TDDR is a 16-bit register, used only in complementary PWM mode that specifies the TCNT\_3 and TCNT\_4 counter offset values. In complementary PWM mode, when the TCNT\_3 and TCNT\_4 counters are cleared and then restarted, the TDDR register value is loaded into the TCNT\_3 counter and the count operation starts.

The initial value of TDDR is H'FFFF.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: Accessing the TDDR in 8-bit units is prohibited. Always access in 16-bit units.

### 11.3.26 Timer Cycle Data Register (TCDR)

TCDR is a 16-bit register used only in complementary PWM mode. Set half the PWM carrier sync value (note that this value should be at least double the value specified in TDDR + 3) as the TCDR register value. This register is constantly compared with the TCNTS counter in complementary PWM mode, and when a match occurs, the TCNTS counter switches direction (decrement to increment).

The initial value of TCDR is H'FFFF.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: Accessing the TCDR in 8-bit units is prohibited. Always access in 16-bit units.

### 11.3.27 Timer Cycle Buffer Register (TCBR)

TCBR is a 16-bit register used only in complementary PWM mode. It functions as a buffer register for the TCDR register. The TCB register values are transferred to the TCDR register with the transfer timing set in the TMDR register.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

Note: Accessing the TCB in 8-bit units is prohibited. Always access in 16-bit units.

### 11.3.28 Timer Interrupt Skipping Set Register (TITCR)

TITCR is an 8-bit readable/writable register that enables or disables interrupt skipping and specifies the interrupt skipping count. The MTU2 has one TITCR.

|                |       |            |     |     |       |            |     |     |
|----------------|-------|------------|-----|-----|-------|------------|-----|-----|
| Bit:           | 7     | 6          | 5   | 4   | 3     | 2          | 1   | 0   |
|                | T3AEN | 3ACOR[2:0] |     |     | T4VEN | 4VCOR[2:0] |     |     |
| Initial value: | 0     | 0          | 0   | 0   | 0     | 0          | 0   | 0   |

| Bit    | Bit Name   | Initial value | R/W | Description                                                                                                                              |
|--------|------------|---------------|-----|------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | T3AEN      | 0             | R/W | T3AEN<br>Enables or disables TGIA_3 interrupt skipping.<br>0: TGIA_3 interrupt skipping disabled<br>1: TGIA_3 interrupt skipping enabled |
| 6 to 4 | 3ACOR[2:0] | 000           | R/W | These bits specify the TGIA_3 interrupt skipping count within the range from 0 to 7.*<br>For details, see table 11.40.                   |
| 3      | T4VEN      | 0             | R/W | T4VEN<br>Enables or disables TCIV_4 interrupt skipping.<br>0: TCIV_4 interrupt skipping disabled<br>1: TCIV_4 interrupt skipping enabled |

| Bit    | Bit Name   | Initial value | R/W | Description                                                                                                                |
|--------|------------|---------------|-----|----------------------------------------------------------------------------------------------------------------------------|
| 2 to 0 | 4VCOR[2:0] | 000           | R/W | These bits specify the TCIV_4 interrupt skipping count within the range from 0 to 7.*<br><br>For details, see table 11.41. |

Note: \* When 0 is specified for the interrupt skipping count, no interrupt skipping will be performed. Before changing the interrupt skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter (TICNT).

**Table 11.40 Setting of Interrupt Skipping Count by Bits 3ACOR2 to 3ACOR0**

| Bit 6  | Bit 5  | Bit 4  |                                                |
|--------|--------|--------|------------------------------------------------|
| 3ACOR2 | 3ACOR1 | 3ACOR0 | Description                                    |
| 0      | 0      | 0      | Does not skip TGIA_3 interrupts.               |
| 0      | 0      | 1      | Sets the TGIA_3 interrupt skipping count to 1. |
| 0      | 1      | 0      | Sets the TGIA_3 interrupt skipping count to 2. |
| 0      | 1      | 1      | Sets the TGIA_3 interrupt skipping count to 3. |
| 1      | 0      | 0      | Sets the TGIA_3 interrupt skipping count to 4. |
| 1      | 0      | 1      | Sets the TGIA_3 interrupt skipping count to 5. |
| 1      | 1      | 0      | Sets the TGIA_3 interrupt skipping count to 6. |
| 1      | 1      | 1      | Sets the TGIA_3 interrupt skipping count to 7. |

**Table 11.41 Setting of Interrupt Skipping Count by Bits 4VCOR2 to 4VCOR0**

| Bit 2  | Bit 1  | Bit 0  |                                                |
|--------|--------|--------|------------------------------------------------|
| 4VCOR2 | 4VCOR1 | 4VCOR0 | Description                                    |
| 0      | 0      | 0      | Does not skip TCIV_4 interrupts.               |
| 0      | 0      | 1      | Sets the TCIV_4 interrupt skipping count to 1. |
| 0      | 1      | 0      | Sets the TCIV_4 interrupt skipping count to 2. |
| 0      | 1      | 1      | Sets the TCIV_4 interrupt skipping count to 3. |
| 1      | 0      | 0      | Sets the TCIV_4 interrupt skipping count to 4. |
| 1      | 0      | 1      | Sets the TCIV_4 interrupt skipping count to 5. |
| 1      | 1      | 0      | Sets the TCIV_4 interrupt skipping count to 6. |
| 1      | 1      | 1      | Sets the TCIV_4 interrupt skipping count to 7. |

### 11.3.29 Timer Interrupt Skipping Counter (TITCNT)

TITCNT is an 8-bit readable/writable counter. The MTU2 has one TITCNT. TITCNT retains its value even after stopping the count operation of TCNT\_3 and TCNT\_4.

|                |   |            |   |   |   |            |   |   |
|----------------|---|------------|---|---|---|------------|---|---|
| Bit:           | 7 | 6          | 5 | 4 | 3 | 2          | 1 | 0 |
|                | - | 3ACNT[2:0] |   |   | - | 4VCNT[2:0] |   |   |
| Initial value: | 0 | 0          | 0 | 0 | 0 | 0          | 0 | 0 |

| 2 to 0 | 4VCNT[2:0] | 000           | R   | TCIV_4 Interrupt Counter<br>While the T4VEN bit in TITCR is set to 1, the count in these bits is incremented every time a TCIV_4 interrupt occurs.<br>[Clearing conditions] <ul style="list-style-type: none"> <li>When the 4VCNT2 to 4VCNT0 value in TITCNT matches the 4VCOR2 to 4VCOR2 value in TITCR</li> <li>When the T4VEN bit in TITCR is cleared to 0</li> <li>When the 4VCOR2 to 4VCOR2 bits in TITCR are cleared to 0</li> </ul> |

**Note:** To clear the TITCNT, clear the bits T3AEN and T4VEN in TITCR to 0.

### 11.3.30 Timer Buffer Transfer Set Register (TBTER)

TBTER is an 8-bit readable/writable register that enables or disables transfer from the buffer registers\* used in complementary PWM mode to the temporary registers and specifies whether to link the transfer with interrupt skipping operation. The MTU2 has one TBTER.

|                |   |   |   |   |   |   |          |     |
|----------------|---|---|---|---|---|---|----------|-----|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1        | 0   |
|                | - | - | - | - | - | - | BTE[1:0] |     |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0        | 0   |
| R/W:           | R | R | R | R | R | R | R/W      | R/W |

| Bit    | Bit Name | Initial Value | R/W | Description                                                                                                                                                                                                                             |
|--------|----------|---------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 2 | —        | All 0         | R   | Reserved<br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                        |
| 1, 0   | BTE[1:0] | 00            | R/W | These bits enable or disable transfer from the buffer registers* used in complementary PWM mode to the temporary registers and specify whether to link the transfer with interrupt skipping operation.<br>For details, see table 11.42. |

Note: \* Applicable buffer registers:  
TGRC\_3, TGRD\_3, TGRC\_4, TGRD\_4, and TCBR

**Table 11.42 Setting of Bits BTE1 and BTE0**

| Bit 1 | Bit 0 |                                                                                                                                                       |
|-------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTE1  | BTE0  | Description                                                                                                                                           |
| 0     | 0     | Enables transfer from the buffer registers to the temporary registers* <sup>1</sup> and does not link the transfer with interrupt skipping operation. |
| 0     | 1     | Disables transfer from the buffer registers to the temporary registers.                                                                               |
| 1     | 0     | Links transfer from the buffer registers to the temporary registers with interrupt skipping operation.* <sup>2</sup>                                  |
| 1     | 1     | Setting prohibited                                                                                                                                    |

- Note:
1. Data is transferred according to the MD3 to MD0 bit setting in TMDR. For details, refer to section 11.4.8, Complementary PWM Mode.
  2. When interrupt skipping is disabled (the T3AEN and T4VEN bits are cleared to 0 in the timer interrupt skipping set register (TITCR) or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0)), be sure to disable link of buffer transfer with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If link with interrupt skipping is enabled while interrupt skipping is disabled, buffer transfer will not be performed.

### 11.3.31 Timer Dead Time Enable Register (TDER)

TDER is an 8-bit readable/writable register that controls dead time generation in complementary PWM mode. The MTU2 has one TDER in channel 3. TDER must be modified only while TCNT stops.

|                |   |   |   |   |   |   |   |       |
|----------------|---|---|---|---|---|---|---|-------|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0     |
|                | - | - | - | - | - | - | - | TDER  |
| Initial value: | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1     |
| R/W:           | R | R | R | R | R | R | R | R/(W) |

| Bit    | Bit Name | Initial Value | R/W   | Description                                                                                                                                                                                                                                                 |
|--------|----------|---------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 to 1 | —        | All 0         | R     | Reserved<br><br>These bits are always read as 0. The write value should always be 0.                                                                                                                                                                        |
| 0      | TDER     | 1             | R/(W) | Dead Time Enable<br><br>Specifies whether to generate dead time.<br>0: Does not generate dead time<br>1: Generates dead time*<br>[Clearing condition]<br><ul style="list-style-type: none"> <li>When 0 is written to TDER after reading TDER = 1</li> </ul> |

Note: \* TDDR must be set to 1 or a larger value.

### 11.3.32 Timer Waveform Control Register (TWCR)

TWCR is an 8-bit readable/writable register that controls the waveform when synchronous counter clearing occurs in TCNT\_3 and TCNT\_4 in complementary PWM mode and specifies whether to clear the counters at TGRA\_3 compare match. The CCE bit and WRE bit in TWCR must be modified only while TCNT stops.

|                |       |   |   |   |   |   |       |       |
|----------------|-------|---|---|---|---|---|-------|-------|
| Bit:           | 7     | 6 | 5 | 4 | 3 | 2 | 1     | 0     |
|                | CCE   | - | - | - | - | - | SCC   | WRE   |
| Initial value: | 0*    | 0 | 0 | 0 | 0 | 0 | 0     | 0     |
| R/W:           | R/(W) | R | R | R | R | R | R/(W) | R/(W) |

Note: \* Do not set to 1 when complementary PWM mode is not selected.

| Bit    | Bit Name | Initial Value | R/W   | Description                                                                                                                                                                                                                                                                                         |

### 11.3.33 Bus Master Interface

The timer counters (TCNT), general registers (TGR), timer subcounter (TCNTS), timer cycle buffer register (TCBR), timer dead time data register (TDDR), timer cycle data register (TCDR), timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCOR), and timer A/D converter start request cycle set buffer registers (TADCOBR) are 16-bit registers. A 16-bit data bus to the bus master enables 16-bit read/writes. 8-bit read/write is not possible. Always access in 16-bit units.

All registers other than the above registers are 8-bit registers. These are connected to the CPU by a 16-bit data bus, so 16-bit read/writes and 8-bit read/writes are both possible.

## 11.4 Operation

### 11.4.1 Basic Functions

Each channel has a TCNT and TGR register. TCNT performs up-counting, and is also capable of free-running operation, cycle counting, and external event counting.

Each TGR can be used as an input capture register or output compare register.

Always select MTU2 external pins set function using the pin function controller (PFC).

#### (1) Counter Operation

When one of bits CST0 to CST4 in TSTR or bits CSTU5, CSTV5, and CSTW5 in TSTR\_5 is set to 1, the TCNT counter for the corresponding channel begins counting. TCNT can operate as a free-running counter, periodic counter, for example.

#### (a) Example of Count Operation Setting Procedure

Figure 11.4 shows an example of the count operation setting procedure.

**Figure 11.4 Example of Counter Operation Setting Procedure**

### (b) Free-Running Count Operation and Periodic Count Operation:

Immediately after a reset, the MTU2's TCNT counters are all designated as free-running counters. When the relevant bit in TSTR is set to 1 the corresponding TCNT counter starts up-count operation as a free-running counter. When TCNT overflows (from H'FFFF to H'0000), the TCFV bit in TSR is set to 1. If the value of the corresponding TCIEV bit in TIER is 1 at this point, the MTU2 requests an interrupt. After overflow, TCNT starts counting up again from H'0000.

Figure 11.5 illustrates free-running counter operation.

**Figure 11.5 Free-Running Counter Operation**

When compare match is selected as the TCNT clearing source, the TCNT counter for the relevant channel performs periodic count operation. The TGR register for setting the period is designated as an output compare register, and counter clearing by compare match is selected by means of bits CCLR0 to CCLR2 in TCR. After the settings have been made, TCNT starts up-count operation as a periodic counter when the corresponding bit in TSTR is set to 1. When the count value matches the value in TGR, the TGF bit in TSR is set to 1 and TCNT is cleared to H'0000.

If the value of the corresponding TGIE bit in TIER is 1 at this point, the MTU2 requests an interrupt. After a compare match, TCNT starts counting up again from H'0000.

Figure 11.6 illustrates periodic counter operation.

**Figure 11.6 Periodic Counter Operation**

## (2) Waveform Output by Compare Match

The MTU2 can perform 0, 1, or toggle output from the corresponding output pin using compare match.

### (a) Example of Setting Procedure for Waveform Output by Compare Match

Figure 11.7 shows an example of the setting procedure for waveform output by compare match.

**Figure 11.7 Example of Setting Procedure for Waveform Output by Compare Match**

### (b) Examples of Waveform Output Operation:

Figure 11.8 shows an example of 0 output/1 output.

In this example TCNT has been designated as a free-running counter, and settings have been made such that 1 is output by compare match A, and 0 is output by compare match B. When the set level and the pin level coincide, the pin level does not change.

**Figure 11.8 Example of 0 Output/1 Output Operation**

Figure 11.9 shows an example of toggle output.

In this example, TCNT has been designated as a periodic counter (with counter clearing on compare match B), and settings have been made such that the output is toggled by both compare match A and compare match B.

**Figure 11.9 Example of Toggle Output Operation**

### (3) Input Capture Function

The TCNT value can be transferred to TGR on detection of the TIOC pin input edge.

Rising edge, falling edge, or both edges can be selected as the detected edge. For channels 0 and 1, it is also possible to specify another channel's counter input clock or compare match signal as the input capture source.

**Note:** When another channel's counter input clock is used as the input capture input for channels 0 and 1,  $P\phi/1$  should not be selected as the counter input clock used for input capture input. Input capture will not be generated if  $P\phi/1$  is selected.

#### (a) Example of Input Capture Operation Setting Procedure

Figure 11.10 shows an example of the input capture operation setting procedure.

**Figure 11.10 Example of Input Capture Operation Setting Procedure**

## (b) Example of Input Capture Operation

Figure 11.11 shows an example of input capture operation.

In this example both rising and falling edges have been selected as the TIOCA pin input capture input edge, the falling edge has been selected as the TIOCB pin input capture input edge, and counter clearing by TGRB input capture has been designated for TCNT.

**Figure 11.11 Example of Input Capture Operation**

## 11.4.2 Synchronous Operation

In synchronous operation, the values in a number of TCNT counters can be rewritten simultaneously (synchronous presetting). Also, a number of TCNT counters can be cleared simultaneously by making the appropriate setting in TCR (synchronous clearing).

Synchronous operation enables TGR to be incremented with respect to a single time base.

Channels 0 to 4 can all be designated for synchronous operation. Channel 5 cannot be used for synchronous operation.

### (1) Example of Synchronous Operation Setting Procedure

Figure 11.12 shows an example of the synchronous operation setting procedure.

**Figure 11.12 Example of Synchronous Operation Setting Procedure**

## (2) Example of Synchronous Operation

Figure 11.13 shows an example of synchronous operation.

In this example, synchronous operation and PWM mode 1 have been designated for channels 0 to 2, TGRB\_0 compare match has been set as the channel 0 counter clearing source, and synchronous clearing has been set for the channel 1 and 2 counter clearing source.

Three-phase PWM waveforms are output from pins TIOC0A, TIOC1A, and TIOC2A. At this time, synchronous presetting, and synchronous clearing by TGRB\_0 compare match, are performed for channel 0 to 2 TCNT counters, and the data set in TGRB\_0 is used as the PWM cycle.

For details of PWM modes, see section 11.4.5, PWM Modes.

**Figure 11.13 Example of Synchronous Operation**

### 11.4.3 Buffer Operation

Buffer operation, provided for channels 0, 3, and 4 enables TGRC and TGRD to be used as buffer registers. In channel 0, TGRF can also be used as a buffer register.

Buffer operation differs depending on whether TGR has been designated as an input capture register or as a compare match register.

Note: TGRE\_0 cannot be designated as an input capture register and can only operate as a compare match register.

Table 11.43 shows the register combinations used in buffer operation.

**Table 11.43 Register Combinations in Buffer Operation**

| Channel | Timer General Register | Buffer Register |
|---------|------------------------|-----------------|
| 0       | TGRA_0                 | TGRC_0          |
|         | TGRB_0                 | TGRD_0          |
|         | TGRE_0                 | TGRF_0          |
| 3       | TGRA_3                 | TGRC_3          |
|         | TGRB_3                 | TGRD_3          |
| 4       | TGRA_4                 | TGRC_4          |
|         | TGRB_4                 | TGRD_4          |

- When TGR is an output compare register

When a compare match occurs, the value in the buffer register for the corresponding channel is transferred to the timer general register.

This operation is illustrated in figure 11.14.

**Figure 11.14 Compare Match Buffer Operation**

- When TGR is an input capture register

When input capture occurs, the value in TCNT is transferred to TGR and the value previously held in the timer general register is transferred to the buffer register.

This operation is illustrated in figure 11.15.

**Figure 11.15 Input Capture Buffer Operation**

### (1) Example of Buffer Operation Setting Procedure

Figure 11.16 shows an example of the buffer operation setting procedure.

**Figure 11.16 Example of Buffer Operation Setting Procedure**

## (2) Examples of Buffer Operation

### (a) When TGR is an output compare register

Figure 11.17 shows an operation example in which PWM mode 1 has been designated for channel 0, and buffer operation has been designated for TGRA and TGRC. The settings used in this example are TCNT clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. In this example, the TTSA bit in TBTM is cleared to 0.

As buffer operation has been set, when compare match A occurs the output changes and the value in buffer register TGRC is simultaneously transferred to timer general register TGRA. This operation is repeated each time that compare match A occurs.

For details of PWM modes, see section 11.4.5, PWM Modes.

**Figure 11.17 Example of Buffer Operation (1)**

### (b) When TGR is an input capture register

Figure 11.18 shows an operation example in which TGRA has been designated as an input capture register, and buffer operation has been designated for TGRA and TGRC.

Counter clearing by TGRA input capture has been set for TCNT, and both rising and falling edges have been selected as the TIOCA pin input capture input edge.

As buffer operation has been set, when the TCNT value is stored in TGRA upon the occurrence of input capture A, the value previously stored in TGRA is simultaneously transferred to TGRC.

**Figure 11.18 Example of Buffer Operation (2)**

### (3) Selecting Timing for Transfer from Buffer Registers to Timer General Registers in Buffer Operation

The timing for transfer from buffer registers to timer general registers can be selected in PWM mode 1 or 2 for channel 0 or in PWM mode 1 for channels 3 and 4 by setting the buffer operation transfer mode registers (TBTM\_0, TBTM\_3, and TBTM\_4). Either compare match (initial setting) or TCNT clearing can be selected for the transfer timing. TCNT clearing as transfer timing is one of the following cases.

