## **GENERAL DESCRIPTION**

The DS32501 (single), DS32502 (dual), DS32503 (triple), and DS32504 (quad) line interface units (LIUs) are highly integrated, low-power, feature-rich LIUs for DS3, E3, and STS-1 applications. Each LIU port in these devices has independent receive and transmit paths, a jitter attenuator, a full-featured pattern generator and detector, performance monitoring counters, and a complete set of loopbacks. An on-chip clock adapter generates all line-rate clocks from a single input clock. Ports are independently software configurable for DS3, E3, and STS-1 and can be individually powered down. Control interface options include 8-bit parallel, SPI, and hardware mode.

## **APPLICATIONS**

## **ORDERING INFORMATION**

*Note: Add "+" for the lead-free package option.*  \**Future product—contact factory for availability.*

#### *Functional Diagram appears in Section [3](#page-7-0) (see [Figure 3-1](#page-7-0)).*

## **FEATURES**

- **Pin-Compatible Family of Products**
- **Each Port Independently Configurable**
- **Receive Clock and Data Recovery for Up to 457 meters (1500 feet) of 75**Ω **Coaxial Cable**
- **Standards-Compliant Transmit Waveshaping**
- **Uses 1:1 Transformers on Both Tx and Rx**
- **Three Control Interface Options: 8/16-Bit Parallel, SPI, and Hardware Mode**
- **Jitter Attenuators (One Per Port) Can be Placed in the Receive Path or the Transmit Path**
- **Jitter Attenuators Have Provisionable Buffer Depth: 16, 32, 64, or 128 Bits**
- **Built-In Clock Adapter Generates All Line-Rate Clocks from a Single Input Clock (DS3, E3, STS-1, 12.8MHz, 19.44MHz, 38.88MHz, 77.76MHz)**
- **Per-Port Programmable Internal Line Termination Requiring Only External Transformers**
- **High-Impedance Tx and Rx, Even When**  V<sub>DD</sub> = 0, Enables Hot-Swappable, 1:1, and 1+1 **Board Redundancy Without Relays**
- **Per-Port BERT for PRBS and Repetitive Pattern Generation and Detection**
- **Tx and Rx Open- and Short-Detection Circuitry**
- **Transmit Driver Monitor Circuitry**
- **Receive Loss-of-Signal (LOS) Monitoring Compliant with ANSI T1.231 and ITU G.775**
- **Automatic Data Squelching on Receive LOS**
- **Large Line Code Performance Monitoring Counters for Accumulation Intervals Up to 1s**
- **Local and Remote Loopbacks**
- **Transmit Common Clock Option**
- **Power-Down Capability for Unused Ports**
- **Low-Power 1.8V/3.3V Operation (5V Tolerant I/O)**
- **Industrial Temperature Range: -40°C to +85**°**C**
- **Small Package: (13mm)<sup>2</sup> 144-Pin TE-CSBGA**
- **IEEE 1149.1 JTAG Support**

 *Note: Some revisions of this device may incorporate deviations from published specifications known as errata. Multiple revisions of any device*  may be simultaneously available through various sales channels. For information about device errata, click here: **www.maxim-ic.com/errata**.

## <span id="page-6-0"></span>**2. STANDARDS COMPLIANCE**

## **Table 2-1. Applicable Telecommunications Standards**

## <span id="page-7-0"></span>**3. DETAILED DESCRIPTION**

The DS32501 (single), DS32502 (dual), DS3203 (triple), and DS32504 (quad) LIUs perform the functions necessary for interfacing at the physical layer to DS3, E3, or STS-1 lines. Each LIU has independent receive and transmit paths and a built-in jitter attenuator. The receiver performs clock and data recovery from a B3ZS- or HDB3-coded alternate mark inversion (AMI) signal and monitors for loss of the incoming signal. The receiver optionally performs B3ZS/HDB3 decoding and outputs the recovered data in either binary (NRZ) or digital bipolar format. The transmitter accepts data in either binary (NRZ) or digital bipolar format, optionally performs B3ZS/HDB3 encoding, and drives standard pulse-shape waveforms onto 75Ω coaxial cable. Both transmitter and receiver are high impedance when  $V_{DD}$  is out of spec to enable hot-swappable 1:1 and 1+1 board redundancy without relays. The jitter attenuator can be mapped into the receiver data path, mapped into the transmitter data path, or can be disabled. An on-chip clock adapter generates all line-rate clocks from a single input clock. Control interface options include 8- or 16-bit parallel, SPI, and hardware mode. The DS3250x LIUs conform to the telecommunications standards listed in [Table 2-1.](#page-6-0) The external components required for proper operation are shown in [Figure 3-2](#page-7-0) and [Figure 3-3](#page-8-0).

PRELIMINARY

**Shorthand Notations.** The notation "DS3250x" throughout this data sheet refers to either the DS32501, DS32502, DS3203, or DS32504. This data sheet is the specification for all four devices. The LIUs on the DS3250x devices are identical. For brevity, this document uses the pin name and register name shorthand "NAMEn," where "n" stands in place of the LIU port number. For example, on the DS32504, TCLKn is shorthand notation for pins TCLK1, TCLK2, TCLK3, and TCLK4 on LIU ports 1, 2, 3 and 4, respectively. This document also uses generic pin and register names such as TCLK (without a number suffix) when describing LIU operation. When working with a specific LIU on the DS3250x devices, generic names like TCLK should be converted to actual pin names, such as TCLK1.

## <span id="page-10-0"></span>**5. BLOCK DIAGRAM**

## **Figure 5-1. Block Diagram**

## <span id="page-11-0"></span>**6. FEATURE DETAILS**

#### **6.1 Global Features**

- Three interface modes: hardware, 8-/16-bit parallel bus, and SPI serial bus
- Independent per port operation (e.g., line rate, jitter attenuator placement, or loopback type)
- Clock, data, and control signals can be inverted to allow a glueless interface to other devices
- Manual or automatic one-second update of performance monitoring counters
- Each port can be put into a low-power standby mode when not being used
- Requires only a single reference clock for all three LIU data rates using internal clock rate adapter
- Jitter attenuators can be used in either transmit or receive path
- Detection of loss of transmit clock
- Two programmable I/O pins per port
- Optional global write mode configures all LIUs at the same time
- Glueless interface to neighboring framer and mapper components

#### **6.2 Receiver Features**

- AGC/equalizer block handles from 0 to 22dB of cable loss
- Programmable internal termination resistor
- Loss-of-lock (LOL) PLL status indication
- Interfaces directly to a DSX monitor signal (~20dB flat loss) using built-in preamp
- Digital and analog loss-of-signal (LOS) detectors (compliant with ANSI T1.231 and ITU-T G.775)
- Software programmable B3ZS/HDB3 or AMI decoding
- Detection and accumulation of bipolar violations (BPV), code violations (CV), and excessive zeroes occurrences (EXZ)
- Detection of receipt of B3ZS/HDB3 codewords
- Binary or bipolar framer interface
- On-board programmable PRBS detector
- Per-channel power-down control