- When TCNT overflows (H'FFFF to H'0000)
- When H'0000 is written to TCNT during counting
- When TCNT is cleared to H'0000 under the condition specified in the CCLR2 to CCLR0 bits in TCR

Note: TBTM must be modified only while TCNT stops.

Figure 11.19 shows an operation example in which PWM mode 1 is designated for channel 0 and buffer operation is designated for TGRA\_0 and TGRC\_0. The settings used in this example are TCNT\_0 clearing by compare match B, 1 output at compare match A, and 0 output at compare match B. The TTSA bit in TBTM\_0 is set to 1.

**Figure 11.19 Example of Buffer Operation When TCNT\_0 Clearing is Selected for TGRC\_0 to TGRA\_0 Transfer Timing**

#### 11.4.4 Cascaded Operation

In cascaded operation, two 16-bit counters for different channels are used together as a 32-bit counter.

This function works by counting the channel 1 counter clock upon overflow/underflow of TCNT\_2 as set in bits TPSC0 to TPSC2 in TCR.

Underflow occurs only when the lower 16-bit TCNT is in phase counting mode.

Table 11.44 shows the register combinations used in cascaded operation.

**Note:** When phase counting mode is set for channel 1, the counter clock setting is invalid and the counters operate independently in phase counting mode.

**Table 11.44 Cascaded Combinations**

| Combination      | Upper 16 Bits | Lower 16 Bits |
|------------------|---------------|---------------|
| Channels 1 and 2 | TCNT_1        | TCNT_2        |

For simultaneous input capture of TCNT\_1 and TCNT\_2 during cascaded operation, additional input capture input pins can be specified by the input capture control register (TICCR). Edge detection as the condition for input capture is the detection of edges in the signal produced by taking the logical OR of the signals on the main and additional pins. For details, refer to (4),

Cascaded Operation Example (c). For input capture in cascade connection, refer to section 11.7.22, Simultaneous Capture of TCNT\_1 and TCNT\_2 in Cascade Connection.

Table 11.45 show the TICCRR setting and input capture input pins.

**Table 11.45 TICCRR Setting and Input Capture Input Pins**

| Target Input Capture                | TICCRR Setting               | Input Capture Input Pins |
|-------------------------------------|------------------------------|--------------------------|
| Input capture from TCNT_1 to TGRA_1 | I2AE bit = 0 (initial value) | TIOC1A                   |
|                                     | I2AE bit = 1                 | TIOC1A, TIOC2A           |
| Input capture from TCNT_1 to TGRB_1 | I2BE bit = 0 (initial value) | TIOC1B                   |
|                                     | I2BE bit = 1                 | TIOC1B, TIOC2B           |
| Input capture from TCNT_2 to TGRA_2 | I1AE bit = 0 (initial value) | TIOC2A                   |
|                                     | I1AE bit = 1                 | TIOC2A, TIOC1A           |
| Input capture from TCNT_2 to TGRB_2 | I1BE bit = 0 (initial value) | TIOC2B                   |
|                                     | I1BE bit = 1                 | TIOC2B, TIOC1B           |

### (1) Example of Cascaded Operation Setting Procedure

Figure 11.20 shows an example of the setting procedure for cascaded operation.

**Figure 11.20 Cascaded Operation Setting Procedure**

### (2) Cascaded Operation Example (a)

Figure 11.21 illustrates the operation when TCNT\_2 overflow/underflow counting has been set for TCNT\_1 and phase counting mode has been designated for channel 2.

TCNT\_1 is incremented by TCNT\_2 overflow and decremented by TCNT\_2 underflow.

**Figure 11.21 Cascaded Operation Example (a)**

### (3) Cascaded Operation Example (b)

Figure 11.22 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE bit in TICC\_R has been set to 1 to include the TIOC2A pin in the TGRA\_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR\_1 have selected the TIOC1A rising edge for the input capture timing while the IOA0 to IOA3 bits in TIOR\_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, the rising edge of both TIOC1A and TIOC2A is used for the TGRA\_1 input capture condition. For the TGRA\_2 input capture condition, the TIOC2A rising edge is used.

**Figure 11.22 Cascaded Operation Example (b)**

#### (4) Cascaded Operation Example (c)

Figure 11.23 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE and I1AE bits in TICCRR have been set to 1 to include the TIOC2A and TIOC1A pins in the TGRA\_1 and TGRA\_2 input capture conditions, respectively. In this example, the IOA0 to IOA3 bits in both TIOR\_1 and TIOR\_2 have selected both the rising and falling edges for the input capture timing. Under these conditions, the ORed result of TIOC1A and TIOC2A input is used for the TGRA\_1 and TGRA\_2 input capture conditions.

**Figure 11.23 Cascaded Operation Example (c)**

### (5) Cascaded Operation Example (d)

Figure 11.24 illustrates the operation when TCNT\_1 and TCNT\_2 have been cascaded and the I2AE bit in TICC\_R has been set to 1 to include the TIOC2A pin in the TGRA\_1 input capture conditions. In this example, the IOA0 to IOA3 bits in TIOR\_1 have selected TGRA\_0 compare match or input capture occurrence for the input capture timing while the IOA0 to IOA3 bits in TIOR\_2 have selected the TIOC2A rising edge for the input capture timing.

Under these conditions, as TIOR\_1 has selected TGRA\_0 compare match or input capture occurrence for the input capture timing, the TIOC2A edge is not used for TGRA\_1 input capture condition although the I2AE bit in TICC\_R has been set to 1.

**Figure 11.24 Cascaded Operation Example (d)**

### 11.4.5 PWM Modes

In PWM mode, PWM waveforms are output from the output pins. The output level can be selected as 0, 1, or toggle output in response to a compare match of each TGR.

TGR registers settings can be used to output a PWM waveform in the range of 0% to 100% duty.

Designating TGR compare match as the counter clearing source enables the period to be set in that register. All channels can be designated for PWM mode independently. Synchronous operation is also possible.

There are two PWM modes, as described below.

- PWM mode 1

PWM output is generated from the TIOCA and TIOCC pins by pairing TGRA with TGRB and TGRC with TGRD. The output specified by bits IOA0 to IOA3 and IOC0 to IOC3 in TIOR is output from the TIOCA and TIOCC pins at compare matches A and C, and the output specified by bits IOB0 to IOB3 and IOD0 to IOD3 in TIOR is output at compare matches B and D. The initial output value is the value set in TGRA or TGRC. If the set values of paired TGRs are identical, the output value does not change when a compare match occurs.

In PWM mode 1, a maximum 8-phase PWM output is possible.

- PWM mode 2

PWM output is generated using one TGR as the cycle register and the others as duty registers. The output specified in TIOR is performed by means of compare matches. Upon counter clearing by the cycle register compare match, the output value of each pin is the initial value set in TIOR. If the set values of the cycle and duty registers are identical, the output value does not change when a compare match occurs.

In PWM mode 2, a maximum 8-phase PWM output is possible in combination use with synchronous operation.

The correspondence between PWM output pins and registers is shown in table 11.46.

**Table 11.46 PWM Output Registers and Output Pins**

| Channel | Registers | Output Pins |               |
|---------|-----------|-------------|---------------|
|         |           | PWM Mode 1  | PWM Mode 2    |
| 0       | TGRA_0    | TIOC0A      | TIOC0A        |
|         | TGRB_0    |             | TIOC0B        |
|         | TGRC_0    | TIOC0C      | TIOC0C        |
|         | TGRD_0    |             | TIOC0D        |
| 1       | TGRA_1    | TIOC1A      | TIOC1A        |
|         | TGRB_1    |             | TIOC1B        |
| 2       | TGRA_2    | TIOC2A      | TIOC2A        |
|         | TGRB_2    |             | TIOC2B        |
| 3       | TGRA_3    | TIOC3A      | Cannot be set |
|         | TGRB_3    |             | Cannot be set |
|         | TGRC_3    | TIOC3C      | Cannot be set |
|         | TGRD_3    |             | Cannot be set |
| 4       | TGRA_4    | TIOC4A      | Cannot be set |
|         | TGRB_4    |             | Cannot be set |
|         | TGRC_4    | TIOC4C      | Cannot be set |
|         | TGRD_4    |             | Cannot be set |

Note: In PWM mode 2, PWM output is not possible for the TGR register in which the period is set.

## (1) Example of PWM Mode Setting Procedure

Figure 11.25 shows an example of the PWM mode setting procedure.

**Figure 11.25 Example of PWM Mode Setting Procedure**

## (2) Examples of PWM Mode Operation

Figure 11.26 shows an example of PWM mode 1 operation.

In this example, TGRA compare match is set as the TCNT clearing source, 0 is set for the TGRA initial output value and output value, and 1 is set as the TGRB output value.

In this case, the value set in TGRA is used as the period, and the values set in the TGRB registers are used as the duty levels.

**Figure 11.26 Example of PWM Mode Operation (1)**

Figure 11.27 shows an example of PWM mode 2 operation.

In this example, synchronous operation is designated for channels 0 and 1, TGRB\_1 compare match is set as the TCNT clearing source, and 0 is set for the initial output value and 1 for the output value of the other TGR registers (TGRA\_0 to TGRD\_0, TGRA\_1), outputting a 5-phase PWM waveform.

In this case, the value set in TGRB\_1 is used as the cycle, and the values set in the other TGRs are used as the duty levels.

**Figure 11.27 Example of PWM Mode Operation (2)**

Figure 11.28 shows examples of PWM waveform output with 0% duty and 100% duty in PWM mode.

**Figure 11.28 Example of PWM Mode Operation (3)**

### 11.4.6 Phase Counting Mode

In phase counting mode, the phase difference between two external clock inputs is detected and TCNT is incremented/decremented accordingly. This mode can be set for channels 1 and 2.

When phase counting mode is set, an external clock is selected as the counter input clock and TCNT operates as an up/down-counter regardless of the setting of bits TPSC0 to TPSC2 and bits CKEG0 and CKEG1 in TCR. However, the functions of bits CCLR0 and CCLR1 in TCR, and of TIOR, TIER, and TGR, are valid, and input capture/compare match and interrupt functions can be used.

This can be used for two-phase encoder pulse input.

If overflow occurs when TCNT is counting up, the TCFV flag in TSR is set; if underflow occurs when TCNT is counting down, the TCFU flag is set.

The TCFD bit in TSR is the count direction flag. Reading the TCFD flag reveals whether TCNT is counting up or down.

Table 11.47 shows the correspondence between external clock pins and channels.

**Table 11.47 Phase Counting Mode Clock Input Pins**

| Channels                                     | External Clock Pins |         |
|----------------------------------------------|---------------------|---------|
|                                              | A-Phase             | B-Phase |
| When channel 1 is set to phase counting mode | TCLKA               | TCLKB   |
| When channel 2 is set to phase counting mode | TCLKC               | TCLKD   |

#### (1) Example of Phase Counting Mode Setting Procedure

Figure 11.29 shows an example of the phase counting mode setting procedure.

**Figure 11.29 Example of Phase Counting Mode Setting Procedure**

(2) Examples of Phase Counting Mode Operation

In phase counting mode, TCNT counts up or down according to the phase difference between two external clocks. There are four modes according to the count conditions.

(a) Phase counting mode 1

Figure 11.30 shows an example of phase counting mode 1 operation, and table 11.48 summarizes the TCNT up/down-count conditions.

Figure 11.30 Example of Phase Counting Mode 1 Operation

Table 11.48 Up/Down-Count Conditions in Phase Counting Mode 1

| TCLKA (Channel 1)<br>TCLKC (Channel 2) | TCLKB (Channel 1)<br>TCLKD (Channel 2) | Operation  |
|----------------------------------------|----------------------------------------|------------|
| High level                             |                                        | Up-count   |
| Low level                              |                                        |            |
|                                        | Low level                              |            |
|                                        | High level                             |            |
| High level                             |                                        | Down-count |
| Low level                              |                                        |            |
|                                        | High level                             |            |
|                                        | Low level                              |            |

### (3) Phase Counting Mode Application Example

Figure 11.34 shows an example in which channel 1 is in phase counting mode, and channel 1 is coupled with channel 0 to input servo motor 2-phase encoder pulses in order to detect position or speed.

Channel 1 is set to phase counting mode 1, and the encoder pulse A-phase and B-phase are input to TCLKA and TCLKB.

Channel 0 operates with TCNT counter clearing by TGRC\_0 compare match; TGRA\_0 and TGRC\_0 are used for the compare match function and are set with the speed control period and position control period. TGRB\_0 is used for input capture, with TGRB\_0 and TGRD\_0 operating in buffer mode. The channel 1 counter input clock is designated as the TGRB\_0 input capture source, and the pulse widths of 2-phase encoder 4-multiplication pulses are detected.

TGRA\_1 and TGRB\_1 for channel 1 are designated for input capture, and channel 0 TGRA\_0 and TGRC\_0 compare matches are selected as the input capture source and store the up/down-counter values for the control periods.

This procedure enables the accurate detection of position and speed.

**Figure 11.34 Phase Counting Mode Application Example**

### 11.4.7 Reset-Synchronized PWM Mode

In reset-synchronized PWM mode, three-phase output of positive and negative PWM waveforms that share a common wave transition point can be obtained by combining channels 3 and 4.

When set for reset-synchronized PWM mode, the TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, and TIOC4D pins function as PWM output pins and TCNT3 functions as an upcounter.

Table 11.52 shows the PWM output pins used. Table 11.53 shows the settings of the registers.

**Table 11.52 Output Pins for Reset-Synchronized PWM Mode**

| Channel | Output Pin | Description                                                 |
|---------|------------|-------------------------------------------------------------|
| 3       | TIOC3B     | PWM output pin 1                                            |
|         | TIOC3D     | PWM output pin 1' (negative-phase waveform of PWM output 1) |
| 4       | TIOC4A     | PWM output pin 2                                            |
|         | TIOC4C     | PWM output pin 2' (negative-phase waveform of PWM output 2) |
|         | TIOC4B     | PWM output pin 3                                            |
|         | TIOC4D     | PWM output pin 3' (negative-phase waveform of PWM output 3) |

**Table 11.53 Register Settings for Reset-Synchronized PWM Mode**

| Register | Description of Setting                                                       |
|----------|------------------------------------------------------------------------------|
| TCNT_3   | Initial setting of H'0000                                                    |
| TCNT_4   | Initial setting of H'0000                                                    |
| TGRA_3   | Set count cycle for TCNT_3                                                   |
| TGRB_3   | Sets the turning point for PWM waveform output by the TIOC3B and TIOC3D pins |
| TGRA_4   | Sets the turning point for PWM waveform output by the TIOC4A and TIOC4C pins |
| TGRB_4   | Sets the turning point for PWM waveform output by the TIOC4B and TIOC4D pins |

## (1) Procedure for Selecting the Reset-Synchronized PWM Mode

Figure 11.35 shows an example of procedure for selecting reset-synchronized PWM mode.

**Figure 11.35 Procedure for Selecting Reset-Synchronized PWM Mode**

## (2) Reset-Synchronized PWM Mode Operation

Figure 11.36 shows an example of operation in reset-synchronized PWM mode. TCNT\_3 and TCNT\_4 operate as upcounters. The counter is cleared when a TCNT\_3 and TGRA\_3 compare-match occurs, and then begins incrementing from H'0000. The PWM output pin output toggles with each occurrence of a TGRB\_3, TGRA\_4, TGRB\_4 compare-match, and upon counter clears.

**Figure 11.36 Reset-Synchronized PWM Mode Operation Example**  
(When TOCR's OLSN = 1 and OLSP = 1)

### 11.4.8 Complementary PWM Mode

In complementary PWM mode, three-phase output of non-overlapping positive and negative PWM waveforms can be obtained by combining channels 3 and 4. PWM waveforms without non-overlapping interval are also available.

In complementary PWM mode, TIOC3B, TIOC3D, TIOC4A, TIOC4B, TIOC4C, and TIOC4D pins function as PWM output pins, the TIOC3A pin can be set for toggle output synchronized with the PWM period. TCNT\_3 and TCNT\_4 function as up/down counters.

Table 11.54 shows the PWM output pins used. Table 11.55 shows the settings of the registers used. Figure 11.37 describes a block diagram of channels 3 and 4 in complementary PWM mode.

A function to directly cut off the PWM output by using an external signal is supported as a port function.

**Table 11.54 Output Pins for Complementary PWM Mode**

| Channel | Output Pin | Description                                                                                                                                      |
|---------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 3       | TIOC3A     | Toggle output synchronized with PWM period (or I/O port)                                                                                         |
|         | TIOC3B     | PWM output pin 1                                                                                                                                 |
|         | TIOC3C     | I/O port*                                                                                                                                        |
|         | TIOC3D     | PWM output pin 1'<br>(non-overlapping negative-phase waveform of PWM output 1;<br>PWM output without non-overlapping interval is also available) |
| 4       | TIOC4A     | PWM output pin 2                                                                                                                                 |
|         | TIOC4B     | PWM output pin 3                                                                                                                                 |
|         | TIOC4C     | PWM output pin 2'<br>(non-overlapping negative-phase waveform of PWM output 2;<br>PWM output without non-overlapping interval is also available) |
|         | TIOC4D     | PWM output pin 3'<br>(non-overlapping negative-phase waveform of PWM output 3;<br>PWM output without non-overlapping interval is also available) |

Note: \* Avoid setting the TIOC3C pin as a timer I/O pin in complementary PWM mode.

**Table 11.55 Register Settings for Complementary PWM Mode**

| Channel                              | Counter/Register | Description                                                  | Read/Write from CPU        |
|--------------------------------------|------------------|--------------------------------------------------------------|----------------------------|
| 3                                    | TCNT_3           | Start of up-count from value set in dead time register       | Maskable by TRWER setting* |

Note: \* Access can be enabled or disabled according to the setting of bit 0 (RWE) in TRWER (timer read/write enable register).

**Figure 11.37** Block Diagram of Channels 3 and 4 in Complementary PWM Mode

## (1) Example of Complementary PWM Mode Setting Procedure

An example of the complementary PWM mode setting procedure is shown in figure 11.38.

**Figure 11.38 Example of Complementary PWM Mode Setting Procedure**

## (2) Outline of Complementary PWM Mode Operation

In complementary PWM mode, 6-phase PWM output is possible. Figure 11.39 illustrates counter operation in complementary PWM mode, and figure 11.40 shows an example of complementary PWM mode operation.

### (a) Counter Operation

In complementary PWM mode, three counters—TCNT\_3, TCNT\_4, and TCNTS—perform up/down-count operations.

TCNT\_3 is automatically initialized to the value set in TDDR when complementary PWM mode is selected and the CST bit in TSTR is 0.

When the CST bit is set to 1, TCNT\_3 counts up to the value set in TGRA\_3, then switches to down-counting when it matches TGRA\_3. When the TCNT3 value matches TDDR, the counter switches to up-counting, and the operation is repeated in this way.

TCNT\_4 is initialized to H'0000.

When the CST bit is set to 1, TCNT4 counts up in synchronization with TCNT\_3, and switches to down-counting when it matches TCDR. On reaching H'0000, TCNT4 switches to up-counting, and the operation is repeated in this way.

TCNTS is a read-only counter. It need not be initialized.

When TCNT\_3 matches TCDR during TCNT\_3 and TCNT\_4 up/down-counting, down-counting is started, and when TCNTS matches TCDR, the operation switches to up-counting. When TCNTS matches TGRA\_3, it is cleared to H'0000.

When TCNT\_4 matches TDDR during TCNT\_3 and TCNT\_4 down-counting, up-counting is started, and when TCNTS matches TDDR, the operation switches to down-counting. When TCNTS reaches H'0000, it is set with the value in TGRA\_3.

TCNTS is compared with the compare register and temporary register in which the PWM duty is set during the count operation only.