### **6.3 Transmitter Features**

- Standards-compliant waveshaping
- Programmable waveshaping
- Programmable internal termination resistor
- Binary or bipolar framer interface
- Gapped clock capable up to 78MHz with jitter attenuator in transmit path
- Wide  $50 \pm 20\%$  transmit clock duty cycle
- Transmit common clock option
- Software programmable B3ZS/HDB3 or AMI decoding
- Programmable insertion of bipolar violations (BPV), code violations (CV), and excessive zeros (EXZ)
- AIS generator: unframed all ones, framed DS3 AIS, and STS-1 AIS-L
- Line build-out (LBO) control
- High-impedance line driver output mode to support protection switching applications
- Per-channel power-down control
- Output driver monitor

#### **6.4 Jitter Attenuator Features**

- One jitter attenuator per port
- Fully integrated, requires no external components
- Meets all applicable ANSI, ITU, ETSI, and Telcordia jitter transfer and output jitter requirements
- Can be placed in the transmit path, receive path, or disabled
- Programmable FIFO depth: 16, 32, 64, or 128 bits
- Overflow and underflow status indications

## <span id="page-12-0"></span>**6.5 Bit Error Rate Tester (BERT) Features**

- One BERT per port
- Software programmable for insertion toward the transmit line interface or the receive system interface
- Generates and detects pseudorandom patterns of length  $2<sup>n</sup>$  1 (n = 1-32) and repetitive patterns from 1 to 32 bits in length
- Large 24-bit error counter and 32-bit bit counter allows testing to proceed for long periods without host intervention
- Errors can be inserted in the generated BERT patterns for diagnostic purposes (single bit errors or specific biterror rates)
- Pattern synchronization even in the presence of  $10^{-3}$  bit error rate

## **6.6 Clock Adapter Features**

- Creates DS3, E3, STS-1, and/or telecom bus clocks from single input reference clock
- Input reference clock can be DS3, E3, STS-1, 12.8MHz, 19.44MHz, 38.88MHz, or 77.76MHz
- Use of common system timing frequencies such as 19.44MHz eliminates the need for any local oscillators, reduces cost and board space
- Very small jitter gain and intrinsic jitter generation
- Derived clocks can be output for external system use
- Transmit signals using CLAD clocks meet Telcordia (DS3) and ITU (E3) jitter and wander requirements

### **6.7 Parallel Microprocessor Interface Features**

- Multiplexed or nonmultiplexed 8- or 16-bit interface
- Configurable for Intel mode  $(\overline{CS}, \overline{WR}, \overline{RD})$  or Motorola mode  $(\overline{CS}, \overline{DS}, \overline{RW})$  $(\overline{CS}, \overline{DS}, \overline{RW})$  $(\overline{CS}, \overline{DS}, \overline{RW})$

## **6.8 SPI Serial Microprocessor Interface Features**

- Operation up to 10Mbps
- Burst mode for multibyte read and write accesses
- Programmable clock polarity and phase
- Half-duplex operation gives option to tie SDI and SDO together externally to reduce wire count

## **6.9 Miscellaneous Features**

- Global reset input pin
- Global interrupt output pin
- Two programmable I/O pins per port

### **6.10 Test Features**

- 5-pin JTAG port
- All functional pins are in-out pins in JTAG mode
- Standard JTAG instructions: SAMPLE/PRELOAD, BYPASS, EXTEST, CLAMP, HIGHZ, IDCODE
- $HIZ$  pin to force all digital output and I/O pins into a high-impedance state
- **[TEST](#page-17-0)** pin for manufacturing test modes

### **6.11 Loopback Features**

- Analog local loopback—ALB (transmit line output to receive line input)
- Diagnostic local loopback—DLB (transmit framer interface to receive framer interface)
- Line loopback—LLB (receive clock and data recover to transmit waveshaping)
- Optional AIS generation on the line side of the loopback during diagnostic loopback

## <span id="page-13-0"></span>**7. CONTROL INTERFACE MODES**

The DS3250x devices can be controlled by hardware interface or by microprocessor interface.

When the hardware interface is enabled [\(IFSEL](#page-17-0) =  $00X$ ), device configuration can be controlled by input pins, while device status can be sensed on output pins. In this mode pins [TOEn,](#page-18-0) [RMON](#page-18-0), [TAIS](#page-17-0), [TLBO](#page-18-0), [TBIN,](#page-17-0) [TCLKI,](#page-17-0) [TPD](#page-18-0), [RBIN](#page-18-0), [RCLKI](#page-18-0), [RPD,](#page-18-0) [LMn\[1:0\]](#page-17-0), [JAS\[1:0\]](#page-18-0), [JAD\[1:0\]](#page-18-0), and [LBn\[1:0\]](#page-19-0) are used to control the device and status can be sensed on [RLOSn](#page-18-0) pin.

The microprocessor interface (8-bit parallel, 16-bit parallel, or SPI) provides access to features, configuration options, and device status information that the hardware interface does not support. The microprocessor interface is enabled and configured by the [IFSEL](#page-17-0) pins. When IFSEL = 01X, the SPI serial interface is enabled. When IFSEL = 10X, the 8-bit parallel interface is enabled. When IFSEL = 11X, the 16-bit parallel interface is enabled. For both the 8- and 16-bit parallel interfaces, IFSEL[0] = 0 specifies an Intel-style bus  $(\overline{CS},\overline{RD})$  $(\overline{CS},\overline{RD})$  $(\overline{CS},\overline{RD})$  $(\overline{CS},\overline{RD})$  $(\overline{CS},\overline{RD})$ , and  $\overline{WR}$  $\overline{WR}$  $\overline{WR}$  control signals) while IFSEL[0] = 1 specifies a Motorola-style bus  $\overline{\text{CS}}$  $\overline{\text{CS}}$  $\overline{\text{CS}}$ , [R/W,](#page-19-0) and  $\overline{\text{DS}}$  $\overline{\text{DS}}$  $\overline{\text{DS}}$  control signals). Through the microprocessor interface an external microprocessor can access a set of internal configuration and status registers inside the device. Pins that are not used by the selected microprocessor interface type but are used in other microprocessor interface modes are disabled (inputs are ignored and considered to be low and can be left floating or wired low or high; outputs are placed in a high-impedance state and can be left unconnected or wired low or high). When no microprocessor interface is selected (IFSEL = 00X) all microprocessor interface inputs are ignored, and all microprocessor interface outputs are put in a high-impedance state.

## <span id="page-14-0"></span>**8. PIN DESCRIPTIONS**

**Note:** All digital pins are I/O pins in JTAG mode. This feature is to increase the effectiveness of board level ATPG patterns to isolate interconnect failures.

### **8.1 Short Pin Descriptions**

*n = port number (1–4 for DS32504, 1–3 for DS32503, 1–2 for DS32502, 1 for DS32501); I = input; Ipu = input with internal pullup resistor; Ipd = input with internal pulldown resistor; Ia = analog input; I/O = bidirectional in/out; I/Opd = bidirectional in/out with internal pulldown resistor; O = output; Oz = high-impedance output (needs an external pullup or pulldown resistor to keep the node from floating); Oa = analog output (high impedance); P = power supply or ground. All unused input pins without pullup should be tied low.* 

**Note:** All internal pullup resistors are 50kΩ tied to approximately 2.2VDC. See Section [13](#page-107-0) for pin assignments.

#### **Table 8-1. Short Pin Descriptions**

## <span id="page-16-0"></span>**8.2 Detailed Pin Descriptions**

*n = port number (1–4 for DS32504, 1–3 for DS32503, 1–2 for DS32502, 1 for DS32501); I = input; Ipu = input with internal pullup resistor; Ipd = input with internal pulldown resistor; Ia = analog input; I/O = bidirectional in/out; I/Opd = bidirectional in/out with internal pulldown resistor; O = output; Oz = high-impedance output (needs an external pullup or pulldown resistor to keep the node from floating); Oa = analog output (high impedance); P= power supply or ground. All unused input pins without pullup should be tied low.*

**Note:** All internal pullup resistors are 50kΩ tied to 2.2VDC.

## **Table 8-10. Power-Supply Pin Descriptions**

## **Table 8-11. Manufacturing Test Pin Descriptions**

## <span id="page-22-0"></span>**9. FUNCTIONAL DESCRIPTION**

## **9.1 LIU Mode**

Each port is independently configurable for DS3, E3 or STS-1 operation. When the hardware interface is enabled ([IFSEL](#page-17-0) = 00X), the [LMn\[1:0\]](#page-17-0) pins specify the LIU mode. When a microprocessor interface is enabled [\(IFSEL](#page-17-0)  $\neq$  00X) the [PORT.CR2:](#page-61-0)LM[1:0] control bits specify the LIU mode.

### **9.2 Transmitter**

#### **9.2.1 Transmit Clock**

If the jitter attenuator is not enabled in the transmit path, the signal on [TCLK](#page-16-0) is the transmit line clock and must be transmission quality (i.e., ±20ppm frequency accuracy and low jitter). If the jitter attenuator is enabled in the transmit path, the signal on [TCLK](#page-16-0) can be jittery and/or periodically gapped, but must still have an average frequency within ±20ppm of the nominal line rate. When enabled in the transmit path, the jitter attenuator generates the transmit line clock. See Section [9.4](#page-34-0) for more information about the jitter attenuator.

The polarity of [TCLK](#page-16-0) can be inverted to support glueless interfacing to a variety of neighboring components. Normally data is sampled on the [TPOS/TDAT](#page-16-0) and [TNEG](#page-16-0) pins on the rising edge of [TCLK.](#page-16-0) To sample these pins on the falling edge of [TCLK](#page-16-0), pull the [TCLKI](#page-17-0) (hardware interface mode) pin high or set the [PORT.INV](#page-63-0):TCLKI (microprocessor interface mode) configuration bit.

#### **9.2.1.1 Transmit Common Clock Mode**

In microprocessor interface mode the [PORT.CR2](#page-61-0):TCC register bit specifies whether the transmit clock for port n comes from [TCLKn](#page-16-0) or TCLK1. In designs where the transmit paths of all ports can be clocked synchronously with one another, common transmit clocking reduces wiring complexity between the LIU and the neighboring framer or mapper component.

#### **9.2.2 Framer Interface Format and the B3ZS/HDB3 Encoder**

Data to be transmitted can be input in either bipolar or binary format.

#### **9.2.2.1 Bipolar Interface Format**

To select the bipolar interface format, pull the [TBIN](#page-17-0) (hardware interface mode) pin low or clear the [PORT.CR2](#page-61-0):TBIN (microprocessor interface mode) configuration bit. In bipolar format, the B3ZS/HDB3 encoder is disabled and the data to be transmitted is sampled on the [TPOS](#page-16-0) and [TNEG](#page-16-0) pins. Positive-polarity pulses are indicated by [TPOS](#page-16-0) = 1, while negative-polarity pulses are indicated by [TNEG](#page-16-0) = 1. If [TPOS](#page-16-0) and [TNEG](#page-16-0) are high at the same time the transmitter generates an AMI pulse that is the opposite state of the pulse previously transmitted.

#### **9.2.2.2 Binary Interface Format**

To select the binary interface format, pull the [TBIN](#page-17-0) pin high (hardware interface mode for all ports) or set the [PORT.CR2](#page-61-0):TBIN configuration bit (microprocessor interface mode for each port). In binary format, the B3ZS/HBD3 encoder is enabled, and the NRZ data to be transmitted is sampled on the [TDAT](#page-16-0) pin. The [TNEG](#page-16-0) pin is ignored in binary interface mode and should be wired low. In DS3 and STS-1 modes, B3ZS encoding is performed. In these modes whenever three consecutive zeros are found in the transmit data stream they are replaced with a B3ZS codeword. In E3 mode HDB3 encoding is performed. In this mode, whenever four consecutive zeros are found in the transmit data stream they are replaced with an HDB3 codeword. In all three modes, the B3ZS or HDB3 codeword is constructed such that the last bit is a BPV with the opposite polarity of the most recently transmitted BPV.

#### <span id="page-23-0"></span>**9.2.3 Error Insertion**

Bipolar violation (BPV) errors and excessive zeros (EXZ) errors can be inserted into the transmit data stream using the transmit manual error insert (TMEI) logic (see Section [9.7.5\)](#page-42-0). Configuration bit [LINE.TCR](#page-77-0):BPVI enables the insertion of bipolar violations, while [LINE.TCR:](#page-77-0)EXZI enables the insertion of excessive zero events. **Note:** BPV errors and EXZ errors can only be inserted in the binary interface format.

PRELIMINARY

If the transmitter is configured for binary interface format (Section [9.2.2.2](#page-22-0)) and BPVI = 1 then when the configured manual error insert control goes from 0 to 1 the transmitter waits for the next occurrence of two consecutive 1s where the polarity of the first 1 is opposite the polarity of the BPV in the last B3ZS/HDB3 codeword. The first 1 is transmitted according to the normal AMI rule, but the second 1 is transmitted with the same polarity as the first 1, thus making the second 1 a bipolar violation.

If the transmitter is configured for binary interface format (Section [9.2.2.2](#page-22-0)) and EXZI = 1 then when the configured manual error insert control goes from 0 to 1 the transmitter waits for the next occurrence of three (four) consecutive zeros in the transmit data stream and inhibits the replacement of those zeros with a B3ZS (HDB3) codeword.

The transmitter ensures that there is at least one intervening 1 between consecutive BPV or EXZ errors. If a second error insertion request of a given type (BPV or EXZ) is initiated before a previous request has been completed, the second request is ignored.

#### **9.2.4 AIS Generation**

The transmitter can be configured to transmit an AIS signal by asserting the [TAIS](#page-17-0) pin (hardware interface mode) or the [PORT.CR3:](#page-62-0)TAIS (microprocessor interface mode) configuration bit. In hardware mode, the type of AIS signal to be generated is specified by the [LMn\[1:0\]](#page-17-0) pins. In microprocessor interface mode the type of AIS signal to be generated is specified by [PORT.CR2](#page-61-0):LM[1:0] configuration bits and the [PORT.CR3](#page-62-0):AIST configuration bit. When AIST = 1, the AIS signal is the framed DS3 AIS signal in DS3 mode, unframed all ones in E3 mode, and the AIS-L signal in STS-1 mode. The AIS-L signal is normally scrambled, but scrambling can be disabled by setting [PORT.CR3](#page-62-0):SCRD = 1. When AIST = 0, the AIS signal is unframed all ones in all modes when AIS insertion is requested (TAIS = 1).