**Figure 11.39 Complementary PWM Mode Counter Operation**

### (b) Register Operation

In complementary PWM mode, nine registers are used, comprising compare registers, buffer registers, and temporary registers. Figure 11.40 shows an example of complementary PWM mode operation.

The registers which are constantly compared with the counters to perform PWM output are TGRB\_3, TGRA\_4, and TGRB\_4. When these registers match the counter, the value set in bits OLSN and OLSP in the timer output control register (TOCR) is output.

The buffer registers for these compare registers are TGRD\_3, TGRC\_4, and TGRD\_4.

Between a buffer register and compare register there is a temporary register. The temporary registers cannot be accessed by the CPU.

Data in a compare register is changed by writing the new data to the corresponding buffer register. The buffer registers can be read or written at any time.

The data written to a buffer register is constantly transferred to the temporary register in the Ta interval. Data is not transferred to the temporary register in the Tb interval. Data written to a buffer register in this interval is transferred to the temporary register at the end of the Tb interval.

The value transferred to a temporary register is transferred to the compare register when TCNTS for which the Tb interval ends matches TGRA\_3 when counting up, or H'0000 when counting down. The timing for transfer from the temporary register to the compare register can be selected with bits MD3 to MD0 in the timer mode register (TMDR). Figure 11.40 shows an example in which the mode is selected in which the change is made in the trough.

In the Tb interval (tb1 in figure 11.40) in which data transfer to the temporary register is not performed, the temporary register has the same function as the compare register, and is compared with the counter. In this interval, therefore, there are two compare match registers for one-phase output, with the compare register containing the pre-change data, and the temporary register containing the new data. In this interval, the three counters—TCNT\_3, TCNT\_4, and TCNTS—and two registers—compare register and temporary register—are compared, and PWM output controlled accordingly.

**Figure 11.40 Example of Complementary PWM Mode Operation**

### (c) Initialization

In complementary PWM mode, there are six registers that must be initialized. In addition, there is a register that specifies whether to generate dead time (it should be used only when dead time generation should be disabled).

Before setting complementary PWM mode with bits MD3 to MD0 in the timer mode register (TMDR), the following initial register values must be set.

TGRC\_3 operates as the buffer register for TGRA\_3, and should be set with  $1/2$  the PWM carrier cycle + dead time Td. The timer cycle buffer register (TCBR) operates as the buffer register for the timer cycle data register (TCDR), and should be set with  $1/2$  the PWM carrier cycle. Set dead time Td in the timer dead time data register (TDDR).

When dead time is not needed, the TDER bit in the timer dead time enable register (TDER) should be cleared to 0, TGRC\_3 and TGRA\_3 should be set to  $1/2$  the PWM carrier cycle + 1, and TDDR should be set to 1.

Set the respective initial PWM duty values in buffer registers TGRD\_3, TGRC\_4, and TGRD\_4.

The values set in the five buffer registers excluding TDDR are transferred simultaneously to the corresponding compare registers when complementary PWM mode is set.

Set TCNT\_4 to H'0000 before setting complementary PWM mode.

**Table 11.56 Registers and Counters Requiring Initialization**

| Register/Counter       | Set Value                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------|
| TGRC_3                 | $1/2$ PWM carrier cycle + dead time Td<br>( $1/2$ PWM carrier cycle + 1 when dead time generation is disabled by TDER) |
| TDDR                   | Dead time Td (1 when dead time generation is disabled by TDER)                                                         |
| TCBR                   | $1/2$ PWM carrier cycle                                                                                                |
| TGRD_3, TGRC_4, TGRD_4 | Initial PWM duty value for each phase                                                                                  |
| TCNT_4                 | H'0000                                                                                                                 |

**Note:** The TGRC\_3 set value must be the sum of  $1/2$  the PWM carrier cycle set in TCBR and dead time Td set in TDDR. When dead time generation is disabled by TDER, TGRC\_3 must be set to  $1/2$  the PWM carrier cycle + 1.

#### (d) PWM Output Level Setting

In complementary PWM mode, the PWM pulse output level is set with bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1P to OLS3P and OLS1N to OLS3N in timer output control register 2 (TOCR2).

The output level can be set for each of the three positive phases and three negative phases of 6-phase output.

Complementary PWM mode should be cleared before setting or changing output levels.

#### (e) Dead Time Setting

In complementary PWM mode, PWM pulses are output with a non-overlapping relationship between the positive and negative phases. This non-overlap time is called the dead time.

The non-overlap time is set in the timer dead time data register (TDDR). The value set in TDDR is used as the TCNT\_3 counter start value, and creates non-overlap between TCNT\_3 and TCNT\_4. Complementary PWM mode should be cleared before changing the contents of TDDR.

#### (f) Dead Time Suppressing

Dead time generation is suppressed by clearing the TDER bit in the timer dead time enable register (TDER) to 0. TDER can be cleared to 0 only when 0 is written to it after reading TDER = 1.

TGRA\_3 and TGRC\_3 should be set to  $1/2$  PWM carrier cycle + 1 and the timer dead time data register (TDDR) should be set to 1.

By the above settings, PWM waveforms without dead time can be obtained. Figure 11.41 shows an example of operation without dead time.

**Figure 11.41 Example of Operation without Dead Time**

### (g) PWM Cycle Setting

In complementary PWM mode, the PWM pulse cycle is set in two registers—TGRA\_3, in which the TCNT\_3 upper limit value is set, and TCDR, in which the TCNT\_4 upper limit value is set. The settings should be made so as to achieve the following relationship between these two registers:

With dead time: TGRA\_3 set value = TCDR set value + TDDR set value

TCNT\_3 set value > Double the TDDR set value + 2

Without dead time: TGRA\_3 set value = TCDR set value + 1

The TGRA\_3 and TCDR settings are made by setting the values in buffer registers TGRC\_3 and TCBR. The values set in TGRC\_3 and TCBR are transferred simultaneously to TGRA\_3 and TCDR in accordance with the transfer timing selected with bits MD3 to MD0 in the timer mode register (TMDR).

The updated PWM cycle is reflected from the next cycle when the data update is performed at the crest, and from the current cycle when performed in the trough. Figure 11.42 illustrates the operation when the PWM cycle is updated at the crest.

See the following section, Register Data Updating, for the method of updating the data in each buffer register.

**Figure 11.42 Example of PWM Cycle Updating**

## (h) Register Data Updating

In complementary PWM mode, the buffer register is used to update the data in a compare register. The update data can be written to the buffer register at any time. There are five PWM duty and carrier cycle registers that have buffer registers and can be updated during operation.

There is a temporary register between each of these registers and its buffer register. When subcounter TCNTS is not counting, if buffer register data is updated, the temporary register value is also rewritten. Transfer is not performed from buffer registers to temporary registers when TCNTS is counting; in this case, the value written to a buffer register is transferred after TCNTS halts.

The temporary register value is transferred to the compare register at the data update timing set with bits MD3 to MD0 in the timer mode register (TMDR). Figure 11.43 shows an example of data updating in complementary PWM mode. This example shows the mode in which data updating is performed at both the counter crest and trough.

When rewriting buffer register data, a write to TGRD\_4 must be performed at the end of the update. Data transfer from the buffer registers to the temporary registers is performed simultaneously for all five registers after the write to TGRD\_4.

A write to TGRD\_4 must be performed after writing data to the registers to be updated, even when not updating all five registers, or when updating the TGRD\_4 data. In this case, the data written to TGRD\_4 should be the same as the data prior to the write operation.

Figure 11.43 Example of Data Update in Complementary PWM Mode

### (i) Initial Output in Complementary PWM Mode

In complementary PWM mode, the initial output is determined by the setting of bits OLSN and OLSP in timer output control register 1 (TOCR1) or bits OLS1N to OLS3N and OLS1P to OLS3P in timer output control register 2 (TOCR2).

This initial output is the PWM pulse non-active level, and is output from when complementary PWM mode is set with the timer mode register (TMDR) until TCNT\_4 exceeds the value set in the dead time register (TDDR). Figure 11.44 shows an example of the initial output in complementary PWM mode.

An example of the waveform when the initial PWM duty value is smaller than the TDDR value is shown in figure 11.45.

**Figure 11.44 Example of Initial Output in Complementary PWM Mode (1)**

**Timer output control register settings**

OLSN bit: 0 (initial output: high; active level: low)

OLSP bit: 0 (initial output: high; active level: low)

**Figure 11.45 Example of Initial Output in Complementary PWM Mode (2)**

### (j) Complementary PWM Mode PWM Output Generation Method

In complementary PWM mode, 3-phase output is performed of PWM waveforms with a non-overlap time between the positive and negative phases. This non-overlap time is called the dead time.

A PWM waveform is generated by output of the output level selected in the timer output control register in the event of a compare-match between a counter and compare register. While TCNTS is counting, compare register and temporary register values are simultaneously compared to create consecutive PWM pulses from 0 to 100%. The relative timing of on and off compare-match occurrence may vary, but the compare-match that turns off each phase takes precedence to secure the dead time and ensure that the positive phase and negative phase on times do not overlap. Figures 11.46 to 11.48 show examples of waveform generation in complementary PWM mode.

The positive phase/negative phase off timing is generated by a compare-match with the solid-line counter, and the on timing by a compare-match with the dotted-line counter operating with a delay of the dead time behind the solid-line counter. In the T1 period, compare-match **a** that turns off the negative phase has the highest priority, and compare-matches occurring prior to **a** are ignored. In the T2 period, compare-match **c** that turns off the positive phase has the highest priority, and compare-matches occurring prior to **c** are ignored.

In normal cases, compare-matches occur in the order **a** → **b** → **c** → **d** (or **c** → **d** → **a'** → **b'**), as shown in figure 11.46.

If compare-matches deviate from the **a** → **b** → **c** → **d** order, since the time for which the negative phase is off is less than twice the dead time, the figure shows the positive phase is not being turned on. If compare-matches deviate from the **c** → **d** → **a'** → **b'** order, since the time for which the positive phase is off is less than twice the dead time, the figure shows the negative phase is not being turned on.

If compare-match **c** occurs first following compare-match **a**, as shown in figure 11.47, compare-match **b** is ignored, and the negative phase is turned on by compare-match **d**. This is because turning off of the positive phase has priority due to the occurrence of compare-match **c** (positive phase off timing) before compare-match **b** (positive phase on timing) (consequently, the waveform does not change since the positive phase goes from off to off).

Similarly, in the example in figure 11.48, compare-match **a'** with the new data in the temporary register occurs before compare-match **c**, but other compare-matches occurring up to **c**, which turns off the positive phase, are ignored. As a result, the negative phase is not turned on.

Thus, in complementary PWM mode, compare-matches at turn-off timings take precedence, and turn-on timing compare-matches that occur before a turn-off timing compare-match are ignored.

**Figure 11.46 Example of Complementary PWM Mode Waveform Output (1)**

**Figure 11.47 Example of Complementary PWM Mode Waveform Output (2)**

**Figure 11.48 Example of Complementary PWM Mode Waveform Output (3)**

### (k) Complementary PWM Mode 0% and 100% Duty Output

In complementary PWM mode, 0% and 100% duty cycles can be output as required. Figures 11.49 to 11.53 show output examples.

100% duty output is performed when the compare register value is set to H'0000. The waveform in this case has a positive phase with a 100% on-state. 0% duty output is performed when the compare register value is set to the same value as TGRA\_3. The waveform in this case has a positive phase with a 100% off-state.

On and off compare-matches occur simultaneously, but if a turn-on compare-match and turn-off compare-match for the same phase occur simultaneously, both compare-matches are ignored and the waveform does not change.

**Figure 11.49 Example of Complementary PWM Mode 0% and 100% Waveform Output (1)**

**Figure 11.53 Example of Complementary PWM Mode 0% and 100% Waveform Output (5)**

#### (I) Toggle Output Synchronized with PWM Cycle

In complementary PWM mode, toggle output can be performed in synchronization with the PWM carrier cycle by setting the PSYE bit to 1 in the timer output control register (TOCR). An example of a toggle output waveform is shown in figure 11.54.

This output is toggled by a compare-match between TCNT\_3 and TGRA\_3 and a compare-match between TCNT4 and H'0000.

The output pin for this toggle output is the TIOC3A pin. The initial output is 1.

**Figure 11.54 Example of Toggle Output Waveform Synchronized with PWM Output**

### (m) Counter Clearing by Another Channel

In complementary PWM mode, by setting a mode for synchronization with another channel by means of the timer synchronous register (TSYR), and selecting synchronous clearing with bits CCLR2 to CCLR0 in the timer control register (TCR), it is possible to have TCNT\_3, TCNT\_4, and TCNTS cleared by another channel.

Figure 11.55 illustrates the operation.

Use of this function enables counter clearing and restarting to be performed by means of an external signal.

**Figure 11.55 Counter Clearing Synchronized with Another Channel**

## (n) Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

Setting the WRE bit in TWCR to 1 suppresses initial output when synchronous counter clearing occurs in the Tb interval at the trough in complementary PWM mode and controls abrupt change in duty cycle at synchronous counter clearing.

Initial output suppression is applicable only when synchronous clearing occurs in the Tb interval at the trough as indicated by (10) or (11) in figure 11.56. When synchronous clearing occurs outside that interval, the initial value specified by the OLS bits in TOCR is output. Even in the Tb interval at the trough, if synchronous clearing occurs in the initial value output period (indicated by (1) in figure 11.56) immediately after the counters start operation, initial value output is not suppressed.

This function can be used in both the MTU2 and MTU2S. In the MTU2, synchronous clearing generated in channels 0 to 2 in the MTU2 can cause counter clearing in complementary PWM mode; in the MTU2S, compare match or input capture flag setting in channels 0 to 2 in the MTU2 can cause counter clearing.

Figure 11.56 Timing for Synchronous Counter Clearing

- Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

An example of the procedure for setting output waveform control at synchronous counter clearing in complementary PWM mode is shown in figure 11.57.

**Figure 11.57 Example of Procedure for Setting Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode**

- Examples of Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

Figures 11.58 to 11.61 show examples of output waveform control in which the MTU2 operates in complementary PWM mode and synchronous counter clearing is generated while the WRE bit in TWCR is set to 1. In the examples shown in figures 11.58 to 11.61, synchronous counter clearing occurs at timing (3), (6), (8), and (11) shown in figure 11.56, respectively.

In the MTU2S, these examples are equivalent to the cases when the MTU2S operates in complementary PWM mode and synchronous counter clearing is generated while the SCC bit is cleared to 0 and the WRE bit is set to 1 in TWCR.

**Figure 11.58 Example of Synchronous Clearing in Dead Time during Up-Counting**  
(Timing (3) in Figure 11.56; Bit WRE of TWCR in MTU2 is 1)

**Figure 11.59 Example of Synchronous Clearing in Interval Tb at Crest**  
(Timing (6) in Figure 11.56; Bit WRE of TWCR in MTU2 is 1)

**Figure 11.60 Example of Synchronous Clearing in Dead Time during Down-Counting (Timing (8) in Figure 11.56; Bit WRE of TWCR is 1)**

**Figure 11.61 Example of Synchronous Clearing in Interval Tb at Trough (Timing (11) in Figure 11.56; Bit WRE of TWCR is 1)**

### (o) Suppressing MTU2-MTU2S Synchronous Counter Clearing

In the MTU2S, setting the SCC bit in TWCR to 1 suppresses synchronous counter clearing caused by the MTU2.

Synchronous counter clearing is suppressed only within the interval shown in figure 11.62. When using this function, the MTU2S should be set to complementary PWM mode.

For details of synchronous clearing caused by the MTU2, refer to the description about MTU2S counter clearing caused by MTU2 flag setting source (MTU2-MTU2S synchronous counter clearing) in section 11.4.10, MTU2-MTU2S Synchronous Operation.

**Figure 11.62 MTU2-MTU2S Synchronous Clearing-Suppressed Interval Specified by SCC Bit in TWCR**

- Example of Procedure for Suppressing MTU2-MTU2S Synchronous Counter Clearing

An example of the procedure for suppressing MTU2-MTU2S synchronous counter clearing is shown in figure 11.63.

**Figure 11.63 Example of Procedure for Suppressing MTU2-MTU2S Synchronous Counter Clearing**

- Examples of Suppression of MTU2-MTU2S Synchronous Counter Clearing

Figures 11.64 to 11.67 show examples of operation in which the MTU2S operates in complementary PWM mode and MTU2-MTU2S synchronous counter clearing is suppressed by setting the SCC bit in TWCR in the MTU2S to 1. In the examples shown in figures 11.64 to 11.67, synchronous counter clearing occurs at timing (3), (6), (8), and (11) shown in figure 11.56, respectively.

In these examples, the WRE bit in TWCR of the MTU2S is set to 1.

**Figure 11.64 Example of Synchronous Clearing in Dead Time during Up-Counting**  
(Timing (3) in Figure 11.56; Bit WRE is 1 and Bit SCC is 1 in TWCR of MTU2S)

**Figure 11.65 Example of Synchronous Clearing in Interval  $T_b$  at Crest**  
(Timing (6) in Figure 11.56; Bit WRE is 1 and Bit SCC is 1 in TWCR of MTU2S)

**Figure 11.67 Example of Synchronous Clearing in Interval Tb at Trough (Timing (11) in Figure 11.56; Bit WRE is 1 and Bit SCC is 1 in TWCR of MTU2S)**

### (p) Counter Clearing by TGRA\_3 Compare Match

In complementary PWM mode, by setting the CCE bit in the timer waveform control register (TWCR), it is possible to have TCNT\_3, TCNT\_4, and TCNTS cleared by TGRA\_3 compare match.

Figure 11.68 illustrates an operation example.

- Notes:
1. Use this function only in complementary PWM mode 1 (transfer at crest)
  2. Do not specify synchronous clearing by another channel (do not set the SYNC0 to SYNC4 bits in the timer synchronous register (TSYR) to 1 or the CE0A, CE0B, CE0C, CE0D, CE1A, CE1B, CE1C, and CE1D bits in the timer synchronous clear register (TSYCR) to 1).
  3. Do not set the PWM duty value to H'0000.
  4. Do not set the PSYE bit in timer output control register 1 (TOCR1) to 1.

**Figure 11.68 Example of Counter Clearing Operation by TGRA\_3 Compare Match**

### (q) Example of AC Synchronous Motor (Brushless DC Motor) Drive Waveform Output

In complementary PWM mode, a brushless DC motor can easily be controlled using the timer gate control register (TGCR). Figures 11.69 to 11.72 show examples of brushless DC motor drive waveforms created using TGCR.

When output phase switching for a 3-phase brushless DC motor is performed by means of external signals detected with a Hall element, etc., clear the FB bit in TGCR to 0. In this case, the external signals indicating the polarity position are input to channel 0 timer input pins TIOC0A, TIOC0B, and TIOC0C (set with PFC). When an edge is detected at pin TIOC0A, TIOC0B, or TIOC0C, the output on/off state is switched automatically.

When the FB bit is 1, the output on/off state is switched when the UF, VF, or WF bit in TGCR is cleared to 0 or set to 1.

The drive waveforms are output from the complementary PWM mode 6-phase output pins. With this 6-phase output, in the case of on output, it is possible to use complementary PWM mode output and perform chopping output by setting the N bit or P bit to 1. When the N bit or P bit is 0, level output is selected.

The 6-phase output active level (on output level) can be set with the OLSN and OLSP bits in the timer output control register (TOCR) regardless of the setting of the N and P bits.

**Figure 11.69 Example of Output Phase Switching by External Input (1)**

**Figure 11.70 Example of Output Phase Switching by External Input (2)**

**Figure 11.71 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (1)**

**Figure 11.72 Example of Output Phase Switching by Means of UF, VF, WF Bit Settings (2)**

#### (r) A/D Converter Start Request Setting

In complementary PWM mode, an A/D converter start request can be issued using a TGRA\_3 compare-match, TCNT\_4 underflow (trough), or compare-match on a channel other than channels 3 and 4.