#### **9.2.5 Waveshaping**

#### **9.2.5.1 Standards-Compliant Waveshaping**

Waveshaping converts the transmit clock, positive data, and negative data signals into a single analog AMI signal with the waveshape required for interfacing to DS3/E3/STS-1 lines. [Figure 9-1](#page-24-0) and [Table 9-1](#page-24-0) show the DS3 waveform equations and template. [Figure 9-2](#page-25-0) and [Table 9-3](#page-25-0) show the STS-1 waveform equations and template. [Figure 9-3](#page-26-0) shows the E3 waveform template.

#### **9.2.5.2 Programmable Waveshaping**

The transmit waveshape can be adjusted with the TWSC[19:0] bits in the [LIU.TWSCR1](#page-70-0) and [LIU.TWSCR2](#page-71-0) registers. These signals control the amplitude, slew rates and various other aspects of the waveform template. See the register descriptions for further details.

## <span id="page-24-0"></span>**Figure 9-1. DS3 Waveform Template**

PRELIMINARY

## **Table 9-1. DS3 Waveform Equations**

## **Table 9-2. DS3 Waveform Test Parameters and Limits**

## <span id="page-25-0"></span>**Figure 9-2. STS-1 Waveform Template**

PRELIMINARY

## **Table 9-3. STS-1 Waveform Equations**

## **Table 9-4. STS-1 Waveform Test Parameters and Limits**

<span id="page-26-0"></span>

**Table 9-5. E3 Waveform Test Parameters and Limits** 

### **9.2.6 Line Build-Out**

Because DS3 and STS-1 signals must meet the waveform templates at the cross-connect through any cable length from 0 to 450 feet, the waveshaping circuitry includes a selectable LBO feature. For cable lengths of 225 feet or greater, both the [TLBO](#page-18-0) pin (hardware interface mode) and the [LIU.CR1:](#page-68-0)TLBO configuration bit (microprocessor interface mode) should be low to disable the LBO circuitry. When the LBO circuitry is disabled, output pulses are driven onto the coaxial cable without any preattenuation. For cable lengths less than 225 feet, either the [TLBO](#page-18-0) pin (hardware interface mode) or the [LIU.CR1:](#page-68-0)TLBO configuration bit (microprocessor interface mode) should be high to enable the LBO circuitry. When the LBO circuitry is enabled, pulses are preattenuated by the LBO circuitry before being driven onto the coaxial cable to provide attenuation that mimics the attenuation of 225 feet of coaxial cable.

#### <span id="page-27-0"></span>**9.2.7 Line Driver**

The transmit line driver can be disabled [\(TXP](#page-16-0) and [TXN](#page-16-0) outputs high impedance) by deasserting the [TOE](#page-18-0) pin (hardware interface mode) and deasserting the [LIU.CR1:](#page-68-0)TOE (microprocessor interface mode) configuration bit. Powering down the transmitter through the [TPD](#page-18-0) pin (hardware interface mode) or the [PORT.CR1](#page-60-0):TPD (microprocessor interface mode) configuration bit also disables the transmit line driver.

PRELIMINARY

#### **9.2.8 Interfacing to the Line**

The transmitter interfaces to the outgoing DS3/E3/STS-1 coaxial cable (75Ω) through a 1:1 isolation transformer connected to the [TXP](#page-16-0) and [TXN](#page-16-0) pins. The transmit line termination can be internal to the device, external to the device, or a combination of both. [Figure 3-2](#page-7-0) shows the arrangement of the transformer when the internal termination is enabled ([LIU.CR1](#page-68-0):TTRE = 1) and no external termination resistors are used. [Figure 3-3](#page-8-0) shows the arrangement of the transformer and external termination resistors when the internal termination is disabled  $(LIU.CR1:TTRE = 0)$  $(LIU.CR1:TTRE = 0)$  $(LIU.CR1:TTRE = 0)$ . Note that internal termination is only available when a microprocessor interface is enabled. The internal termination resistor value for the transmitter is specified in [LIU.CR1](#page-68-0):TRESADJ. [Table 9-7](#page-28-0) and [Table](#page-28-0)  [9-8](#page-28-0) specify the required characteristics of the transformer and provide a list of recommended transformers.

#### **9.2.9 Driver Monitor and Output Failure Detection**

The transmit driver monitor compares the amplitude of the transmit waveform to thresholds  $V_{TXMM}$  and  $V_{TXMAX}$ . If the amplitude is less than  $V_{TXMIN}$  or greater than  $V_{TXMAX}$  for approximately 32 reference clock cycles, then the monitor sets the [LIU.SR:](#page-72-0)TDM status bit. The setting of LIU.SR:TDM can cause an interrupt if enabled by [LIU.SRIE](#page-74-0):TDMIE. When the transmitter is disabled, the transmit driver monitor is also disabled. The transmit driver monitor is clocked by the LIU's reference clock.

Note that the transmit driver monitor can be affected by reflections caused by shorts and opens on the line. A short circuit at a distance less than a few inches (~11 inches for FR4 material) can introduce inverted reflections that reduce the outgoing pulse amplitude below the  $V_{TXML}$  threshold and thereby activate the TDM status bit. Similarly an open circuit a similar distance away can introduce noninverted reflections that increase the outgoing amplitude above the  $V_{T xMAX}$  threshold and thereby activate the TDM status bit. Shorts and opens at larger distances away from [TXP/TXN](#page-16-0) can also activate the TDM status bit, but this effect is data-pattern dependent.

If either [TXP](#page-16-0) or [RXP](#page-16-0) is not connected (open), shorted to  $V_{DD}$ , or shorted to  $V_{SS}$ , then a transmit failure alarm is declared by setting the [LIU.SR:](#page-72-0)TFAIL status bit. A change of state of the TFAIL status bit can cause an interrupt if enabled by [LIU.SRIE:](#page-74-0)TFAILIE. TFAIL is cleared when activity is detected on both [TXP](#page-16-0) and [RXP.](#page-16-0)

#### **9.2.10 Power-Down**

To minimize power consumption when the transmitter is not being used, the [TPD](#page-18-0) pin (hardware interface mode for all ports) or the [PORT.CR1](#page-60-0):TPD configuration bit (microprocessor interface mode for each port) can be asserted. When the transmitter is powered down, the [TXP](#page-16-0) and [TXN](#page-16-0) pins are put in a high-impedance state and the transmit drivers are powered down.

#### **9.2.11 Jitter Generation (Intrinsic)**

The transmitter meets the jitter generation requirements of all applicable standards in [Table 9-6](#page-27-0), with or without the jitter attenuator enabled. Generated jitter is measured with a jitter-free, 0ppm input clock.

#### **Table 9-6. Jitter Generation**

#### <span id="page-28-0"></span>**9.2.12 Jitter Transfer**

Without the jitter attenuator on the transmit side, the transmitter passes jitter through unchanged. With the jitter attenuator enabled on the transmit side, the transmitter meets the jitter transfer requirements of all applicable telecommunication standards in [Table 2-1](#page-6-0). See [Figure 9-7.](#page-34-0)

#### **9.3 Receiver**

#### **9.3.1 Interfacing to the Line**

The receiver can be transformer-coupled or capacitor-coupled to the line. Typically, the receiver interfaces to the incoming coaxial cable (75Ω) through a 1:1 isolation transformer. The receive line termination can be internal to the device, external to the device, or a combination of both. [Figure 3-2](#page-7-0) shows the arrangement of the transformer when the internal termination is enabled [\(LIU.CR2](#page-69-0):RTRE = 1) and no external termination resistors are used. [Figure 3-3](#page-8-0) shows the arrangement of the transformer and external termination resistors when the internal termination is disabled ([LIU.CR2](#page-69-0):RTRE = 0). Note that internal termination is only available when a microprocessor interface is enabled. The internal termination resistor value is specified in [LIU.CR2](#page-69-0):RRESADJ[3:0]. [Table 9-7](#page-28-0) and [Table 9-8](#page-28-0) specify the required characteristics of the transformer and provide a list of recommended transformers. The receiver expects the incoming signal to be in B3ZS- or HDB3-coded AMI format.