When start requests using a TGRA\_3 compare-match are specified, A/D conversion can be started at the crest of the TCNT\_3 count.

A/D converter start requests can be set by setting the TTGE bit to 1 in the timer interrupt enable register (TIER). To issue an A/D converter start request at a TCNT\_4 underflow (trough), set the TTGE2 bit in TIER\_4 to 1.

### (3) Interrupt Skipping in Complementary PWM Mode

Interrupts TGIA\_3 (at the crest) and TCIV\_4 (at the trough) in channels 3 and 4 can be skipped up to seven times by making settings in the timer interrupt skipping set register (TITCR).

Transfers from a buffer register to a temporary register or a compare register can be skipped in coordination with interrupt skipping by making settings in the timer buffer transfer register (TBTER). For the linkage with buffer registers, refer to description (c), Buffer Transfer Control Linked with Interrupt Skipping, below.

A/D converter start requests generated by the A/D converter start request delaying function can also be skipped in coordination with interrupt skipping by making settings in the timer A/D converter request control register (TADCR). For the linkage with the A/D converter start request delaying function, refer to section 11.4.9, A/D Converter Start Request Delaying Function.

The setting of the timer interrupt skipping setting register (TITCR) must be done while the TGIA\_3 and TCIV\_4 interrupt requests are disabled by the settings of TIER\_3 and TIER\_4 along with under the conditions in which TGFA\_3 and TCFV\_4 flag settings by compare match never occur. Before changing the skipping count, be sure to clear the T3AEN and T4VEN bits to 0 to clear the skipping counter.

#### (a) Example of Interrupt Skipping Operation Setting Procedure

Figure 11.73 shows an example of the interrupt skipping operation setting procedure. Figure 11.74 shows the periods during which interrupt skipping count can be changed.

**Figure 11.73 Example of Interrupt Skipping Operation Setting Procedure**

**Figure 11.74 Periods during which Interrupt Skipping Count can be Changed**

### (b) Example of Interrupt Skipping Operation

Figure 11.75 shows an example of TGIA\_3 interrupt skipping in which the interrupt skipping count is set to three by the 3ACOR bit and the T3AEN bit is set to 1 in the timer interrupt skipping set register (TITCR).

**Figure 11.75 Example of Interrupt Skipping Operation**

### (c) Buffer Transfer Control Linked with Interrupt Skipping

In complementary PWM mode, whether to transfer data from a buffer register to a temporary register and whether to link the transfer with interrupt skipping can be specified with the BTE1 and BTE0 bits in the timer buffer transfer set register (TBTER).

Figure 11.76 shows an example of operation when buffer transfer is suppressed (BTE1 = 0 and BTE0 = 1). While this setting is valid, data is not transferred from the buffer register to the temporary register.

Figure 11.77 shows an example of operation when buffer transfer is linked with interrupt skipping (BTE1 = 1 and BTE0 = 0). While this setting is valid, data is not transferred from the buffer register outside the buffer transfer-enabled period. Depending on the timing of interrupt generation and writing to the buffer register, the timing of transfer from the buffer register to the temporary register and from the temporary register to the general register is one of two types.

Note that the buffer transfer-enabled period depends on the T3AEN and T4VEN bit settings in the timer interrupt skipping set register (TITCR). Figure 11.78 shows the relationship between the T3AEN and T4VEN bit settings in TITCR and buffer transfer-enabled period.

**Note:** This function must always be used in combination with interrupt skipping.

When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that buffer transfer is not linked with interrupt skipping (clear the BTE1 bit in the timer buffer transfer set register (TBTER) to 0). If buffer transfer is linked with interrupt skipping while interrupt skipping is disabled, buffer transfer is never performed.

## [Legend]

- (1) No data is transferred from the buffer register to the temporary register in the buffer transfer-disabled period (bits BTE1 and BTE0 in TBTER are set to 0 and 1, respectively).
- (2) Data is transferred from the temporary register to the general register even in the buffer transfer-disabled period.
- (3) After buffer transfer is enabled, data is transferred from the buffer register to the temporary register.

Note: \* When buffer transfer at the crest is selected.

**Figure 11.76 Example of Operation when Buffer Transfer is Suppressed (BTE1 = 0 and BTE0 = 1)**

(1) When rewriting the buffer register within 1 carrier cycle from TGIA\_3 interrupt

(2) When rewriting the buffer register after passing 1 carrier cycle from TGIA\_3 interrupt

Note: \* Buffer transfer at the crest is selected.  
 The skipping count is set to two.  
 T3AEN is set to 1.

**Figure 11.77 Example of Operation when Buffer Transfer is Linked with Interrupt Skipping (BTE1 = 1 and BTE0 = 0)**

**Figure 11.78 Relationship between Bits T3AEN and T4VEN in TITCR and Buffer Transfer-Enabled Period**

#### (4) Complementary PWM Mode Output Protection Function

Complementary PWM mode output has the following protection functions.

##### (a) Register and Counter Miswrite Prevention Function

With the exception of the buffer registers, which can be rewritten at any time, access by the CPU can be enabled or disabled for the mode registers, control registers, compare registers, and counters used in complementary PWM mode by means of the RWE bit in the timer read/write enable register (TRWER). The applicable registers are some (21 in total) of the registers in channels 3 and 4 shown in the following:

- TCR\_3 and TCR\_4, TMDR\_3 and TMDR\_4, TIORH\_3 and TIORH\_4, TIORL\_3 and TIORL\_4, TIER\_3 and TIER\_4, TCNT\_3 and TCNT\_4, TGRA\_3 and TGRA\_4, TGRB\_3 and TGRB\_4, TOER, TOCR, TGCR, TCDR, and TDDR.

This function enables miswriting due to CPU runaway to be prevented by disabling CPU access to the mode registers, control registers, and counters. When the applicable registers are read in the access-disabled state, undefined values are returned. Writing to these registers is ignored.

### (b) Halting of PWM Output by External Signal

The 6-phase PWM output pins can be set automatically to the high-impedance state by inputting specified external signals. There are four external signal input pins.

See section 13, Port Output Enable 2 (POE2), for details.

### (c) Halting of PWM Output by Oscillation Stop

The 6-phase PWM output pins can detect the clock stop and set the output pin automatically to the high-impedance state. However, the pin state is not guaranteed when the clock starts oscillation again.

See section 4.7, Oscillation Stop Detection, for details.

## 11.4.9 A/D Converter Start Request Delaying Function

A/D converter start requests can be issued in channel 4 by making settings in the timer A/D converter start request control register (TADCR), timer A/D converter start request cycle set registers (TADCORA\_4 and TADCORB\_4), and timer A/D converter start request cycle set buffer registers (TADCOBRA\_4 and TADCOBRB\_4).

The A/D converter start request delaying function compares TCNT\_4 with TADCORA\_4 or TADCORB\_4, and when their values match, the function issues a respective A/D converter start request (TRG4AN or TRG4BN).

A/D converter start requests (TRG4AN and TRG4BN) can be skipped in coordination with interrupt skipping by making settings in the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in TADCR.

- Example of Procedure for Specifying A/D Converter Start Request Delaying Function

Figure 11.79 shows an example of procedure for specifying the A/D converter start request delaying function.

**Figure 11.79 Example of Procedure for Specifying A/D Converter Start Request Delaying Function**

- Basic Operation Example of A/D Converter Start Request Delaying Function

Figure 11.80 shows a basic example of A/D converter request signal (TRG4AN) operation when the trough of TCNT\_4 is specified for the buffer transfer timing and an A/D converter start request signal is output during TCNT\_4 down-counting.

**Figure 11.80 Basic Example of A/D Converter Start Request Signal (TRG4AN) Operation**

- Buffer Transfer

The data in the timer A/D converter start request cycle set registers (TADCORA\_4 and TADCORB\_4) is updated by writing data to the timer A/D converter start request cycle set buffer registers (TADCOBRA\_4 and TADCOBRB\_4). Data is transferred from the buffer registers to the respective cycle set registers at the timing selected with the BF1 and BF0 bits in the timer A/D converter start request control register (TADCR\_4).

- A/D Converter Start Request Delaying Function Linked with Interrupt Skipping

A/D converter start requests (TRG4AN and TRG4BN) can be issued in coordination with interrupt skipping by making settings in the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR).

Figure 11.81 shows an example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT\_4 up-counting and down-counting and A/D converter start requests are linked with interrupt skipping.

Figure 11.82 shows another example of A/D converter start request signal (TRG4AN) operation when TRG4AN output is enabled during TCNT\_4 up-counting and A/D converter start requests are linked with interrupt skipping.

**Note:** This function must be used in combination with interrupt skipping.

When interrupt skipping is disabled (the T3AEN and T4VEN bits in the timer interrupt skipping set register (TITCR) are cleared to 0 or the skipping count set bits (3ACOR and 4VCOR) in TITCR are cleared to 0), make sure that A/D converter start requests are not linked with interrupt skipping (clear the ITA3AE, ITA4VE, ITB3AE, and ITB4VE bits in the timer A/D converter start request control register (TADCR) to 0).

Furthermore, when this function is to be used, set TADCORA\_4 and TADCORB\_4 to a value between H'0002 and the TCDR setting minus two.

**Figure 11.81 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping**

**Figure 11.82 Example of A/D Converter Start Request Signal (TRG4AN) Operation Linked with Interrupt Skipping**

### 11.4.10 MTU2-MTU2S Synchronous Operation

#### (1) MTU2-MTU2S Synchronous Counter Start

The counters in the MTU2 and MTU2S which operate at different clock systems can be started synchronously by making the TCSYSTR settings in the MTU2.

##### (a) Example of MTU2-MTU2S Synchronous Counter Start Setting Procedure

Figure 11.83 shows an example of synchronous counter start setting procedure.

**Figure 11.83 Example of Synchronous Counter Start Setting Procedure**

### (b) Examples of Synchronous Counter Start Operation

Figures 11.84 (1) to (4) show examples of synchronous counter start operation when the clock frequency ratios between the MTU2 and MTU2S are 1:1, 1:2, 1:3, and 1:4, respectively. In these examples, the count clock is set to P $\phi$ /1.

**Figure 11.84 (1) Example of Synchronous Counter Start Operation (MTU2-to-MTU2S Clock Frequency Ratio = 1:1)**

**Figure 11.84 (2) Example of Synchronous Counter Start Operation (MTU2-to-MTU2S  
Clock Frequency Ratio = 1:2)**

**Figure 11.84 (3) Example of Synchronous Counter Start Operation (MTU2-to-MTU2S  
Clock Frequency Ratio = 1:3)**

**Figure 11.84 (4) Example of Synchronous Counter Start Operation (MTU2-to-MTU2S Clock Frequency Ratio = 1:4)**

## (2) MTU2S Counter Clearing Caused by MTU2 Flag Setting Source (MTU2-MTU2S Synchronous Counter Clearing)

The MTU2S counters can be cleared by sources for setting the flags in TSR\_0 to TSR\_2 in the MTU2 through the TSYCR\_S settings in the MTU2S.

### (a) Example of Procedure for Specifying MTU2S Counter Clearing by MTU2 Flag Setting Source

Figure 11.85 shows an example of procedure for specifying MTU2S counter clearing by MTU2 flag setting source.

**Figure 11.85 Example of Procedure for Specifying MTU2S Counter Clearing by MTU2 Flag Setting Source**

### (b) Examples of MTU2S Counter Clearing Caused by MTU2 Flag Setting Source

Figures 11.86 (1) and 11.86 (2) show examples of MTS2S counter clearing caused by MTU2 flag setting source.

**Figure 11.86 (1) Example of MTU2S Counter Clearing Caused by MTU2 Flag Setting Source (1)**

**Figure 11.86 (2) Example of MTU2S Counter Clearing Caused by MTU2 Flag Setting Source (2)**

11.4.11 External Pulse Width Measurement

The pulse widths of up to three external input lines can be measured in channel 5.

(1) Example of External Pulse Width Measurement Setting Procedure

Figure 11.87 Example of External Pulse Width Measurement Setting Procedure

(2) Example of External Pulse Width Measurement

Figure 11.88 Example of External Pulse Width Measurement (Measuring High Pulse Width)

### 11.4.12 Dead Time Compensation

By measuring the delay of the output waveform and reflecting it to duty, the external pulse width measurement function can be used as the dead time compensation function while the complementary PWM is in operation.

**Figure 11.89 Delay in Dead Time in Complementary PWM Operation**

## (1) Example of Dead Time Compensation Setting Procedure

Figure 11.90 shows an example of dead time compensation setting procedure by using three counters in channel 5.

**Figure 11.90 Example of Dead Time Compensation Setting Procedure**

**Figure 11.91 Example of Motor Control Circuit Configuration**

### 11.4.13 TCNT Capture at Crest and/or Trough in Complementary PWM Operation

The TCNT value is captured in TGR at either the crest or trough or at both the crest and trough during complementary PWM operation. The timing for capturing in TGR can be selected by TIOR.

Figure 11.92 shows an example in which TCNT is used as a free-running counter without being cleared, and the TCNT value is captured in TGR at the specified timing (either crest or trough, or both crest and trough).

**Figure 11.92 TCNT Capturing at Crest and/or Trough in Complementary PWM Operation**

## 11.5 Interrupt Sources

### 11.5.1 Interrupt Sources and Priorities

There are three kinds of MTU2 interrupt source; TGR input capture/compare match, TCNT overflow, and TCNT underflow. Each interrupt source has its own status flag and enable/disabled bit, allowing the generation of interrupt request signals to be enabled or disabled individually.

When an interrupt request is generated, the corresponding status flag in TSR is set to 1. If the corresponding enable/disable bit in TIER is set to 1 at this time, an interrupt is requested. The interrupt request is cleared by clearing the status flag to 0.

Relative channel priorities can be changed by the interrupt controller, however the priority order within a channel is fixed. For details, see section 6, Interrupt Controller (INTC).

Table 11.57 lists the MTU2 interrupt sources.

**Table 11.57 MTU2 Interrupts**

| Channel | Name   | Interrupt Source                   | Interrupt Flag | DMAC Activation | Priority  |
|---------|--------|------------------------------------|----------------|-----------------|-----------|
| 0       | TGIA_0 | TGRA_0 input capture/compare match | TGFA_0         | Possible        | High<br>↑ |
|         | TGIB_0 | TGRB_0 input capture/compare match | TGFB_0         | Not possible    |           |
|         | TGIC_0 | TGRC_0 input capture/compare match | TGFC_0         | Not possible    |           |
|         | TGID_0 | TGRD_0 input capture/compare match | TGFD_0         | Not possible    |           |
|         | TCIV_0 | TCNT_0 overflow                    | TCFV_0         | Not possible    |           |
|         | TGIE_0 | TGRE_0 compare match               | TGFE_0         | Not possible    |           |
|         | TGIF_0 | TGRF_0 compare match               | TGFF_0         | Not possible    |           |
| 1       | TGIA_1 | TGRA_1 input capture/compare match | TGFA_1         | Possible        | ↓<br>Low  |
|         | TGIB_1 | TGRB_1 input capture/compare match | TGFB_1         | Not possible    |           |
|         | TCIV_1 | TCNT_1 overflow                    | TCFV_1         | Not possible    |           |
|         | TCIU_1 | TCNT_1 underflow                   | TCFU_1         | Not possible    |           |
| 2       | TGIA_2 | TGRA_2 input capture/compare match | TGFA_2         | Possible        |           |
|         | TGIB_2 | TGRB_2 input capture/compare match | TGFB_2         | Not possible    |           |
|         | TCIV_2 | TCNT_2 overflow                    | TCFV_2         | Not possible    |           |
|         | TCIU_2 | TCNT_2 underflow                   | TCFU_2         | Not possible    |           |
| 3       | TGIA_3 | TGRA_3 input capture/compare match | TGFA_3         | Possible        |           |
|         | TGIB_3 | TGRB_3 input capture/compare match | TGFB_3         | Not possible    |           |
|         | TGIC_3 | TGRC_3 input capture/compare match | TGFC_3         | Not possible    |           |
|         | TGID_3 | TGRD_3 input capture/compare match | TGFD_3         | Not possible    |           |
|         | TCIV_3 | TCNT_3 overflow                    | TCFV_3         | Not possible    |           |
| 4       | TGIA_4 | TGRA_4 input capture/compare match | TGFA_4         | Possible        |           |
|         | TGIB_4 | TGRB_4 input capture/compare match | TGFB_4         | Not possible    |           |
|         | TGIC_4 | TGRC_4 input capture/compare match | TGFC_4         | Not possible    |           |
|         | TGID_4 | TGRD_4 input capture/compare match | TGFD_4         | Not possible    |           |
|         | TCIV_4 | TCNT_4 overflow/underflow          | TCFV_4         | Not possible    |           |
| 5       | TGIU_5 | TGRU_5 input capture/compare match | TGFU_5         | Not possible    |           |
|         | TGIV_5 | TGRV_5 input capture/compare match | TGFV_5         | Not possible    |           |
|         | TGIW_5 | TGRW_5 input capture/compare match | TGFW_5         | Not possible    |           |

Note: This table shows the initial state immediately after a reset. The relative channel priorities can be changed by the interrupt controller.

### (1) Input Capture/Compare Match Interrupt

An interrupt is requested if the TGIE bit in TIER is set to 1 when the TGF flag in TSR is set to 1 by the occurrence of a TGR input capture/compare match on a particular channel. The interrupt request is cleared by clearing the TGF flag to 0. The MTU2 has 21 input capture/compare match interrupts, six for channel 0, four each for channels 3 and 4, two each for channels 1 and 2, and three for channel 5. The TGFE\_0 and TGFF\_0 flags in channel 0 are not set by the occurrence of an input capture.

### (2) Overflow Interrupt

An interrupt is requested if the TCIEV bit in TIER is set to 1 when the TCFV flag in TSR is set to 1 by the occurrence of TCNT overflow on a channel. The interrupt request is cleared by clearing the TCFV flag to 0. The MTU2 has five overflow interrupts, one for each channel.

### (3) Underflow Interrupt

An interrupt is requested if the TCIEU bit in TIER is set to 1 when the TCFU flag in TSR is set to 1 by the occurrence of TCNT underflow on a channel. The interrupt request is cleared by clearing the TCFU flag to 0. The MTU2 has two underflow interrupts, one each for channels 1 and 2.

## 11.5.2 DMAC and DTC Activation

### (1) DTC Activation

The DTC can be activated by the TGR input capture/compare match interrupt in each channel and the overflow interrupt of channel 4. For details, see section 8, Data Transfer Controller (DTC).

In the MTU2, a total of twenty input capture/compare match interrupts and overflow interrupts can be used as DTC activation sources, four each for channels 0 and 3, two each for channels 1 and 2, five for channel 4 and three for channel 5.

### (2) DMAC Activation

The DMAC can be activated by the TGRA input capture/compare match interrupt in each channel. For details, see section 10, Direct Memory Access Controller (DMAC).

In the MTU2, a total of five TGRA input capture/compare match interrupts can be used as DMAC activation sources, one each for channels 0 to 4.

When the DMAC is activation by MTU2, the activation sources are cleared when the DMAC requests the internal bus mastership. Accordingly, depending on the internal bus state, a wait state

of the DMAC transfer may be generated even if the activation sources are cleared. Also, when transferring DMAC burst by MTU2, the setting of bus function extension register (BSCEHR) is required. See section 9.4.8, Bus Function Extending Register (BSCEHR), for details.

### 11.5.3 A/D Converter Activation

The A/D converter can be activated by one of the following three methods in the MTU2. Table 11.58 shows the relationship between interrupt sources and A/D converter start request signals.

#### (1) A/D Converter Activation by TGRA Input Capture/Compare Match or at TCNT\_4 Trough in Complementary PWM Mode

The A/D converter can be activated by the occurrence of a TGRA input capture/compare match in each channel. In addition, if complementary PWM operation is performed while the TTGE2 bit in TIER\_4 is set to 1, the A/D converter can be activated at the trough of TCNT\_4 count (TCNT\_4 = H'0000).

A/D converter start request signal TRGAN is issued to the A/D converter under either one of the following conditions.

- When the TGFA flag in TSR is set to 1 by the occurrence of a TGRA input capture/compare match on a particular channel while the TTGE bit in TIER is set to 1
- When the TCNT\_4 count reaches the trough (TCNT\_4 = H'0000) during complementary PWM operation while the TTGE2 bit in TIER\_4 is set to 1

When either condition is satisfied, if A/D converter start signal TRGAN from the MTU2 is selected as the trigger in the A/D converter, A/D conversion will start.

#### (2) A/D Converter Activation by Compare Match between TCNT\_0 and TGRE\_0

The A/D converter can be activated by generating A/D converter start request signal TRG0N when a compare match occurs between TCNT\_0 and TGRE\_0 in channel 0.

When the TGFE flag in TSR2\_0 is set to 1 by the occurrence of a compare match between TCNT\_0 and TGRE\_0 in channel 0 while the TTGE2 bit in TIER2\_0 is set to 1, A/D converter start request TGR0N is issued to the A/D converter. If A/D converter start signal TGR0N from the MTU2 is selected as the trigger in the A/D converter, A/D conversion will start.

### (3) A/D Converter Activation by A/D Converter Start Request Delaying Function

The A/D converter can be activated by generating A/D converter start request signal TRG4AN or TRG4BN when the TCNT\_4 count matches the TADCORA or TADCORB value if the UT4AE, DT4AE, UT4BE, or DT4BE bit in the A/D converter start request control register (TADCR) is set to 1. For details, refer to section 11.4.9, A/D Converter Start Request Delaying Function.

A/D conversion will start if A/D converter start signal TRG4AN from the MTU2 is selected as the trigger in the A/D converter when TRG4AN is generated or if TRG4BN from the MTU2 is selected as the trigger in the A/D converter when TRG4BN is generated.

**Table 11.58 Interrupt Sources and A/D Converter Start Request Signals**

| Target Registers   | Interrupt Source                        | A/D Converter Start Request Signal |
|--------------------|-----------------------------------------|------------------------------------|
| TGRA_0 and TCNT_0  | Input capture/compare match             | TRGAN                              |
| TGRA_1 and TCNT_1  |                                         |                                    |
| TGRA_2 and TCNT_2  |                                         |                                    |
| TGRA_3 and TCNT_3  |                                         |                                    |
| TGRA_4 and TCNT_4  |                                         |                                    |
| TCNT_4             | TCNT_4 Trough in complementary PWM mode |                                    |
| TGRE_0 and TCNT_0  | Compare match                           | TRG0N                              |
| TADCORA and TCNT_4 |                                         | TRG4AN                             |
| TADCORB and TCNT_4 |                                         | TRG4BN                             |

## 11.6 Operation Timing

### 11.6.1 Input/Output Timing

#### (1) TCNT Count Timing

Figures 11.93 and 94 show TCNT count timing in internal clock operation, and figure 11.95 shows TCNT count timing in external clock operation (normal mode), and figure 11.96 shows TCNT count timing in external clock operation (phase counting mode).

**Figure 11.93 Count Timing in Internal Clock Operation (Channels 0 to 4)**

**Figure 11.94 Count Timing in Internal Clock Operation (Channel 5)**

**Figure 11.95 Count Timing in External Clock Operation (Channels 0 to 4)**

**Figure 11.96 Count Timing in External Clock Operation (Phase Counting Mode)**

## (2) Output Compare Output Timing

A compare match signal is generated in the final state in which TCNT and TGR match (the point at which the count value matched by TCNT is updated). When a compare match signal is generated, the output value set in TIOR is output at the output compare output pin (TIOC pin). After a match between TCNT and TGR, the compare match signal is not generated until the TCNT input clock is generated.

Figure 11.97 shows output compare output timing (normal mode and PWM mode) and figure 11.98 shows output compare output timing (complementary PWM mode and reset synchronous PWM mode).

**Figure 11.97 Output Compare Output Timing (Normal Mode/PWM Mode)**

**Figure 11.98 Output Compare Output Timing**  
(Complementary PWM Mode/Reset Synchronous PWM Mode)

### (3) Input Capture Signal Timing

Figure 11.99 shows input capture signal timing.

**Figure 11.99 Input Capture Input Signal Timing**

#### (4) Timing for Counter Clearing by Compare Match/Input Capture

Figures 11.100 and 101 show the timing when counter clearing on compare match is specified, and figure 11.102 shows the timing when counter clearing on input capture is specified.

**Figure 11.100 Counter Clear Timing (Compare Match) (Channels 0 to 4)**

**Figure 11.101 Counter Clear Timing (Compare Match) (Channel 5)**

**Figure 11.102 Counter Clear Timing (Input Capture) (Channels 0 to 5)**

### (5) Buffer Operation Timing

Figures 11.103 to 11.105 show the timing in buffer operation.

**Figure 11.103 Buffer Operation Timing (Compare Match)**

**Figure 11.104 Buffer Operation Timing (Input Capture)**

**Figure 11.105 Buffer Transfer Timing (when TCNT Cleared)**

## (6) Buffer Transfer Timing (Complementary PWM Mode)

Figures 11.106 to 11.108 show the buffer transfer timing in complementary PWM mode.

**Figure 11.106 Transfer Timing from Buffer Register to Temporary Register (TCNTS Stop)**

**Figure 11.107 Transfer Timing from Buffer Register to Temporary Register (TCNTS Operating)**

**Figure 11.108 Transfer Timing from Temporary Register to Compare Register**

## 11.6.2 Interrupt Signal Timing

### (1) TGF Flag Setting Timing in Case of Compare Match

Figures 11.109 and 110 show the timing for setting of the TGF flag in TSR on compare match, and TGI interrupt request signal timing.

**Figure 11.109 TGI Interrupt Timing (Compare Match)**

**Figure 11.110 TGI Interrupt Timing (Compare Match) (Channel 5)**

## (2) TGF Flag Setting Timing in Case of Input Capture

Figures 11.111 and 112 show the timing for setting of the TGF flag in TSR on input capture, and TGI interrupt request signal timing.

**Figure 11.111 TGI Interrupt Timing (Input Capture) (Channels 0 to 4)**

**Figure 11.112 TGI Interrupt Timing (Input Capture) (Channel 5)**

### (3) TCFV Flag/TCFU Flag Setting Timing

Figure 11.113 shows the timing for setting of the TCFV flag in TSR on overflow, and TCIV interrupt request signal timing.

Figure 11.114 shows the timing for setting of the TCFU flag in TSR on underflow, and TCIU interrupt request signal timing.

**Figure 11.113 TCIV Interrupt Setting Timing**

**Figure 11.114 TCIU Interrupt Setting Timing**

#### (4) Status Flag Clearing Timing

After a status flag is read as 1 by the CPU, it is cleared by writing 0 to it. When the DMAC is activated, the flag is cleared automatically. Figures 11.115 and 116 show the timing for status flag clearing by the CPU, and figure 11.117 shows the timing for status flag clearing by the DMAC.

**Figure 11.115 Timing for Status Flag Clearing by CPU (Channels 0 to 4)**

**Figure 11.116 Timing for Status Flag Clearing by CPU (Channel 5)**

**Figure 11.117 Timing for Status Flag Clearing by DTC Activation (Channels 0 to 4)**

**Figure 11.118 Timing for Status Flag Clearing by DTC Activation (Channel 5)**

**Figure 11.119 Timing for Status Flag Clearing by DMAC Activation**

## 11.7 Usage Notes

### 11.7.1 Module Standby Mode Setting

MTU2 operation can be disabled or enabled using the standby control register. The initial setting is for MTU2 operation to be halted. Register access is enabled by clearing module standby mode. For details, refer to section 30, Power-Down Modes.

### 11.7.2 Input Clock Restrictions

The input clock pulse width must be at least 1.5 states in the case of single-edge detection, and at least 2.5 states in the case of both-edge detection. The MTU2 will not operate properly at narrower pulse widths.

In phase counting mode, the phase difference and overlap between the two input clocks must be at least 1.5 states, and the pulse width must be at least 2.5 states. Figure 11.120 shows the input clock conditions in phase counting mode.

**Figure 11.120 Phase Difference, Overlap, and Pulse Width in Phase Counting Mode**

### 11.7.3 Caution on Period Setting

When counter clearing on compare match is set, TCNT is cleared in the final state in which it matches the TGR value (the point at which the count value matched by TCNT is updated). Consequently, the actual counter frequency is given by the following formula:

- Channel 0 to 4

$$f = \frac{P\phi}{(N + 1)}$$

- Channel 5

$$f = \frac{P\phi}{N}$$

Where    f:        Counter frequency  
           P $\phi$ :      Peripheral clock operating frequency  
           N:        TGR set value

### 11.7.4 Contention between TCNT Write and Clear Operations

If the counter clear signal is generated in the T2 state of a TCNT write cycle, TCNT clearing takes precedence and the TCNT write is not performed.

Figure 11.121 shows the timing in this case.

**Figure 11.121 Contention between TCNT Write and Clear Operations**

### 11.7.5 Contention between TCNT Write and Increment Operations

If incrementing occurs in the T2 state of a TCNT write cycle, the TCNT write takes precedence and TCNT is not incremented.

Figure 11.122 shows the timing in this case.

**Figure 11.122 Contention between TCNT Write and Increment Operations**

### 11.7.6 Contention between TGR Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the TGR write is executed and the compare match signal is also generated.

Figure 11.123 shows the timing in this case.

**Figure 11.123 Contention between TGR Write and Compare Match**

### 11.7.7 Contention between Buffer Register Write and Compare Match

If a compare match occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data after write.

Figure 11.124 shows the timing in this case.

**Figure 11.124 Contention between Buffer Register Write and Compare Match**

### 11.7.8 Contention between Buffer Register Write and TCNT Clear

When the buffer transfer timing is set at the TCNT clear by the buffer transfer mode register (TBTM), if TCNT clear occurs in the T2 state of a TGR write cycle, the data that is transferred to TGR by the buffer operation is the data before write.

Figure 11.125 shows the timing in this case.

**Figure 11.125 Contention between Buffer Register Write and TCNT Clear**

### 11.7.9 Contention between TGR Read and Input Capture

If an input capture signal is generated in the T1 state of a TGR read cycle, the data that is read will be the data in the buffer before input capture transfer for channels 0 to 4, and the data after input capture transfer for channel 5.

Figures 11.126 and 127 show the timing in this case.

**Figure 11.126 Contention between TGR Read and Input Capture (Channels 0 to 4)**

**Figure 11.127 Contention between TGR Read and Input Capture (Channel 5)**

### 11.7.10 Contention between TGR Write and Input Capture

If an input capture signal is generated in the T2 state of a TGR write cycle, the input capture operation takes precedence and the write to TGR is not performed for channels 0 to 4. For channel 5, write to TGR is performed and the input capture signal is generated.

Figures 11.128 and 129 show the timing in this case.

**Figure 11.128 Contention between TGR Write and Input Capture (Channels 0 to 4)**

**Figure 11.129 Contention between TGR Write and Input Capture (Channel 5)**

### 11.7.11 Contention between Buffer Register Write and Input Capture

If an input capture signal is generated in the T2 state of a buffer register write cycle, the buffer operation takes precedence and the write to the buffer register is not performed.

Figure 11.130 shows the timing in this case.

**Figure 11.130 Contention between Buffer Register Write and Input Capture**

### 11.7.12 TCNT2 Write and Overflow/Underflow Contention in Cascade Connection

With timer counters TCNT1 and TCNT2 in a cascade connection, when a contention occurs during TCNT\_1 count (during a TCNT\_2 overflow/underflow) in the T<sub>2</sub> state of the TCNT\_2 write cycle, the write to TCNT\_2 is conducted, and the TCNT\_1 count signal is disabled. At this point, if there is match with TGRA\_1 and the TCNT\_1 value, a compare signal is issued. Furthermore, when the TCNT\_1 count clock is selected as the input capture source of channel 0, TGRA\_0 to D\_0 carry out the input capture operation. In addition, when the compare match/input capture is selected as the input capture source of TGRB\_1, TGRB\_1 carries out input capture operation. The timing is shown in figure 11.131.

For cascade connections, be sure to synchronize settings for channels 1 and 2 when setting TCNT clearing.

**Figure 11.131 TCNT\_2 Write and Overflow/Underflow Contention with Cascade Connection**

### 11.7.13 Counter Value during Complementary PWM Mode Stop

When counting operation is suspended with TCNT\_3 and TCNT\_4 in complementary PWM mode, TCNT\_3 has the timer dead time register (TDDR) value, and TCNT\_4 is held at H'0000.

When restarting complementary PWM mode, counting begins automatically from the initialized state. This explanatory diagram is shown in figure 11.132.

When counting begins in another operating mode, be sure that TCNT\_3 and TCNT\_4 are set to the initial values.

**Figure 11.132 Counter Value during Complementary PWM Mode Stop**

### 11.7.14 Buffer Operation Setting in Complementary PWM Mode

In complementary PWM mode, conduct rewrites by buffer operation for the PWM cycle setting register (TGRA\_3), timer cycle data register (TCDR), and duty setting registers (TGRB\_3, TGRA\_4, and TGRB\_4).

In complementary PWM mode, channel 3 and channel 4 buffers operate in accordance with bit settings BFA and BFB of TMDR\_3. When TMDR\_3's BFA bit is set to 1, TGRC\_3 functions as a buffer register for TGRA\_3. At the same time, TGRC\_4 functions as the buffer register for TGRA\_4, and TCBR functions as the TCDR's buffer register.

### 11.7.15 Reset Sync PWM Mode Buffer Operation and Compare Match Flag

When setting buffer operation for reset sync PWM mode, set the BFA and BFB bits of TMDR\_4 to 0. The TIOC4C pin will be unable to produce its waveform output if the BFA bit of TMDR\_4 is set to 1.

In reset sync PWM mode, the channel 3 and channel 4 buffers operate in accordance with the BFA and BFB bit settings of TMDR\_3. For example, if the BFA bit of TMDR\_3 is set to 1, TGRC\_3 functions as the buffer register for TGRA\_3. At the same time, TGRC\_4 functions as the buffer register for TGRA\_4.

The TGFC bit and TGFD bit of TSR\_3 and TSR\_4 are not set when TGRC\_3 and TGRD\_3 are operating as buffer registers.

Figure 11.133 shows an example of operations for TGR\_3, TGR\_4, TIOC3, and TIOC4, with TMDR\_3's BFA and BFB bits set to 1, and TMDR\_4's BFA and BFB bits set to 0.

**Figure 11.133 Buffer Operation and Compare-Match Flags  
in Reset Synchronous PWM Mode**

### 11.7.16 Overflow Flags in Reset Synchronous PWM Mode

When set to reset synchronous PWM mode, TCNT\_3 and TCNT\_4 start counting when the CST3 bit of TSTR is set to 1. At this point, TCNT\_4's count clock source and count edge obey the TCR\_3 setting.

In reset synchronous PWM mode, with cycle register TGRA\_3's set value at H'FFFF, when specifying TGR3A compare-match for the counter clear source, TCNT\_3 and TCNT\_4 count up to H'FFFF, then a compare-match occurs with TGRA\_3, and TCNT\_3 and TCNT\_4 are both cleared. At this point, TSR's overflow flag TCFV bit is not set.

Figure 11.134 shows a TCFV bit operation example in reset synchronous PWM mode with a set value for cycle register TGRA\_3 of H'FFFF, when a TGRA\_3 compare-match has been specified without synchronous setting for the counter clear source.

**Figure 11.134 Reset Synchronous PWM Mode Overflow Flag**

### 11.7.17 Contention between Overflow/Underflow and Counter Clearing

If overflow/underflow and counter clearing occur simultaneously, the TCFV/TCFU flag in TSR is not set and TCNT clearing takes precedence.

Figure 11.135 shows the operation timing when a TGR compare match is specified as the clearing source, and when H'FFFF is set in TGR.

**Figure 11.135 Contention between Overflow and Counter Clearing**

### 11.7.18 Contention between TCNT Write and Overflow/Underflow

If there is an up-count or down-count in the T2 state of a TCNT write cycle, and overflow/underflow occurs, the TCNT write takes precedence and the TCFV/TCFU flag in TSR is not set.

Figure 11.136 shows the operation timing when there is contention between TCNT write and overflow.

**Figure 11.136 Contention between TCNT Write and Overflow**

### 11.7.19 Cautions on Transition from Normal Operation or PWM Mode 1 to Reset-Synchronized PWM Mode

When making a transition from channel 3 or 4 normal operation or PWM mode 1 to reset-synchronized PWM mode, if the counter is halted with the output pins (TIOC3B, TIOC3D, TIOC4A, TIOC4C, TIOC4B, TIOC4D) in the high-level state, followed by the transition to reset-synchronized PWM mode and operation in that mode, the initial pin output will not be correct.

When making a transition from normal operation to reset-synchronized PWM mode, write H'11 to registers TIORH\_3, TIORL\_3, TIORH\_4, and TIORL\_4 to initialize the output pins to low level output, then set an initial register value of H'00 before making the mode transition.

When making a transition from PWM mode 1 to reset-synchronized PWM mode, first switch to normal operation, then initialize the output pins to low level output and set an initial register value of H'00 before making the transition to reset-synchronized PWM mode.

### 11.7.20 Output Level in Complementary PWM Mode and Reset-Synchronized PWM Mode

When channels 3 and 4 are in complementary PWM mode or reset-synchronized PWM mode, the PWM waveform output level is set with the OLSP and OLSN bits in the timer output control register (TOCR). In the case of complementary PWM mode or reset-synchronized PWM mode, TIOR should be set to H'00.

### 11.7.21 Interrupts in Module Standby Mode

If module standby mode is entered when an interrupt has been requested, it will not be possible to clear the CPU interrupt source or the DMAC activation source. Interrupts should therefore be disabled before entering module standby mode.

### 11.7.22 Simultaneous Capture of TCNT\_1 and TCNT\_2 in Cascade Connection

When timer counters 1 and 2 (TCNT\_1 and TCNT\_2) are operated as a 32-bit counter in cascade connection, the cascade counter value cannot be captured successfully even if input-capture input is simultaneously done to TIOC1A and TIOC2A or to TIOC1B and TIOC2B. This is because the input timing of TIOC1A and TIOC2A or of TIOC1B and TIOC2B may not be the same when external input-capture signals to be input into TCNT\_1 and TCNT\_2 are taken in synchronization with the internal clock. For example, TCNT\_1 (the counter for upper 16 bits) does not capture the count-up value by overflow from TCNT\_2 (the counter for lower 16 bits) but captures the count value before the count-up. In this case, the values of TCNT\_1 = H'FFF1 and TCNT\_2 = H'0000 should be transferred to TGRA\_1 and TGRA\_2 or to TGRB\_1 and TGRB\_2, but the values of TCNT\_1 = H'FFF0 and TCNT\_2 = H'0000 are erroneously transferred.

The MTU2 has a new function that allows simultaneous capture of TCNT\_1 and TCNT\_2 with a single input-capture as the trigger. This function allows reading of the 32-bit counter such that TCNT\_1 and TCNT\_2 are captured at the same time. For details, see section 11.3.8, Timer Input Capture Control Register (TICCR).

### 11.7.23 Note on Output Waveform Control at Synchronous Counter Clearing in Complementary PWM Mode

If either condition (1) or (2) is satisfied when output waveform control at synchronous counter clearing is enabled (WRE bit in TWCR is 1) in complementary PWM mode, the following phenomena occur.

- The dead time of the PWM output pins becomes shorter (or disappears).
- An active level is output from a PWM reverse phase output pin during a period other than the active level output period.

Condition (1) In the initial output suppression period (10), synchronous clearing is performed while the PWM output is in the dead time (figure 11.137).