#### **Table 9-8. Recommended Transformers**

**Note:** Table subject to change. Multiport transformers are also available. Contact the manufacturer for details at [www.pulseeng.com](http://www.pulseeng.com/) and *[www.haloelectronics.com.](http://www.haloelectronics.com/)* 

#### **9.3.2 Optional Preamp**

The receiver can be used in monitoring applications, which typically have series resistors with a resistive loss of approximately 20dB. When the [RMON](#page-18-0) pin (hardware interface mode) is high or the [LIU.CR2:](#page-69-0)RMON (microprocessor interface mode) configuration bit is set, the receiver can compensate for this resistive loss by applying 14dB of additional flat gain to the incoming signal before sending the signal to the AGC/equalizer block (an additional 6dB of flat gain is applied in the AGC circuitry for a total gain of 20dB). When the preamp is enabled the receiver automatically determines whether or not to make use of the preamp's additional gain. Status bit [LIU.SR:](#page-72-0)RPAS indicates whether or not the preamp is in use. A change of state of [LIU.SR](#page-72-0):RPAS can cause an interrupt if enabled by [LIU.SRIE](#page-74-0):RPASIE.

#### <span id="page-29-0"></span>**9.3.3 Automatic Gain Control (AGC) and Adaptive Equalizer**

The AGC circuitry applies flat (frequency independent) gain to the incoming signal to compensate for flat losses in the transmission channel and variations in transmission power. Since the incoming signal also experiences frequency-dependent losses as it passes through the coaxial cable, the adaptive equalizer circuitry applies frequency-dependent gain to offset line losses and restore the signal. The AGC/equalizer circuitry automatically adapts to coaxial cable losses from 0 to 22dB, which translates into 0 to 457 meters (1500 feet) of coaxial cable (AT&T 734A or equivalent). The AGC and the equalizer work simultaneously but independently to supply a signal of nominal amplitude and pulse shape to the clock and data recovery block. The AGC/equalizer block automatically handles direct (0 meters) monitoring of the transmitter output signal. The real-time receiver gain level can be read from the [LIU.RGLR](#page-75-0) register.

PRELIMINARY

#### **9.3.4 Clock and Data Recovery (CDR)**

The CDR block takes the amplified, equalized signal from the AGC/equalizer block and produces separate clock, positive data, and negative data signals. The CDR operates from the LIU's reference clock. See Section [9.7.1](#page-39-0) for more information about reference clocks and clock selection.

The receiver locks onto the incoming signal using a clock recovery PLL. The PLL lock status is indicated in the [LIU.SR:](#page-72-0)RLOL status bit. The RLOL bit is set when the difference between recovered clock frequency and reference clock frequency is greater than 7900ppm and cleared when the difference is less than 7700ppm. A change of state of the RLOL status bit can cause an interrupt if enabled by [LIU.SRIE:](#page-74-0)RLOLIE. Note that if the reference clock is not present, RLOL is not set.

#### **9.3.5 Loss-of-Signal (LOS) Detector**

The receiver contains analog and digital LOS detectors. The analog LOS (ALOS) detector resides in the AGC/equalizer block. At approximately 23dB below nominal pulse amplitude ALOS is declared by setting the [LIU.SR:](#page-72-0)ALOS status bit. A change of state of the ALOS status bit can cause an interrupt if enabled by [LIU.SRIE](#page-74-0):ALOSIE. When ALOS is declared the CDR block forces all zeros out of the data recovery circuit, causing digital LOS (DLOS), which is indicated by the [RLOS](#page-18-0) pin and the [LINE.RSR:](#page-80-0)RLOS status bit. During ALOS the [RCLK](#page-16-0) pin follows the LIU's reference clock, since no clock information is being received on [RXP/RXN.](#page-16-0) ALOS is cleared at approximately 22dB below nominal pulse amplitude. When the preamp is enabled (section [9.3.2](#page-28-0)) ALOS is declared at approximately 37dB below nominal and cleared at approximately 36dB below nominal.

The digital LOS detector declares DLOS when it detects 192 consecutive zeros in the recovered data stream. When DLOS occurs, the receiver asserts the [RLOS](#page-18-0) pin (if the hardware interface is enabled) and the [LINE.RSR:](#page-80-0)RLOS status bit. DLOS is cleared when there are no EXZ occurrences over a span of 192 clock periods. An EXZ occurrence is defined as three or more consecutive zeros in DS3 and STS-1 modes and four or more consecutive zeros in E3 mode. The [RLOS](#page-18-0) pin and the RLOS status bit are deasserted when the DLOS condition is cleared. A change of state of the [LINE.RSR:](#page-80-0)RLOS status bit can cause an interrupt if enabled by [LINE.RSRIE](#page-81-0):RLOSIE. DLOS is only declared when B3ZS/HDB3 decoding is enabled ([LINE.RCR](#page-79-0):RZSD = 0). When B3ZS/HDB3 decoding is disabled in the LIU, decoding should be enabled in the neighboring DS3/E3 framer, and DLOS should be detected and report by the framer.

The requirements of ANSI T1.231 and ITU-T G.775 for DS3 LOS defects are met by the DLOS detector, which asserts RLOS when it counts 192 consecutive zeros coming out of the CDR block and clears RLOS when it counts 192 consecutive pulse intervals without excessive zero occurrences.

The requirements of ITU-T G.775 for E3 LOS defects are met by a combination of the ALOS detector and the DLOS detector, as follows:

#### **For E3 RLOS Assertion:**

- 1) The ALOS detector in the AGC/equalizer block detects that the incoming signal is less than or equal to a signal level approximately 23 dB below nominal, and mutes the data coming out of the clock and data recovery block. (23 dB below nominal is in the "tolerance range" of G.775, where LOS may or may not be declared.)
- 2) The DLOS detector counts 192 consecutive zeros coming out of the CDR block and asserts RLOS. (192 meets the 10  $\leq$  N  $\leq$  255 pulse-interval duration requirement of G.775.)

#### <span id="page-30-0"></span>**For E3 RLOS Clear:**

- 1) The ALOS detector in the AGC/equalizer block detects that the incoming signal is greater than or equal to a signal level approximately 22 dB below nominal, and enables data to come out of the CDR block. (22 dB is in the "tolerance range" of G.775, where LOS may or may not be declared.)
- 2) The DLOS detector counts 192 consecutive pulse intervals without EXZ occurrences and deasserts RLOS. (192 meets the 10  $\leq$  N  $\leq$  255 pulse-interval duration requirement of G.775.)