Condition (2) In the initial output suppression periods (10) and (11), synchronous clearing is performed while  $TGRB\_3 \leq TDDR$ ,  $TGRA\_4 \leq TDDR$ , or  $TGRB\_4 \leq TDDR$  is satisfied (figure 11.138).

**Figure 11.137 Example of Synchronous Clearing under Condition (1)**

**Figure 11.138 Example of Synchronous Clearing under Condition (2)**

The above phenomena can be avoided by the following method.

Perform synchronous clearing after compare registers TGRB\_3, TGRA\_4, and TGRB\_4 are all set to be at least twice of the setting of the timer dead time data register (TDDR).

## 11.8 MTU2 Output Pin Initialization

### 11.8.1 Operating Modes

The MTU2 has the following six operating modes. Waveform output is possible in all of these modes.

- Normal mode (channels 0 to 4)
- PWM mode 1 (channels 0 to 4)
- PWM mode 2 (channels 0 to 2)
- Phase counting modes 1 to 4 (channels 1 and 2)
- Complementary PWM mode (channels 3 and 4)
- Reset-synchronized PWM mode (channels 3 and 4)

The MTU2 output pin initialization method for each of these modes is described in this section.

### 11.8.2 Reset Start Operation

The MTU2 output pins (TIOC\*) are initialized low by a reset and in standby mode. Since MTU2 pin function selection is performed by the pin function controller (PFC), when the PFC is set, the MTU2 pin states at that point are output to the ports. When MTU2 output is selected by the PFC immediately after a reset, the MTU2 output initial level, low, is output directly at the port. When the active level is low, the system will operate at this point, and therefore the PFC setting should be made after initialization of the MTU2 output pins is completed.

Note: Channel number and port notation are substituted for \*.

### 11.8.3 Operation in Case of Re-Setting Due to Error during Operation, etc.

If an error occurs during MTU2 operation, MTU2 output should be cut by the system. Cutoff is performed by switching the pin output to port output with the PFC and outputting the inverse of the active level. For large-current pins, output can also be cut by hardware, using port output enable (POE). The pin initialization procedures for re-setting due to an error during operation, etc., and the procedures for restarting in a different mode after re-setting, are shown below.

The MTU2 has six operating modes, as stated above. There are thus 36 mode transition combinations, but some transitions are not available with certain channel and mode combinations. Possible mode transition combinations are shown in table 11.59.

**Table 11.59 Mode Transition Combinations**

| Before | After  |      |      |      |           |      |
|--------|--------|------|------|------|-----------|------|
|        | Normal | PWM1 | PWM2 | PCM  | CPWM      | RPWM |
| Normal | (1)    | (2)  | (3)  | (4)  | (5)       | (6)  |
| PWM1   | (7)    | (8)  | (9)  | (10) | (11)      | (12) |
| PWM2   | (13)   | (14) | (15) | (16) | None      | None |
| PCM    | (17)   | (18) | (19) | (20) | None      | None |
| CPWM   | (21)   | (22) | None | None | (23) (24) | (25) |
| RPWM   | (26)   | (27) | None | None | (28)      | (29) |

[Legend]

Normal: Normal mode

PWM1: PWM mode 1

PWM2: PWM mode 2

PCM: Phase counting modes 1 to 4

CPWM: Complementary PWM mode

RPWM: Reset-synchronized PWM mode

### 11.8.4 Overview of Initialization Procedures and Mode Transitions in Case of Error during Operation, etc.

- When making a transition to a mode (Normal, PWM1, PWM2, PCM) in which the pin output level is selected by the timer I/O control register (TIOR) setting, initialize the pins by means of a TIOR setting.
- In PWM mode 1, since a waveform is not output to the TIOC\*B (TIOC \*D) pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 1.
- In PWM mode 2, since a waveform is not output to the cycle register pin, setting TIOR will not initialize the pins. If initialization is required, carry it out in normal mode, then switch to PWM mode 2.
- In normal mode or PWM mode 2, if TGRC and TGRD operate as buffer registers, setting TIOR will not initialize the buffer register pins. If initialization is required, clear buffer mode, carry out initialization, then set buffer mode again.
- In PWM mode 1, if either TGRC or TGRD operates as a buffer register, setting TIOR will not initialize the TGRC pin. To initialize the TGRC pin, clear buffer mode, carry out initialization, then set buffer mode again.
- When making a transition to a mode (CPWM, RPWM) in which the pin output level is selected by the timer output control register (TOCR) setting, switch to normal mode and perform initialization with TIOR, then restore TIOR to its initial value, and temporarily disable channel 3 and 4 output with the timer output master enable register (TOER). Then operate the unit in accordance with the mode setting procedure (TOCR setting, TMDR setting, TOER setting).

Note: Channel number is substituted for \* indicated in this article.

Pin initialization procedures are described below for the numbered combinations in table 11.59. The active level is assumed to be low.

### (1) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.139 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in normal mode after re-setting.

**Figure 11.139 Error Occurrence in Normal Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. After a reset, the TMDR setting is for normal mode.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Not necessary when restarting in normal mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (2) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.140 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.140 Error Occurrence in Normal Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.139.

11. Set PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized. If initialization is required, initialize in normal mode, then switch to PWM mode 1.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (3) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 11.141 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.141 Error Occurrence in Normal Mode, Recovery in PWM Mode 2**

1 to 10 are the same as in figure 11.139.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized. If initialization is required, initialize in normal mode, then switch to PWM mode 2.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

#### (4) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.142 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in phase counting mode after re-setting.

**Figure 11.142 Error Occurrence in Normal Mode, Recovery in Phase Counting Mode**

1 to 10 are the same as in figure 11.139.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

**Note:** Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

### (5) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.143 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.143 Error Occurrence in Normal Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.139.

11. Initialize the normal mode waveform generation section with TIOR.
12. Disable operation of the normal mode waveform generation section with TIOR.
13. Disable channel 3 and 4 output with TOER.
14. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
15. Set complementary PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set MTU2 output with the PFC.
18. Operation is restarted by TSTR.

## (6) Operation when Error Occurs during Normal Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.144 shows an explanatory diagram of the case where an error occurs in normal mode and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.144 Error Occurrence in Normal Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 13 are the same as in figure 11.139.

14. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
15. Set reset-synchronized PWM.
16. Enable channel 3 and 4 output with TOER.
17. Set MTU2 output with the PFC.
18. Operation is restarted by TSTR.

## (7) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Normal Mode

Figure 11.145 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in normal mode after re-setting.

**Figure 11.145 Error Occurrence in PWM Mode 1, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set PWM mode 1.
3. For channels 3 and 4, enable output with TOER before initializing the pins with TIOR.
4. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 1, the TIOC\*B side is not initialized.)
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. Output goes low on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR.
11. Set normal mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (8) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 1

Figure 11.146 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.146 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.145.

11. Not necessary when restarting in PWM mode 1.
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (9) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in PWM Mode 2

Figure 11.147 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.147 Error Occurrence in PWM Mode 1, Recovery in PWM Mode 2**

1 to 10 are the same as in figure 11.145.

11. Set PWM mode 2.
12. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

Note: PWM mode 2 can only be set for channels 0 to 2, and therefore TOER setting is not necessary.

### (10) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.148 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in phase counting mode after re-setting.

**Figure 11.148 Error Occurrence in PWM Mode 1, Recovery in Phase Counting Mode**

1 to 10 are the same as in figure 11.145.

11. Set phase counting mode.
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

Note: Phase counting mode can only be set for channels 1 and 2, and therefore TOER setting is not necessary.

### (11) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.149 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.149 Error Occurrence in PWM Mode 1, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.145.

11. Set normal mode for initialization of the normal mode waveform generation section.
12. Initialize the PWM mode 1 waveform generation section with TIOR.
13. Disable operation of the PWM mode 1 waveform generation section with TIOR.
14. Disable channel 3 and 4 output with TOER.
15. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
16. Set complementary PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set MTU2 output with the PFC.
19. Operation is restarted by TSTR.

## (12) Operation when Error Occurs during PWM Mode 1 Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.150 shows an explanatory diagram of the case where an error occurs in PWM mode 1 and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.150 Error Occurrence in PWM Mode 1, Recovery in Reset-Synchronized PWM Mode**

1 to 14 are the same as in figure 11.149.

15. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
16. Set reset-synchronized PWM.
17. Enable channel 3 and 4 output with TOER.
18. Set MTU2 output with the PFC.
19. Operation is restarted by TSTR.

### (13) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Normal Mode

Figure 11.151 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in normal mode after re-setting.

**Figure 11.151 Error Occurrence in PWM Mode 2, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set PWM mode 2.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence. In PWM mode 2, the cycle register pins are not initialized. In the example, TIOC \*A is the cycle register.)
4. Set MTU2 output with the PFC.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the PFC and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set normal mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

#### (14) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 1

Figure 11.152 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.152 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 1**

1 to 9 are the same as in figure 11.151.

10. Set PWM mode 1.

11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC\*B side is not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (15) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in PWM Mode 2

Figure 11.153 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.153 Error Occurrence in PWM Mode 2, Recovery in PWM Mode 2**

1 to 9 are the same as in figure 11.151.

10. Not necessary when restarting in PWM mode 2.

11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (16) Operation when Error Occurs during PWM Mode 2 Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.154 shows an explanatory diagram of the case where an error occurs in PWM mode 2 and operation is restarted in phase counting mode after re-setting.

**Figure 11.154 Error Occurrence in PWM Mode 2, Recovery in Phase Counting Mode**

1 to 9 are the same as in figure 11.151.

10. Set phase counting mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

### (17) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.155 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in normal mode after re-setting.

**Figure 11.155 Error Occurrence in Phase Counting Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Set phase counting mode.
3. Initialize the pins with TIOR. (The example shows initial high output, with low output on compare-match occurrence.)
4. Set MTU2 output with the PFC.
5. The count operation is started by TSTR.
6. Output goes low on compare-match occurrence.
7. An error occurs.
8. Set port output with the PFC and output the inverse of the active level.
9. The count operation is stopped by TSTR.
10. Set in normal mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

### (18) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.156 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.156 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 1**

1 to 9 are the same as in figure 11.155.

10. Set PWM mode 1.

11. Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

### (19) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in PWM Mode 2

Figure 11.157 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in PWM mode 2 after re-setting.

**Figure 11.157 Error Occurrence in Phase Counting Mode, Recovery in PWM Mode 2**

1 to 9 are the same as in figure 11.155.

10. Set PWM mode 2.

11. Initialize the pins with TIOR. (In PWM mode 2, the cycle register pins are not initialized.)

12. Set MTU2 output with the PFC.

13. Operation is restarted by TSTR.

## (20) Operation when Error Occurs during Phase Counting Mode Operation, and Operation is Restarted in Phase Counting Mode

Figure 11.158 shows an explanatory diagram of the case where an error occurs in phase counting mode and operation is restarted in phase counting mode after re-setting.

**Figure 11.158 Error Occurrence in Phase Counting Mode, Recovery in Phase Counting Mode**

1 to 9 are the same as in figure 11.155.

10. Not necessary when restarting in phase counting mode.
11. Initialize the pins with TIOR.
12. Set MTU2 output with the PFC.
13. Operation is restarted by TSTR.

## (21) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.159 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in normal mode after re-setting.

**Figure 11.159 Error Occurrence in Complementary PWM Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
3. Set complementary PWM.
4. Enable channel 3 and 4 output with TOER.
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. The complementary PWM waveform is output on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR. (MTU2 output becomes the complementary PWM output initial value.)
11. Set normal mode. (MTU2 output goes low.)
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (22) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.160 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.160 Error Occurrence in Complementary PWM Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.159.

11. Set PWM mode 1. (MTU2 output goes low.)
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

### (23) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.161 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using the cycle and duty settings at the time the counter was stopped).

**Figure 11.161 Error Occurrence in Complementary PWM Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.159.

11. Set MTU2 output with the PFC.
12. Operation is restarted by TSTR.
13. The complementary PWM waveform is output on compare-match occurrence.

## (24) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.162 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in complementary PWM mode after re-setting (when operation is restarted using completely new cycle and duty settings).

**Figure 11.162 Error Occurrence in Complementary PWM Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.159.

- Set normal mode and make new settings. (MTU2 output goes low.)
- Disable channel 3 and 4 output with TOER.
- Select the complementary PWM mode output level and cyclic output enabling/disabling with TOCR.
- Set complementary PWM.
- Enable channel 3 and 4 output with TOER.
- Set MTU2 output with the PFC.
- Operation is restarted by TSTR.

## (25) Operation when Error Occurs during Complementary PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.163 shows an explanatory diagram of the case where an error occurs in complementary PWM mode and operation is restarted in reset-synchronized PWM mode.

**Figure 11.163 Error Occurrence in Complementary PWM Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 10 are the same as in figure 11.159.

11. Set normal mode. (MTU2 output goes low.)
12. Disable channel 3 and 4 output with TOER.
13. Select the reset-synchronized PWM mode output level and cyclic output enabling/disabling with TOCR.
14. Set reset-synchronized PWM.
15. Enable channel 3 and 4 output with TOER.
16. Set MTU2 output with the PFC.
17. Operation is restarted by TSTR.

## (26) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Normal Mode

Figure 11.164 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in normal mode after re-setting.

**Figure 11.164 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Normal Mode**

1. After a reset, MTU2 output is low and ports are in the high-impedance state.
2. Select the reset-synchronized PWM output level and cyclic output enabling/disabling with TOCR.
3. Set reset-synchronized PWM.
4. Enable channel 3 and 4 output with TOER.
5. Set MTU2 output with the PFC.
6. The count operation is started by TSTR.
7. The reset-synchronized PWM waveform is output on compare-match occurrence.
8. An error occurs.
9. Set port output with the PFC and output the inverse of the active level.
10. The count operation is stopped by TSTR. (MTU2 output becomes the reset-synchronized PWM output initial value.)
11. Set normal mode. (MTU2 positive phase output is low, and negative phase output is high.)
12. Initialize the pins with TIOR.
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (27) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in PWM Mode 1

Figure 11.165 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in PWM mode 1 after re-setting.

**Figure 11.165 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in PWM Mode 1**

1 to 10 are the same as in figure 11.164.

11. Set PWM mode 1. (MTU2 positive phase output is low, and negative phase output is high.)
12. Initialize the pins with TIOR. (In PWM mode 1, the TIOC \*B side is not initialized.)
13. Set MTU2 output with the PFC.
14. Operation is restarted by TSTR.

## (28) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Complementary PWM Mode

Figure 11.166 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in complementary PWM mode after re-setting.

**Figure 11.166 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Complementary PWM Mode**

1 to 10 are the same as in figure 11.164.

11. Disable channel 3 and 4 output with TOER.
12. Select the complementary PWM output level and cyclic output enabling/disabling with TOCR.
13. Set complementary PWM. (The MTU2 cyclic output pin goes low.)
14. Enable channel 3 and 4 output with TOER.
15. Set MTU2 output with the PFC.
16. Operation is restarted by TSTR.

## (29) Operation when Error Occurs during Reset-Synchronized PWM Mode Operation, and Operation is Restarted in Reset-Synchronized PWM Mode

Figure 11.167 shows an explanatory diagram of the case where an error occurs in reset-synchronized PWM mode and operation is restarted in reset-synchronized PWM mode after re-setting.

**Figure 11.167 Error Occurrence in Reset-Synchronized PWM Mode, Recovery in Reset-Synchronized PWM Mode**

1 to 10 are the same as in figure 11.164.

11. Set MTU2 output with the PFC.
12. Operation is restarted by TSTR.
13. The reset-synchronized PWM waveform is output on compare-match occurrence.

## Section 12 Multi-Function Timer Pulse Unit 2S (MTU2S)

This LSI has an on-chip multi-function timer pulse unit 2S (MTU2S) that comprises three 16-bit timer channels. The MTU2S includes channels 3 to 5 of the MTU2. For details, refer to section 11, Multi-Function Timer Pulse Unit 2 (MTU2). To distinguish from the MTU2, "S" is added to the end of the MTU2S input/output pin and register names. For example, TIOC3A is called TIOC3AS and TGRA\_3 is called TGRA\_3S in this section.

The MTU2S can operate at 100 MHz max. for complementary PWM output functions or at 50 MHz max. for the other functions.

**Table 12.1 MTU2S Functions**

| Item                                   | Channel 3                                                                                     | Channel 4                                                                                     | Channel 5                                                  |

## 12.2 Register Descriptions

The MTU2S has the following registers. For details on register addresses and register states during each process, refer to section 32, List of Registers. To distinguish registers in each channel, an underscore and the channel number are added as a suffix to the register name; TCR for channel 3 is expressed as TCR\_3S.

**Table 12.3 Register Configuration**

| Register Name                         | Abbrevia-<br>tion | R/W | Initial<br>value | Address    | Access<br>Size |
|---------------------------------------|-------------------|-----|------------------|------------|----------------|
| Timer control register_3S             | TCR_3S            | R/W | H'00             | H'FFFE4A00 | 8, 16, 32      |
| Timer control register_4S             | TCR_4S            | R/W | H'00             | H'FFFE4A01 | 8              |
| Timer mode register_3S                | TMDR_3S           | R/W | H'00             | H'FFFE4A02 | 8, 16          |
| Timer mode register_4S                | TMDR_4S           | R/W | H'00             | H'FFFE4A03 | 8              |
| Timer I/O control register H_3S       | TIORH_3S          | R/W | H'00             | H'FFFE4A04 | 8, 16, 32      |
| Timer I/O control register L_3S       | TIORL_3S          | R/W | H'00             | H'FFFE4A05 | 8              |

Note: \* For details on the above registers, see section 11.3.9, Timer Synchronous Clear Register S (TSYCRS) and figure 11.85, Example of Procedure for Specifying MTU2S Counter Clearing by MTU2 Flag Setting Source in section 11, Multi-Function Timer Pulse Unit 2 (MTU2).

## Section 13 Port Output Enable 2 (POE2)

The port output enable 2 (POE2) can be used to place the high-current pins (PE9/TIOC3B, PE11/TIOC3D, PE12/TIOC4A, PE13/TIOC4B, PE14/TIOC4C, PE15/TIOC4D, PE0/TIOC4AS, PE1/TIOC4BS, PE2/TIOC4CS, PE3/TIOC4DS, PE5/TIOC3BS, PE6/TIOC3DS, PD15/TIOC4DS, PD14/TIOC4CS, PD13/TIOC4BS, PD12/TIOC4AS, PD11/TIOC3DS, PD10/TIOC3BS, PD24/TIOC4DS, PD25/TIOC4CS, PD26/TIOC4BS, PD27/TIOC4AS, PD28/TIOC3DS, and PD29/TIOC3BS) and the pins for channel 0 of the MTU2 (PE0/TIOC0A, PE1/TIOC0B, PE2/TIOC0C, PE3/TIOC0D, PB1/TIOC0A, PB2/TIOC0B, PB3/TIOC0C, and PB4/TIOC0D) in high-impedance state, depending on the change on the POE0 to POE4 and POE8 input pins and the output status of the high-current pins, or by modifying register settings. It can also simultaneously generate interrupt requests.

### 13.1 Features

- Each of the  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  input pins can be set for falling edge,  $P\phi/8 \times 16$ ,  $P\phi/16 \times 16$ , or  $P\phi/128 \times 16$  low-level sampling.
- High-current pins and the pins for channel 0 of the MTU2 can be placed in high-impedance state by  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  pins falling-edge or low-level sampling.
- High-current pins can be placed in high-impedance state when the high-current pin output levels are compared and simultaneous active-level output continues for one cycle or more.
- High-current pins and the pins for channel 0 of the MTU2 can be placed in high-impedance state by modifying the POE2 register settings.
- Interrupts can be generated by input-level sampling or output-level comparison results.

The POE2 has input level detection circuits, output level comparison circuits, and a high-impedance request/interrupt request generating circuit as shown in the block diagram of figure 13.1.

Figure 13.1 shows a block diagram of the POE2.

**Figure 13.1 Block Diagram of POE2**

## 13.2 Input/Output Pins

**Table 13.1 Pin Configuration**

| Pin Name                                | Symbol                                               | I/O   | Function                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------|------------------------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### 13.3 Register Descriptions

The POE2 has the following registers.

All these registers are initialized by a power-on reset, but are not initialized by a manual reset or in sleep mode, software standby mode, or module standby mode.

**Table 13.3 Register Configuration**

| Register Name                          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------------------------|--------------|-----|---------------|------------|-------------|
| Input level control/status register 1  | ICSR1        | R/W | H'0000        | H'FFFE5000 | 16          |
| Output level control/status register 1 | OCSR1        | R/W | H'0000        | H'FFFE5002 | 16          |
| Input level control/status register 2  | ICSR2        | R/W | H'0000        | H'FFFE5004 | 16          |

### 13.3.1 Input Level Control/Status Register 1 (ICSR1)

ICSR1 is a 16-bit readable/writable register that selects the  $\overline{\text{POE0}}$ ,  $\overline{\text{POE1}}$ ,  $\overline{\text{POE2}}$ , and  $\overline{\text{POE3}}$  pin input modes, controls the enable/disable of interrupts, and indicates status.

- Notes: 1. Only 0 can be written to clear the flag after 1 is read.
2. Can be modified only once after a power-on reset.

### 13.3.2 Output Level Control/Status Register 1 (OCSR1)

OCSR1 is a 16-bit readable/writable register that controls the enable/disable of both output level comparison and interrupts, and indicates status.

2. Can be modified only once after a power-on reset.

### 13.3.3 Input Level Control/Status Register 2 (ICSR2)

ICSR2 is a 16-bit readable/writable register that selects the  $\overline{\text{POE4}}$  to  $\overline{\text{POE7}}$  pin input modes, controls the enable/disable of interrupts, and indicates status.

Notes: 1. Only 0 can be written to clear the flag after 1 is read.  
2. Can be modified only once after a power-on reset.

### 13.3.4 Output Level Control/Status Register 2 (OCSR2)

OCSR2 is a 16-bit readable/writable register that controls the enable/disable of both output level comparison and interrupts, and indicates status.

2. Can be modified only once after a power-on reset.

### 13.3.5 Input Level Control/Status Register 3 (ICSR3)

ICSR3 is a 16-bit readable/writable register that selects the  $\overline{\text{POE8}}$  pin input mode, controls the enable/disable of interrupts, and indicates status.

### 13.3.8 Port Output Enable Control Register 2 (POECR2)

POECR2 is a 16-bit readable/writable register that controls high-impedance state of the pins.

### 13.4.1 Input Level Detection Operation

If the input conditions set by ICSR1 to ICSR3 occur on the  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  pins, the high-current pins and the pins for channel 0 of the MTU2 are placed in high-impedance state. Note however, that these high-current and MTU2 pins enter high-impedance state only when general input/output function, MTU2 function, or MTU2S function is selected for these pins.

#### (1) Falling Edge Detection

When a change from a high to low level is input to the  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  pins, the high-current pins and the pins for channel 0 of the MTU2 are placed in high-impedance state.

Figure 13.2 shows the sample timing after the level changes in input to the  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  pins until the respective pins enter high-impedance state.

**Figure 13.2 Falling Edge Detection****(2) Low-Level Detection**

Figure 13.3 shows the low-level detection operation. Sixteen continuous low levels are sampled with the sampling clock selected by ICSR1 to ICSR3. If even one high level is detected during this interval, the low level is not accepted.

The timing when the high-current pins enter the high-impedance state after the sampling clock is input is the same in both falling-edge detection and in low-level detection.

**Figure 13.3 Low-Level Detection Operation**

### 13.4.2 Output-Level Compare Operation

Figure 13.4 shows an example of the output-level compare operation for the combination of TIOC3B and TIOC3D. The operation is the same for the other pin combinations.

**Figure 13.4 Output-Level Compare Operation**

### 13.4.3 Release from High-Impedance State

High-current pins that have entered high-impedance state due to input-level detection can be released either by returning them to their initial state with a power-on reset, or by clearing all of the flags in bits 15 to 12 (POE8F, POE4F to POE0F) of ICSR1 to ICSR3. However, note that when low-level sampling is selected by bits 7 to 0 in ICSR1 to ICSR3, just writing 0 to a flag is ignored (the flag is not cleared); flags can be cleared by writing 0 to it only after a high level is input to one of the  $\overline{\text{POE0}}$  to  $\overline{\text{POE4}}$  and  $\overline{\text{POE8}}$  pins and is sampled.

High-current pins that have entered high-impedance state due to output-level detection can be released either by returning them to their initial state with a power-on reset, or by clearing the flag in bit 15 (OCF1 and OCF2) in OCSR1 and OCSR2. However, note that just writing 0 to a flag is ignored (the flag is not cleared); flags can be cleared only after an inactive level is output from the high-current pins. Inactive-level outputs can be achieved by setting the MTU2 and MTU2S internal registers.

## 13.5 Interrupts

The POE2 issues a request to generate an interrupt when the specified condition is satisfied during input level detection or output level comparison. Table 13.5 shows the interrupt sources and their conditions.

**Table 13.5 Interrupt Sources and Conditions**

| <b>Name</b> | <b>Interrupt Source</b>   | <b>Interrupt Flag</b>                | <b>Condition</b>                                                                                                    |
|-------------|---------------------------|--------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| OEI1        | Output enable interrupt 1 | POE3F, POE2F, POE1F, POE0F, and OSF1 | $\text{PIE1} \bullet (\text{POE3F} + \text{POE2F} + \text{POE1F} + \text{POE0F}) + \text{OIE1} \bullet \text{OSF1}$ |
| OEI2        | Output enable interrupt 2 | POE8F                                | $\text{PIE3} \bullet \text{POE8F}$                                                                                  |
| OEI3        | Output enable interrupt 3 | POE4F and OSF2                       | $\text{PIE2} \bullet \text{POE4F} + \text{OIE2} \bullet \text{OSF2}$                                                |

## 13.6 Usage Notes

### 13.6.1 Pins States when the Watchdog Timer has Issued a Power-on Reset

A power-on reset issued from the watchdog timer (WDT) initializes the pin-function controller (PFC) and all I/O port pins thus become general-purpose inputs in accord with the initial PFC settings. However, when a power-on reset is issued while the port-output enable (POE) setting is for high-impedance handling by the pins, the pins remain in the output state for an interval of one cycle of the peripheral clock ( $P\phi$ ) before switching to operation as general-purpose inputs.

The same condition applies when the WDT issues a power-on reset and short-circuit detection by the MTU2 has led to high-impedance handling by a pin.

Figure 13.5 shows the situation where timer output has been selected and the WDT issues a power-on reset while high-impedance handling is in progress due to the POE input.

**Figure 13.5 Pin States when the Watchdog Timer Issues a Power-on Reset**

### 13.6.2 Input Pins

When the POE function is to be used, input a logical 1 to the POE0 to POE4 and POE8 pins by the time the PFC is set for POE input.

## Section 14 Compare Match Timer (CMT)

This LSI has an on-chip compare match timer (CMT) consisting of a two-channel 16-bit timer. The CMT has a 16-bit counter, and can generate interrupts at set intervals.

### 14.1 Features

- Independent selection of four counter input clocks at two channels  
Any of four internal clocks (P $\phi$ /8, P $\phi$ /32, P $\phi$ /128, and P $\phi$ /512) can be selected.
- Selection of DTC/DMA transfer request or interrupt request generation on compare match by DTC/DMA setting
- When not in use, the CMT can be stopped by halting its clock supply to reduce power consumption.

Figure 14.1 shows a block diagram of CMT.

**Figure 14.1 Block Diagram of CMT**

## 14.2 Register Descriptions

The CMT has the following registers.

**Table 14.1 Register Configuration**

| Channel | Register Name                                 | Abbreviation | R/W    | Initial Value | Address   | Access Size |
|---------|-----------------------------------------------|--------------|--------|---------------|-----------|-------------|
| Common  | Compare match timer start register            | CMSTR        | R/W    | H'0000        | H'FFFE000 | 16          |
| 0       | Compare match timer control/status register_0 | CMCSR_0      | R/(W)* | H'0000        | H'FFFE002 | 16          |
|         | Compare match counter_0                       | CMCNT_0      | R/W    | H'0000        | H'FFFE004 | 16          |
|         | Compare match constant register_0             | CMCOR_0      | R/W    | H'FFFF        | H'FFFE006 | 16          |
| 1       | Compare match timer control/status register_1 | CMCSR_1      | R/(W)* | H'0000        | H'FFFE008 | 16          |
|         | Compare match counter_1                       | CMCNT_1      | R/W    | H'0000        | H'FFFE00A | 16          |
|         | Compare match constant register_1             | CMCOR_1      | R/W    | H'FFFF        | H'FFFE00C | 16          |

14.2.1 Compare Match Timer Start Register (CMSTR)

CMSTR is a 16-bit register that selects whether compare match counter (CMCNT) operates or is stopped.

CMSTR is initialized to H'0000 by a power-on reset or in module standby mode, but retains its previous value in software standby mode.

## 14.2.2 Compare Match Timer Control/Status Register (CMCSR)

CMCSR is a 16-bit register that indicates compare match generation, enables or disables interrupts, and selects the counter input clock.

CMCSR is initialized to H'0000 by a power-on reset or in module standby mode, but retains its previous value in software standby mode.

|                |    |    |    |    |    |    |   |   |        |      |   |   |   |   |          |     |
|----------------|----|----|----|----|----|----|---|---|--------|------|---|---|---|---|----------|-----|
| Bit:           | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7      | 6    | 5 | 4 | 3 | 2 | 1        | 0   |
|                | -  | -  | -  | -  | -  | -  | - | - | CMF    | CMIE | - | - | - | - | CKS[1:0] |     |

Note: \* Only 0 can be written to clear the flag after 1 is read.

### 14.2.3 Compare Match Counter (CMCNT)

CMCNT is a 16-bit register used as an up-counter. When the counter input clock is selected with bits CKS[1:0] in CMCSR, and the STR bit in CMSTR is set to 1, CMCNT starts counting using the selected clock. When the value in CMCNT and the value in compare match constant register (CMCOR) match, CMCNT is cleared to H'0000 and the CMF flag in CMCSR is set to 1.

CMCNT is initialized to H'0000 by a power-on reset or in module standby mode, but retains its previous value in software standby mode.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|

### 14.2.4 Compare Match Constant Register (CMCOR)

CMCOR is a 16-bit register that sets the interval up to a compare match with CMCNT.

CMCOR is initialized to H'FFFF by a power-on reset or in module standby mode, but retains its previous value in software standby mode.

|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Initial value: | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   | 1   |

## 14.3 Operation

### 14.3.1 Interval Count Operation

When an internal clock is selected with the CKS[1:0] bits in CMCSR and the STR bit in CMSTR is set to 1, CMCNT starts incrementing using the selected clock. When the values in CMCNT and CMCOR match, CMCNT is cleared to H'0000 and the CMF flag in CMCSR is set to 1. When the CMIE bit in CMCSR is set to 1 at this time, a compare match interrupt (CMI) is requested. CMCNT then starts counting up again from H'0000.

Figure 14.2 shows the operation of the compare match counter.

**Figure 14.2 Counter Operation**

### 14.3.2 CMCNT Count Timing

One of four clocks ( $P\phi/8$ ,  $P\phi/32$ ,  $P\phi/128$ , and  $P\phi/512$ ) obtained by dividing the peripheral clock ( $P\phi$ ) can be selected with the CKS[1:0] bits in CMCSR. Figure 14.3 shows the timing.

**Figure 14.3 Count Timing**

## 14.4 Interrupts

### 14.4.1 Interrupt Sources and DTC/DMAC Transfer Requests

The CMT has channels and each of them to which a different vector address is allocated has a compare match interrupt. When both the interrupt request flag (CMF) and the interrupt enable bit (CMIE) are set to 1, the corresponding interrupt request is output. When the interrupt is used to activate a CPU interrupt, the priority of channels can be changed by the interrupt controller settings. For details, see section 6, Interrupt Controller (INTC).

Clear the CMF bit to 0 by the user exception handling routine. If this operation is not carried out, another interrupt will be generated. The direct memory access controller (DMAC) can be set to be activated when a compare match interrupt is requested. In this case, an interrupt is not issued to the CPU. If the setting to activate the DMAC has not been made, an interrupt request is sent to the CPU. The CMF bit is automatically cleared to 0 when data is transferred by the DMAC.

The data transfer controller (DTC) can be activated by an interrupt request. In this case, the priority between channels is fixed. For details, refer to section 8, Data Transfer Controller (DTC).

**Table 14.2 Interrupt Sources**

| Channel | Interrupt Source | Interrupt Enable Bit | Interrupt Flag | DMAC/DTC Activation | Priority |
|---------|------------------|----------------------|----------------|---------------------|----------|
| 0       | CMIO             | CMIE                 | CMF            | Possible            | High     |
| 1       | CM11             | CMIE                 | CMF            | Possible            | Low      |

### 14.4.2 Timing of Compare Match Flag Setting

When CMCOR and CMCNT match, a compare match signal is generated at the last state in which the values match (the timing when the CMCNT value is updated to H'0000) and the CMF bit in CMCSR is set to 1. That is, after a match between CMCOR and CMCNT, the compare match signal is not generated until the next CMCNT counter clock input. Figure 14.4 shows the timing of CMF bit setting.

**Figure 14.4 Timing of CMF Setting**

### 14.4.3 Timing of Compare Match Flag Clearing

The CMF bit in CMCSR is cleared by first, reading as 1 then writing to 0. However, in the case of the DMAC being activated, the CMF bit is automatically cleared to 0 when data is transferred by the DMAC.

## 14.5 Usage Notes

### 14.5.1 Conflict between Write and Compare-Match Processes of CMCNT

When the compare match signal is generated in the T2 cycle while writing to CMCNT, clearing CMCNT has priority over writing to it. In this case, CMCNT is not written to. Figure 14.5 shows the timing to clear the CMCNT counter.

**Figure 14.5 Conflict between Write and Compare Match Processes of CMCNT**

### 14.5.2 Conflict between Word-Write and Count-Up Processes of CMCNT

Even when the count-up occurs in the T2 cycle while writing to CMCNT in words, the writing has priority over the count-up. In this case, the count-up is not performed. Figure 14.6 shows the timing to write to CMCNT in words.

**Figure 14.6 Conflict between Word-Write and Count-Up Processes of CMCNT**

### 14.5.3 Conflict between Byte-Write and Count-Up Processes of CMCNT

Even when the count-up occurs in the T2 cycle while writing to CMCNT in bytes, the writing has priority over the count-up. In this case, the count-up is not performed. The byte data on the other side, which is not written to, is also not counted and the previous contents are retained.

Figure 14.7 shows the timing when the count-up occurs in the T2 cycle while writing to CMCNTH in bytes.

**Figure 14.7 Conflict between Byte-Write and Count-Up Processes of CMCNT**

### 14.5.4 Compare Match between CMCNT and CMCOR

Do not set a same value to CMCNT and CMCOR while the count operation of CMCNT is stopped.

## Section 15 Watchdog Timer (WDT)

This LSI includes the watchdog timer (WDT), which externally outputs an overflow signal ( $\overline{\text{WDTOVF}}$ ) on overflow of the counter when the value of the counter has not been updated because of a system malfunction. The WDT can simultaneously generate an internal reset signal for the entire LSI.

The WDT is a single channel timer that counts up the clock oscillation settling period when the system leaves the temporary standby periods that occur when the clock frequency is changed. It can also be used as a general watchdog timer or interval timer.

### 15.1 Features

- Can be used to ensure the clock oscillation settling time  
The WDT is used in leaving the temporary standby periods that occur when the clock frequency is changed.
- Can switch between watchdog timer mode and interval timer mode.
- Outputs  $\overline{\text{WDTOVF}}$  signal in watchdog timer mode  
When the counter overflows in watchdog timer mode, the  $\overline{\text{WDTOVF}}$  signal is output externally. It is possible to select whether to reset the LSI internally when this happens. Either the power-on reset or manual reset signal can be selected as the internal reset type.
- Interrupt generation in interval timer mode  
An interval timer interrupt is generated when the counter overflows.
- Choice of eight counter input clocks  
Eight clocks ( $P\phi \times 1$  to  $P\phi \times 1/16384$ ) that are obtained by dividing the peripheral clock can be selected.

Figure 15.1 shows a block diagram of the WDT.

**Figure 15.1 Block Diagram of WDT**

## 15.2 Input/Output Pin

Table 15.1 shows the pin configuration of the WDT.

**Table 15.1 Pin Configuration**

| Pin Name                | Symbol | I/O    | Function                                                   |
|-------------------------|--------|--------|------------------------------------------------------------|
| Watchdog timer overflow | WDTOVF | Output | Outputs the counter overflow signal in watchdog timer mode |

## 15.3 Register Descriptions

The WDT has the following registers.

**Table 15.2 Register Configuration**

| Register Name                          | Abbreviation | R/W | Initial Value | Address    | Access Size |
|----------------------------------------|--------------|-----|---------------|------------|-------------|
| Watchdog timer counter                 | WTCNT        | R/W | H'00          | H'FFFE0002 | 16*         |
| Watchdog timer control/status register | WTCSR        | R/W | H'18          | H'FFFE0000 | 16*         |
| Watchdog reset control/status register | WRCSR        | R/W | H'1F          | H'FFFE0004 | 16*         |

Note: \* For the access size, see section 15.3.4, Notes on Register Access.

### 15.3.1 Watchdog Timer Counter (WTCNT)

WTCNT is an 8-bit readable/writable register that is incremented by cycles of the selected clock signal. When an overflow occurs, it generates a watchdog timer overflow signal ( $\overline{\text{WDTOVF}}$ ) in watchdog timer mode and an interrupt in interval timer mode.

WTCNT is initialized to H'00 by a power-on reset caused by the  $\overline{\text{RES}}$  pin or in software standby mode.

Use word access to write to WTCNT, writing H'5A in the upper byte. Use byte access to read from WTCNT.

Note: The method for writing to WTCNT differs from that for other registers to prevent erroneous writes. See section 15.3.4, Notes on Register Access, for details.

15.3.2 Watchdog Timer Control/Status Register (WTCSR)

WTCSR is an 8-bit readable/writable register composed of bits to select the clock used for the count, overflow flags, and timer enable bit.

WTCSR is initialized to H'18 by a power-on reset caused by the  $\overline{\text{RES}}$  pin, an internal reset caused by the WDT, or in software standby mode.

Use word access to write to WTCSR, writing H'A5 in the upper byte. Use byte access to read from WTCSR.

Note: The method for writing to WTCSR differs from that for other registers to prevent erroneous writes. See section 15.3.4, Notes on Register Access, for details.

|                |       |                            |     |   |   |          |     |     |
|----------------|-------|----------------------------|-----|---|---|----------|-----|-----|

### 15.3.3 Watchdog Reset Control/Status Register (WRCSR)

WRCSR is an 8-bit readable/writable register that controls output of the internal reset signal generated by watchdog timer counter (WTCNT) overflow.

WRCSR is initialized to H'1F by input of a reset signal from the  $\overline{\text{RES}}$  pin, but is not initialized by the internal reset signal generated by overflow of the WDT. WRCSR is initialized to H'1F in software standby mode.

Note: The method for writing to WRCSR differs from that for other registers to prevent erroneous writes. See section 15.3.4, Notes on Register Access, for details.

15.3.4 Notes on Register Access

The watchdog timer counter (WTCNT), watchdog timer control/status register (WTCSR), and watchdog reset control/status register (WRCSR) are more difficult to write to than other registers. The procedures for reading or writing to these registers are given below.

(1) Writing to WTCNT and WTCSR

These registers must be written by a word transfer instruction. They cannot be written by a byte or longword transfer instruction.