The DLOS detector supports the requirements of ANSI T1.231 for STS-1 LOS defects. At the STS-1 rate, the time required for the DLOS detector to count 192 consecutive zeros falls in the range of  $2.3 \le T \le 100 \mu s$  required by ANSI T1.231 for declaring an LOS defect. Although the time required for the DLOS detector to count 192 consecutive pulse intervals with no excessive zeros is less than the 125 μs to 250 μs period required by ANSI T1.231 for clearing an LOS defect, a period of this length where LOS is inactive can easily be timed in software.

During LOS, the [RCLK](#page-16-0) output pin is derived from the LIU's reference clock. The ALOS detector has a longer time constant than the DLOS detector. Thus, when the incoming signal is lost, the DLOS detector activates first (asserting the [RLOS](#page-18-0) pin and RLOS status bit), followed by the ALOS detector. When a signal is restored, the DLOS detector does not get a valid signal that it can qualify for no EXZ occurrences until the ALOS detector has seen the signal rise above a signal level approximately 22dB below nominal.

#### **9.3.6 Framer Interface Format and the B3ZS/HDB3 Decoder**

The recovered data can be output in either bipolar or binary format. Reception of a B3ZS or HDB3 codeword is flagged by the [LINE.RSRL:](#page-80-0)ZSCDL latched status bit.

#### **9.3.6.1 Bipolar Interface Format**

To select the bipolar interface format, pull the [RBIN](#page-18-0) pin (hardware interface mode) low and clear the [PORT.CR2](#page-61-0):RBIN configuration bit (microprocessor interface mode). In bipolar format, the B3ZS/HDB3 decoder is disabled and the recovered data is buffered and output on the [RPOS](#page-16-0) and [RNEG](#page-16-0) outputs for subsequent decoding by a downstream framer or mapper. Received positive-polarity pulses are indicated by [RPOS](#page-16-0) = 1, while negativepolarity pulses are indicated by [RNEG](#page-16-0) = 1.

In DS3 and STS-1 modes an excessive zeros error (EXZ) is declared whenever there is an occurrence of 3 or more zeros in a row in the receive data stream. In E3 mode, an EXZ error is declared whenever there is an occurrence of 4 or more zeros. EXZs are flagged by the [LINE.RSRL](#page-80-0):EXZL and EXZCL latched status bits and accumulated in the [LINE.REXZCR](#page-82-0) register.

In all three modes (DS3, E3, and STS-1) a bipolar violation is declared if two positive pulses are received without an intervening negative pulse or if two negative pulses are received without an intervening positive pulse. Bipolar violations (BPVs) are flagged by the [LINE.RSRL:](#page-80-0)BPVL and BPVCL latched status bits and accumulated in the [LINE.RBPVCR](#page-82-0) register.

#### **9.3.6.2 Binary Interface Format**

To select the binary interface format, pull the [RBIN](#page-18-0) pin high (hardware interface mode for all ports) or set the [PORT.CR2](#page-61-0):RBIN configuration bit (microprocessor interface mode for each port). In binary format, the B3ZS/HBD3 decoder is enabled, and the recovered data is decoded and output as a binary (NRZ) value on the [RDAT](#page-16-0) pin, while bipolar violations, code violations, and excessive zero errors are detected and flagged on the [RLCV](#page-16-0) pin.

In DS3 and STS-1 modes, B3ZS decoding is performed. In these modes, whenever a B3ZS codeword is found in the receive data stream it is replaced with three zeros. In E3 mode HDB3 decoding is performed. In this mode, whenever an HDB3 codeword is found in the receive data stream it is replaced with four zeros. The decoding search criteria for a B3ZS/HDB3 codeword is programmable using the [LINE.RCR:](#page-79-0)RDZSF control bit.

An excessive zeros error (EXZ) is declared in DS3 and STS-1 modes whenever there is an occurrence of 3 or more zeros in a row in the receive data stream. In E3 mode, an EXZ error is declared whenever there is an occurrence of 4 or more zeros in a row. EXZs are flagged by the [LINE.RSRL:](#page-80-0)EXZL and EXZCL latched status bits and accumulated in the [LINE.REXZCR](#page-82-0) register.

A bipolar violation error (BPV error) is declared in DS3 and STS-1 modes if a BPV is detected that is not part of a valid B3ZS codeword. In E3 mode, a bipolar violation error is declared whenever a BPV is detected that is not part of a valid HDB3 codeword. In E3 mode if [LINE.RCR:](#page-79-0)E3CVE = 1, code violations are detected rather than bipolar violation errors. A code violation is declared whenever consecutive BPVs (not BPV errors) have the same polarity (ITU O.161 definition). The error detection search criteria for a B3ZS/HDB3 codeword is programmable using the

<span id="page-31-0"></span>[LINE.RCR](#page-79-0):REZSF control bit. Bipolar violations (or code violations if [LINE.RCR](#page-79-0):E3CVE = 1) are flagged by the [LINE.RSRL](#page-80-0):BPVL and BPVCL latched status bits and accumulated in the [LINE.RBPVCR](#page-82-0) register.

In the discussion that follows, a valid pulse that conforms to the AMI rule is denoted as B. A BPV pulse that violates the AMI rule is denoted as V.

In DS3 and STS-1 modes, B3ZS decoding is performed, and [RLCV](#page-16-0) is asserted during any [RCLK](#page-16-0) cycle where the data on [RDAT](#page-16-0) causes ones of the following code violations:

- $\blacksquare$  When LINE.RCR:E3CVE = 0:
	- [A BPV immediately preceded by a valid](#page-22-0) pulse (B, V).
	- A BPV with the same polarity as the last BPV.
	- The third zero in an EXZ.
- $\blacksquare$  When LINE.RCR:E3CVE = 1:
	- [A B](#page-23-0)PV immediately preceded by a valid pulse (B, V).
	- A BPV with the same polarity as the last BPV.

In E3 mode, HDB3 decoding is performed, and [RLCV](#page-16-0) is asserted during any [RCLK](#page-16-0) cycle where the data on [RDAT](#page-16-0) causes one of the following code violations:

- $W$  When LINE.RCR:E3CVE = 0:
	- $-$  A BPV immediately preceded by a valid pulse  $(B, V)$  or by a valid pulse and a zero  $(B, 0, V)$ .
	- A BPV with the same polarity as the last BPV.
	- The fourth zero in an EXZ.
- When  $LINE.RCR:ESCVE = 1$ :
	- [A BPV with](#page-27-0) the same polarity as the last BPV.

In any cycle where [RLCV](#page-16-0) is asserted to flag a BPV, the [RDAT](#page-16-0) pin outputs a one. In any cycle where RLCV is asserted to flag an EXZ, the [RDAT](#page-16-0) pin outputs a zero. The state bit that tracks the polarity of the last BPV is toggled on every BPV, whether part of a valid B3ZS/HDB3 codeword or not.

#### **9.3.6.3 RCLK Inversion**

The polarity of [RCLK](#page-16-0) can be inverted to support a glueless interface to a variety of neighboring components. Normally, data is output on the [RPOS/RDAT](#page-16-0) and [RNEG/RLCV](#page-16-0) pins on the falling edge of [RCLK.](#page-16-0) To output data on these pins on the rising edge of [RCLK,](#page-16-0) pull the [RCLKI](#page-18-0) pin (hardware interface mode) high or set the [PORT.INV:](#page-63-0)RCLKI configuration bit (microprocessor interface mode).

#### **9.3.6.4 Receiver Output Disable**

The [RCLK,](#page-16-0) [RPOS/RDAT](#page-16-0) and [RNEG](#page-16-0)/[RLCV](#page-16-0) pins can be disabled (put in a high-impedance state) to support protection switching and redundant-LIU applications. This capability supports system configurations where two or more LIUs are wire-ORed together and a system processor selects one to be active. To disable these pins, set the [PORT.CR2](#page-61-0):ROD configuration bit.

#### **9.3.7 Power-Down**

To minimize power consumption when the receiver is not being used, assert the [RPD](#page-18-0) pin (hardware interface mode for all ports) or the [PORT.CR1](#page-60-0):RPD configuration bit (microprocessor interface mode per port). When the receiver is powered down, the [RCLK,](#page-16-0) [RPOS/RDAT](#page-16-0) and [RNEG/RLCV](#page-16-0) pins are disabled (high impedance). In addition, the [RXP](#page-16-0) and [RXN](#page-16-0) pins become high impedance.

#### **9.3.8 Input Failure Detection**

The LIU receiver can detect opens and shorts on the [RXP](#page-16-0) and [RXN](#page-16-0) differential inputs. By default, the receiver detects the following problems, collectively labeled type 1 failures: open [RXP](#page-16-0) connection, open [RXN](#page-16-0) connection, common-mode [RXP](#page-16-0)/[RXN](#page-16-0) short to VDD, and common-mode [RXP/RXN](#page-16-0) short to VSS. Type 1 failures are reported on [LIU.SR:](#page-72-0)RFAIL1. RFAIL1 is cleared when activity is detected on both [RXP](#page-16-0) and [RXN](#page-16-0).

If [LIU.CR2](#page-69-0):RFL2E = 1, the receiver also detects a type 2 failure, which is an open or high-impedance path between [RXP](#page-16-0) and [RXN](#page-16-0). On a board with the external components shown in [Figure 3-2](#page-7-0) or [Figure 3-3,](#page-8-0) the receive transformer normally presents a low-impedance path between [RXP](#page-16-0) and [RXN](#page-16-0). To detect a type 2 failure, the receiver connects an 40 µA DC current source to [RXP](#page-16-0) and measures the impedance between [RXP](#page-16-0) and [RXN.](#page-16-0)

<span id="page-32-0"></span>When this impedance is greater than about 5 kΩ the receiver declares a type 2 failure on [LIU.SR](#page-72-0):RFAIL2. When the type 2 failure-detection circuitry is enabled, internal termination must be disabled [\(LIU.CR2:](#page-69-0)RTRE = 0) and external termination must not be present or a type 2 failure will not be detected because the impedance of the termination is below the type 2 failure threshold.

#### **9.3.9 Jitter and Wander Tolerance**

The receiver exceeds the input jitter tolerance requirements of all applicable telecommunication standards in [Table 2-1](#page-6-0). See [Figure 9-4](#page-32-0) for STS-1 and E3 jitter tolerance characteristics. See [Figure 9-5](#page-33-0) for DS3 jitter tolerance characteristics. See [Figure 9-6](#page-33-0) for DS3 and E3 wander tolerance characteristics. **Note:** Only G.823 and G.824 have wander tolerance requirements.

#### **Figure 9-4. STS-1 and E3 Jitter Tolerance**

## <span id="page-33-0"></span>**Figure 9-5. DS3 Jitter Tolerance**

PRELIMINARY

**Figure 9-6. DS3 and E3 Wander Tolerance** 

#### **9.3.10 Jitter Transfer**

Without the jitter attenuator on the receive side, the receiver attenuates jitter at frequencies above its corner frequency (approximately 300kHz) and passes jitter at lower frequencies. With the jitter attenuator enabled on the receive side, the receiver meets the jitter transfer requirements of all applicable telecommunication standards in [Table 2-1.](#page-6-0) See [Figure 9-7.](#page-34-0)

#### <span id="page-34-0"></span>**9.4 Jitter Attenuator**

Each LIU contains an on-board jitter attenuator that can be placed in the receive path or the transmit path or can be disabled. When the hardware interface is enabled [\(IFSEL](#page-17-0) = 00X), the [JAS\[1:0\]](#page-18-0) and [JAD\[1:0\]](#page-18-0) pins specify the jitter attenuator location and buffer depth for all ports. When a microprocessor interface is enabled [\(IFSEL](#page-17-0) ≠ 00X), the [LIU.CR1](#page-68-0):JAS[1:0] and JAD[1:0] configuration bits specify the JA location and buffer depth for each port individually. The JA buffer depth can be set to 16, 32, 64 or 128 bits. [Figure 9-7](#page-34-0) shows the minimum jitter attenuation for the device when the jitter attenuator is enabled. [Figure 9-7](#page-34-0) also shows the receive jitter transfer when the jitter attenuator is disabled.

The jitter attenuator consists of a narrowband PLL to retime the selected clock, a FIFO to buffer the associated data while the clock is being retimed, and logic to prevent FIFO over/underflow in the presence of very large jitter amplitudes. The JA has a loop bandwidth of reference clock  $\div$  2,058,874 (see corner frequencies in [Figure 9-7](#page-34-0)). The JA attenuates jitter at frequencies higher than the loop bandwidth, while allowing jitter (and wander) at lower frequencies to pass through relatively unaffected.

The jitter attenuator requires a transmission-quality reference clock (i.e.,  $\pm 20$ ppm frequency accuracy and low jitter). See Section [9.7.1](#page-39-0) for more information about reference clocks and clock selection.

When the microprocessor interface is enabled, the jitter attenuator indicates the fill status of its FIFO buffer in the [LIU.SRL](#page-73-0):JAFL (JA full) and [LIU.SRL:](#page-73-0)JAEL (JA empty) status bits. When the buffer becomes full, the JA momentarily increases the frequency of the read clock by 6250ppm to avoid buffer overflow and consequent data errors. When the buffer becomes empty, the JA momentarily decreases the frequency of the read clock by 6250 ppm to avoid buffer underflow and consequent data errors. During these momentary frequency adjustments, jitter is passed through the JA to avoid over/underflow. If the phase noise or frequency offset of the write clock is large enough to cause the buffer to overflow or underflow, the JA sets *both* the JAFL bit *a*n*d* the JAEL bit to indicate that data errors have occurred. JAFL and JAEL can cause an interrupt if enabled by the corresponding enable bits in the [LIU.SRIE](#page-74-0) register.

As shown in [Figure 9-7,](#page-34-0) the jitter attenuator meets the jitter transfer requirements of all applicable standards listed in [Table 2-1](#page-6-0).

### **Figure 9-7. Jitter Attenuation/Jitter Transfer**

## <span id="page-35-0"></span>**9.5 BERT**

Each LIU port has a built-in bit error rate tester (BERT). The BERT is a software-programmable test-pattern generator and monitor capable of meeting most error performance requirements for digital transmission equipment. It can generate and synchronize to pseudo-random patterns with a generation polynomial of the form  $x^n + x^y + 1$ , (where n and y can take on values from 1 to 32 with  $y < n$ ) and to repetitive patterns of any length up to 32 bits. The pattern generator generates the programmable test pattern, and inserts the test pattern into the data stream. The pattern detector extracts the test pattern from the receive data stream and monitors it. [Figure 5-1](#page-10-0) shows the location of the BERT Block within the DS3250x devices.