When writing to WTCNT, set the upper byte to H'5A and transfer the lower byte as the write data, as shown in figure 15.2. When writing to WTCSR, set the upper byte to H'A5 and transfer the lower byte as the write data. This transfer procedure writes the lower byte data to WTCNT or WTCSR.

Figure 15.2 Writing to WTCNT and WTCSR

## (2) Writing to WRCSR

WRCSR must be written by a word access to address H'FFFE0004. It cannot be written by byte transfer or longword transfer instructions.

Procedures for writing 0 to WOVF (bit 7) and for writing to RSTE (bit 6) and RSTS (bit 5) are different, as shown in figure 15.3.

To write 0 to the WOVF bit, write H'A5 to the upper byte and write the write data to the lower byte. This clears the WOVF bit to 0. The RSTE and RSTS bits are not affected. To write to the RSTE and RSTS bits, the upper byte must be H'5A and the lower byte must be the write data. The values of bits 6 and 5 of the lower byte are transferred to the RSTE and RSTS bits, respectively. The WOVF bit is not affected.

**Figure 15.3 Writing to WRCSR**

## (3) Reading from WTCNT, WTCSR, and WRCSR

WTCNT, WTCSR, and WRCSR are read in a method similar to other registers. WTCSR is allocated to address H'FFFE0000, WTCNT to address H'FFFE0002, and WRCSR to address H'FFFE0004. Byte transfer instructions must be used for reading from these registers.

## 15.4 WDT Usage

### 15.4.1 Canceling Software Standby Mode

The WDT can be used to cancel software standby mode with an interrupt such as an NMI interrupt. The procedure is described below. (The WDT does not operate when resets are used for canceling, so keep the  $\overline{\text{RES}}$  or  $\overline{\text{MRES}}$  pin low until clock oscillation settles.)

1. Before making a transition to software standby mode, always clear the TME bit in WTCSR to 0. When the TME bit is 1, an erroneous reset or interval timer interrupt may be generated when the count overflows.
2. Set the type of count clock used in the CKS[2:0] bits in WTCSR and the initial value of the counter in WTCNT. These values should ensure that the time till count overflow is longer than the clock oscillation settling time.
3. After setting the STBY bit of the standby control register (STBCR: see section 30, Power-Down Modes) to 1, the execution of a SLEEP instruction puts the system in software standby mode and clock operation then stops.
4. The WDT starts counting by detecting the edge change of the NMI signal.
5. When the WDT count overflows, the CPG starts supplying the clock and this LSI resumes operation. The WOVF flag in WRCSR is not set when this happens.

### 15.4.2 Using Watchdog Timer Mode

1. Set the WT/IT $\overline{\text{bit}}$  in WTCSR to 1, the type of count clock in the CKS[2:0] bits in WTCSR, whether this LSI is to be reset internally or not in the RSTE bit in WRCSR, the reset type if it is generated in the RSTS bit in WRCSR, and the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in watchdog timer mode.
3. While operating in watchdog timer mode, rewrite the counter periodically to H'00 to prevent the counter from overflowing.
4. When the counter overflows, the WDT sets the WOVF flag in WRCSR to 1, and the  $\overline{\text{WDTOVF}}$  signal is output externally (figure 15.4). The  $\overline{\text{WDTOVF}}$  signal can be used to reset the system. The  $\overline{\text{WDTOVF}}$  signal is output for  $64 \times P\phi$  clock cycles.
5. If the RSTE bit in WRCSR is set to 1, a signal to reset the inside of this LSI can be generated simultaneously with the  $\overline{\text{WDTOVF}}$  signal. Either power-on reset or manual reset can be selected for this interrupt by the RSTS bit in WRCSR. The internal reset signal is output for  $128 \times P\phi$  clock cycles.

6. When a WDT overflow reset is generated simultaneously with a reset input on the  $\overline{\text{RES}}$  pin, the  $\overline{\text{RES}}$  pin reset takes priority, and the WOVF bit in WRCR is cleared to 0.
7. Since WTCR is initialized by an internal reset caused by the WDT, the TME bit in WTCR is cleared to 0. This makes the counter stop (be initialized). To use the WDT in watchdog timer mode again, after clearing the WOVF flag in WRCR, set watchdog timer mode again.

**Figure 15.4 Operation in Watchdog Timer Mode**

### 15.4.3 Using Interval Timer Mode

When operating in interval timer mode, interval timer interrupts are generated at every overflow of the counter. This enables interrupts to be generated at set periods.

1. Clear the  $\overline{WT/IT}$  bit in WTCSR to 0, set the type of count clock in the CKS[2:0] bits in WTCSR, and set the initial value of the counter in WTCNT.
2. Set the TME bit in WTCSR to 1 to start the count in interval timer mode.
3. When the counter overflows, the WDT sets the IOVF bit in WTCSR to 1 and an interval timer interrupt request is sent to the INTC. The counter then resumes counting.

**Figure 15.5 Operation in Interval Timer Mode**

## 15.5 Interrupt Sources

The watchdog timer has the interval timer interrupt (ITI).

Table 15.3 gives details on the interrupt source.

The interval timer interrupt (ITI) is generated when the interval timer overflow flag (IOVF) in the watchdog timer control/status register (WTCSR) is set to 1.

Clearing the interrupt flag bit to 0 cancels the interrupt request.

**Table 15.3 Interrupt Source**

| Abbreviation | Interrupt Source         | Interrupt Enable Bit | Interrupt Flag                      |
|--------------|--------------------------|----------------------|-------------------------------------|
| ITI          | Interval timer interrupt | —                    | Interval timer overflow flag (IOVF) |

## 15.6 Usage Notes

Pay attention to the following points when using the WDT in either the interval timer or watchdog timer mode.

### 15.6.1 Timer Variation

After timer operation has started, the period from the power-on reset point to the first count up timing of WTCNT varies depending on the time period that is set by the TME bit of WTCSR. The shortest such time period is thus one cycle of the peripheral clock, P $\phi$ , while the longest is the result of frequency division according to the value in the CKS[2:0] bits. The timing of subsequent incrementation is in accord with the selected frequency division ratio. Accordingly, this time difference is referred to as timer variation.

This also applies to the timing of the first incrementation after WTCNT has been written to during timer operation.

### 15.6.2 Prohibition against Setting H'FF to WTCNT

When the value in WTCNT reaches H'FF, the WDT assumes that an overflow has occurred. Accordingly, when H'FF is set in WTCNT, an interval timer interrupt or WDT reset will occur immediately, regardless of the current clock selection by the CKS[2:0] bits.

### 15.6.3 Interval Timer Overflow Flag

As long as the value of WTCNT is H'FF, clearing the IOVF flag in WTCSR is not possible. Clear the flag when the value of WTCNT becomes H'00 or after writing a value other than H'FF to WTCNT.

### 15.6.4 System Reset by $\overline{\text{WDTOVF}}$ Signal

If the  $\overline{\text{WDTOVF}}$  signal is input to the  $\overline{\text{RES}}$  pin of this LSI, this LSI cannot be initialized correctly.

Avoid input of the  $\overline{\text{WDTOVF}}$  signal to the  $\overline{\text{RES}}$  pin of this LSI through glue logic circuits. To reset the entire system with the  $\overline{\text{WDTOVF}}$  signal, use the circuit shown in figure 15.6.

**Figure 15.6 Example of System Reset Circuit Using  $\overline{\text{WDTOVF}}$  Signal**

### 15.6.5 Manual Reset in Watchdog Timer Mode

When a manual reset occurs in watchdog timer mode, the internal bus (I bus) cycle is continued. If a manual reset occurs while the bus is released or during DMAC burst transfer, manual reset exception handling will be pended until the CPU acquires the bus mastership.

### 15.6.6 Connection of the $\overline{\text{WDTOVF}}$ Pin

When the  $\overline{\text{WDTOVF}}$  pin is not in use, leave the pin open-circuit. If pulling down is required, the value of the resistor must be at least 1 M $\Omega$ .

## Section 16 Serial Communication Interface (SCI)

This LSI has four channels of independent serial communication interface (SCI). The SCI can handle both asynchronous and clock synchronous serial communication. In asynchronous serial communication mode, serial data communication can be carried out with standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communications Interface Adapter (ACIA). A function is also provided for serial communication between processors (multiprocessor communication function).

### 16.1 Features

- Choice of asynchronous or clock synchronous serial communication mode
- Asynchronous mode:
  - Serial data communication is performed by start-stop in character units. The SCIF can communicate with a universal asynchronous receiver/transmitter (UART), an asynchronous communications interface adapter (ACIA), or any other communications chip that employs a standard asynchronous serial system. There are twelve selectable serial data communication formats.
  - Data length: 7 or 8 bits
  - Stop bit length: 1 or 2 bits
  - Parity: Even, odd, or none
  - Multiprocessor communications
  - Receive error detection: Parity, overrun, and framing errors
  - Break detection: Break is detected by reading the RXD pin level directly when a framing error occurs.
- Clock synchronous mode:
  - Serial data communication is synchronized with a clock signal. The SCIF can communicate with other chips having a clock synchronous communication function.
  - Data length: 8 bits
  - Receive error detection: Overrun errors
- Full duplex communication: The transmitting and receiving sections are independent, so the SCI can transmit and receive simultaneously. Both sections use double buffering, so high-speed continuous data transfer is possible in both the transmit and receive directions.
- On-chip baud rate generator with selectable bit rates
- Internal or external transmit/receive clock source: From either baud rate generator (internal clock) or SCK pin (external clock)
- Choice of LSB-first or MSB-first data transfer (except for 7-bit data in asynchronous mode)

- Four types of interrupts: There are four interrupt sources, transmit-data-empty, transmit end, receive-data-full, and receive error interrupts, and each interrupt can be requested independently. The data transfer controller (DTC) can be activated by the transmit-data-empty interrupt or receive-data-full interrupt to transfer data.
- Module standby mode can be set

Figure 16.1 shows a block diagram of the SCI.

**Figure 16.1 Block Diagram of SCI**

## 16.2 Input/Output Pins

The SCI has the serial pins summarized in table 16.1.

**Table 16.1 Pin Configuration**

| Channel | Pin Name* | I/O    | Function                  |
|---------|-----------|--------|---------------------------|
| 0       | SCK0      | I/O    | SCI0 clock input/output   |
|         | RXD0      | Input  | SCI0 receive data input   |
|         | TXD0      | Output | SCI0 transmit data output |
| 1       | SCK1      | I/O    | SCI1 clock input/output   |
|         | RXD1      | Input  | SCI1 receive data input   |
|         | TXD1      | Output | SCI1 transmit data output |
| 2       | SCK2      | I/O    | SCI2 clock input/output   |
|         | RXD2      | Input  | SCI2 receive data input   |
|         | TXD2      | Output | SCI2 transmit data output |
| 4       | SCK4      | I/O    | SCI4 clock input/output   |
|         | RXD4      | Input  | SCI4 receive data input   |
|         | TXD4      | Output | SCI4 transmit data output |

Note: \* Pin names SCK, RXD, and TXD are used in the description for all channels, omitting the channel designation.

## 16.3 Register Descriptions

The SCI has the following registers for each channel. For details on register addresses and register states during each processing, refer to section 32, List of Registers.

**Table 16.2 Register Configuration**

| Channel | Register Name                       | Abbrevia-<br>tion | R/W | Initial<br>Value | Address    | Access<br>Size |
|---------|-------------------------------------|-------------------|-----|------------------|------------|----------------|
| 0       | Serial mode register_0              | SCSMR_0           | R/W | H'00             | H'FFFF8000 | 8              |
|         | Bit rate register_0                 | SCBRR_0           | R/W | H'FF             | H'FFFF8002 | 8              |
|         | Serial control register_0           | SCSCR_0           | R/W | H'00             | H'FFFF8004 | 8              |
|         | Transmit data register_0            | SCTDR_0           | R/W | —                | H'FFFF8006 | 8              |
|         | Serial status register_0            | SCSSR_0           | R/W | H'84             | H'FFFF8008 | 8              |
|         | Receive data register_0             | SCRDR_0           | R   | —                | H'FFFF800A | 8              |
|         | Serial direction control register_0 | SCSDCR_0          | R/W | H'F2             | H'FFFF800C | 8              |
|         | Serial port register_0              | SCSPTR_0          | R/W | H'0x             | H'FFFF800E | 8              |
| 1       | Serial mode register_1              | SCSMR_1           | R/W | H'00             | H'FFFF8800 | 8              |
|         | Bit rate register_1                 | SCBRR_1           | R/W | H'FF             | H'FFFF8802 | 8              |
|         | Serial control register_1           | SCSCR_1           | R/W | H'00             | H'FFFF8804 | 8              |
|         | Transmit data register_1            | SCTDR_1           | R/W | —                | H'FFFF8806 | 8              |
|         | Serial status register_1            | SCSSR_1           | R/W | H'84             | H'FFFF8808 | 8              |
|         | Receive data register_1             | SCRDR_1           | R   | —                | H'FFFF880A | 8              |
|         | Serial direction control register_1 | SCSDCR_1          | R/W | H'F2             | H'FFFF880C | 8              |
|         | Serial port register_1              | SCSPTR_1          | R/W | H'0x             | H'FFFF880E | 8              |
| 2       | Serial mode register_2              | SCSMR_2           | R/W | H'00             | H'FFFF9000 | 8              |
|         | Bit rate register_2                 | SCBRR_2           | R/W | H'FF             | H'FFFF9002 | 8              |
|         | Serial control register_2           | SCSCR_2           | R/W | H'00             | H'FFFF9004 | 8              |
|         | Transmit data register_2            | SCTDR_2           | R/W | —                | H'FFFF9006 | 8              |
|         | Serial status register_2            | SCSSR_2           | R/W | H'84             | H'FFFF9008 | 8              |
|         | Receive data register_2             | SCRDR_2           | R   | —                | H'FFFF900A | 8              |
|         | Serial direction control register_2 | SCSDCR_2          | R/W | H'F2             | H'FFFF900C | 8              |
|         | Serial port register_2              | SCSPTR_2          | R/W | H'0x             | H'FFFF900E | 8              |

| Channel | Register Name                          | Abbrevia-<br>tion | R/W | Initial<br>Value | Address   | Access<br>Size |
|---------|----------------------------------------|-------------------|-----|------------------|-----------|----------------|
| 4       | Serial mode register_4                 | SCSMR_4           | R/W | H'00             | H'FFFA000 | 8              |
|         | Bit rate register_4                    | SCBRR_4           | R/W | H'FF             | H'FFFA002 | 8              |
|         | Serial control register_4              | SCSCR_4           | R/W | H'00             | H'FFFA004 | 8              |
|         | Transmit data register_4               | SCTDR_4           | R/W | —                | H'FFFA006 | 8              |
|         | Serial status register_4               | SCSSR_4           | R/W | H'84             | H'FFFA008 | 8              |
|         | Receive data register_4                | SCRDR_4           | R   | —                | H'FFFA00A | 8              |
|         | Serial direction control<br>register_4 | SCSDCR_4          | R/W | H'F2             | H'FFFA00C | 8              |
|         | Serial port register_4                 | SCSPTR_4          | R/W | H'0x             | H'FFFA00E | 8              |

### 16.3.1 Receive Shift Register (SCRSR)

SCRSR receives serial data. Data input at the RXD pin is loaded into SCRSR in the order received, LSB (bit 0) first, converting the data to parallel form. When one byte has been received, it is automatically transferred to SCRDR. The CPU cannot read or write to SCRSR directly.

### 16.3.2 Receive Data Register (SCRDR)

SCRDR is a register that stores serial receive data. After receiving one byte of serial data, the SCI transfers the received data from the receive shift register (SCRSR) into SCRDR for storage and completes operation. After that, SCRSR is ready to receive data.

Since SCRSR and SCRDR work as a double buffer in this way, data can be received continuously.

SCRDR is a read-only register and cannot be written to by the CPU.

### 16.3.3 Transmit Shift Register (SCTSR)

SCTSR transmits serial data. The SCI loads transmit data from the transmit data register (SCTDR) into SCTSR, then transmits the data serially from the TXD pin, LSB (bit 0) first. After transmitting one data byte, the SCI automatically loads the next transmit data from SCTDR into SCTSR and starts transmitting again. If the TDRE flag in the serial status register (SCSSR) is set to 1, the SCI does not transfer data from SCTDR to SCTSR. The CPU cannot read or write to SCTSR directly.

|                |   |   |   |   |   |   |   |   |
|----------------|---|---|---|---|---|---|---|---|
| Bit:           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|                |   |   |   |   |   |   |   |   |
| Initial value: | - | - | - | - | - | - | - | - |
| R/W:           | - | - | - | - | - | - | - | - |

### 16.3.4 Transmit Data Register (SCTDR)

SCTDR is an 8-bit register that stores data for serial transmission. When the SCI detects that the transmit shift register (SCTSR) is empty, it moves transmit data written in the SCTDR into SCTSR and starts serial transmission. If the next transmit data has been written to SCTDR during serial transmission from SCTSR, the SCI can transmit data continuously. SCTDR can always be written or read to by the CPU.

|                |     |     |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|-----|-----|
| Bit:           | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|                |     |     |     |     |     |     |     |     |
| Initial value: | -   | -   | -   | -   | -   | -   | -   | -   |
| R/W:           | R/W | R/W | R/W | R/W | R/W | R/W | R/W | R/W |

### 16.3.5 Serial Mode Register (SCSMR)

SCSMR is an 8-bit register that specifies the SCI serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to SCSMR.

|                |     |     |     |     |      |     |          |     |
|----------------|-----|-----|-----|-----|------|-----|----------|-----|
| Bit:           | 7   | 6   | 5   | 4   | 3    | 2   | 1        | 0   |
|                | C/Ā | CHR | PE  | O/Ē | STOP | MP  | CKS[1:0] |     |

### 16.3.6 Serial Control Register (SCSCR)

SCSCR is an 8-bit register that enables or disables SCI transmission/reception and interrupt requests and selects the transmit/receive clock source. The CPU can always read and write to SCSCR.

Clearing RE to 0 does not affect the receive flags (RDRF, FER, PER, and ORER). These flags retain their previous values.</p> <p>2. Serial reception starts when a start bit is detected in asynchronous mode, or synchronous clock input is detected in clock synchronous mode. Select the receive format in SCSMR before setting RE to 1.</p> |
| 3   | MPIE     | 0             | R/W | <p>Multiprocessor Interrupt Enable (only when MP = 1 in SCSMR in asynchronous mode)</p> <p>When this bit is set to 1, receive data in which the multiprocessor bit is 0 is skipped and setting of the RDRF, FER, and ORER status flags in SCSSR is prohibited. On receiving data in which the multiprocessor bit is 1, this bit is automatically cleared to 0 and normal receiving operation is resumed. For details, refer to section 16.4.4, Multiprocessor Communication Function.</p>                              |

### 16.3.7 Serial Status Register (SCSSR)

SCSSR is an 8-bit register that contains status flags to indicate the SCI operating state.

The CPU can always read and write to SCSSR, but cannot write 1 to status flags TDRE, RDRF, ORER, PER, and FER. These flags can be cleared to 0 only after 1 is read from the flags. The TEND flag is a read-only bit and cannot be modified.

|                |        |        |        |        |        |      |     |      |
|----------------|--------|--------|--------|--------|--------|------|-----|------|
| Bit:           | 7      | 6      | 5      | 4      | 3      | 2    | 1   | 0    |
|                | TDRE   | RDRF   | ORER   | FER    | PER    | TEND | MPB | MPBT |
| Initial value: | 1      | 0      | 0      | 0      | 0      | 1    | 0   | 0    |
| R/W:           | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R/(W)* | R    | R   | R/W  |

Note: \* Writing 0 to this bit after reading it as 1 clears the flag and is the only allowed way.

The ORER flag is not affected and retains its previous value when the RE bit in SCSCR is cleared to 0.</p> <p>2. The receive data prior to the overrun error is retained in SCRDR, and the data received subsequently is lost. Subsequent serial reception cannot be continued while the ORER flag is set to 1.</p> |