PRELIMINARY

#### **9.5.1 Configuration and Monitoring**

The pattern detector is always enabled. The pattern generator is enabled by setting the [PORT.CR3](#page-62-0):BERTE configuration bit. When the BERT is enabled and [PORT.CR3](#page-62-0):BERTD = 0, the pattern is transmitted and received in the line direction, i.e., the pattern generator is the data source for the transmitter, and the receiver is the data source for the pattern detector. When the BERT is enabled and [PORT.CR3](#page-62-0):BERTD = 1, the pattern is transmitted and received in the system direction, i.e., the pattern generator is the data source for the [RPOS/RDAT](#page-16-0) and [RNEG/RLCV](#page-16-0) pins, and the [TPOS](#page-16-0)/[TDAT](#page-16-0) and [TNEG](#page-16-0) pins are the data source for the pattern detector. See [Figure](#page-10-0)  [5-1.](#page-10-0)

The I/O of the BERT are binary (NRZ) format. Thus while the BERT is enabled, both [PORT.CR2:](#page-61-0)RBIN and [PORT.CR2](#page-61-0):TBIN must be set to 1 for proper operation. In addition, while transmitting/receiving BERT patterns in the system direction [\(PORT.CR3:](#page-62-0)BERTD = 1), the neighboring framer or mapper component must also be configured for binary interface mode to match the LIU. If the LIU interface is normally bipolar, the interface can be changed back to bipolar mode when the system is done using the BERT function ([PORT.CR3](#page-62-0):BERTE = 0).

The following tables show how to configure the BERT to send and receive common patterns.

#### **Table 9-9. Pseudorandom Pattern Generation**

#### **Table 9-10. Repetitive Pattern Generation**

After configuring these bits, the pattern must be loaded into the BERT. This is accomplished via a zero-to-one transition on [BERT.CR](#page-84-0).TNPL for the pattern generator and [BERT.CR.](#page-84-0)RNPL for the pattern detector. The BERT must be enabled ([PORT.CR3](#page-62-0):BERTE = 1) before the pattern is loaded for the pattern load operation to take effect.

Monitoring the BERT requires reading the [BERT.SR](#page-88-0) register, which contains the Bit Error Count (BEC) bit and the Out of Synchronization (OOS) bit. The BEC bit is set to one when the bit error counter is one or more. The OOS bit is set to one when the pattern detector is not synchronized to the incoming pattern, which occurs when it receives 6 or more bit errors within a 64-bit window. The Receive BERT Bit Count Register [\(BERT.RBCR](#page-91-0)) and the Receive BERT Bit Error Count Register ([BERT.RBECR](#page-90-0)) are updated upon the reception of a Performance Monitor Update signal (e.g., [BERT.CR](#page-84-0).LPMU). This signal updates the registers with the bit and bit-error counts since the last update and then resets the counters. See Section [9.7.4](#page-42-0) for more details about performance monitor updates.

### **9.5.2 Receive Pattern Detection**

The pattern detector synchronizes the receive pattern generator to the incoming pattern. The receive pattern generator is a 32-bit shift register that shifts data from the least significant bit (LSB) or bit 1 to the most significant bit (MSB) or bit 32. The input to bit 1 is the feedback. For a PRBS pattern (generating polynomial  $x^n + x^y + 1$ ), the feedback is an XOR of bit n and bit y. For a repetitive pattern (length n), the feedback is bit n. The values for n and y are individually programmable (1 to 32 with  $y < n$ ) in the [BERT.PCR](#page-85-0):PLF and PTF fields. The output of the receive pattern generator is the feedback. If QRSS is enabled [\(BERT.PCR](#page-85-0):QRSS = 1), the feedback is forced to be an XOR of bits 17 and 20, and the output is forced to one if the next 14 bits are all zeros. For PRBS and QRSS patterns, the feedback is forced to one if bits 1 through 31 are all zeros. Depending on the type of pattern programmed, pattern detection performs either PRBS synchronization or repetitive pattern synchronization.

### **9.5.2.1 Receive PRBS Synchronization**

PRBS synchronization synchronizes the receive pattern generator to the incoming PRBS or QRSS pattern. The receive pattern generator is synchronized by loading 32 data stream bits into the receive pattern generator, and then checking the next 32 data stream bits. Synchronization is achieved if all 32 bits match the incoming pattern. If at least six incoming bits in the current 64-bit window do not match the receive pattern generator, automatic pattern resynchronization is initiated. Automatic pattern resynchronization can be disabled by setting [BERT.CR](#page-84-0):APRD = 1. Pattern resynchronization can also be initiated manually by a zero-to-one transition of the Manual Pattern Resynchronization bit [\(BERT.CR](#page-84-0):MPR). The incoming data stream can be inverted before comparison with the receive pattern generator by setting [BERT.CR:](#page-84-0)RPIC. Refer to [Figure 9-8](#page-37-0) for the PRBS synchronization state diagram.

### <span id="page-37-0"></span>**Figure 9-8. PRBS Synchronization State Diagram**

PRELIMINARY

#### **9.5.2.2 Receive Repetitive Pattern Synchronization**

Repetitive pattern synchronization synchronizes the receive pattern generator to the incoming repetitive pattern. The receive pattern generator is synchronized by searching each incoming data stream bit position for the repetitive pattern, and then checking the next 32 data stream bits. Synchronization is achieved if all 32 bits match the incoming pattern. If at least six incoming bits in the current 64-bit window do not match the receive PRBS pattern generator, automatic pattern resynchronization is initiated. Automatic pattern resynchronization can be disabled by setting [BERT.CR:](#page-84-0)APRD = 1. Pattern resynchronization can also be initiated manually by a zero-to-one transition of the Manual Pattern Resynchronization bit ([BERT.CR:](#page-84-0)MPR). The incoming data stream can be inverted before comparison with the receive pattern generator by setting [BERT.CR](#page-84-0):RPIC.

See [Figure 9-9](#page-38-0) for the repetitive pattern synchronization state diagram.

### <span id="page-38-0"></span>**Figure 9-9. Repetitive Pattern Synchronization State Diagram**

PRELIMINARY

#### **9.5.2.3 Receive Pattern Monitoring**

Receive pattern monitoring monitors the incoming data stream for both an OOS condition and bit errors and counts the incoming bits. An out-of-synchronization ([BERT.SR](#page-88-0):OOS = 1) condition is declared when the synchronization state machine is not in the "Sync" state. An OOS condition is terminated when the synchronization state machine is in the "Sync" state. A change of state of the OOS status bit sets the [BERT.SRL](#page-88-0):OOSL latched status bit and can cause an interrupt if enabled by [BERT.SRIE:](#page-89-0)OOSIE.

Bit errors are determined by comparing the incoming data stream bit to the receive pattern generator output. If the two bits do not match, a bit error is declared ([BERT.SRL:](#page-88-0)BEL = 1), and the bit error and bit counts are incremented ([BERT.RBECR](#page-90-0) and [BERT.RBCR](#page-91-0), respectively). If the two bits do match, only the bit count is incremented. The bit count and bit error count are not incremented when an OOS condition exists. The setting of the BEL status bit can cause an interrupt if enabled by [BERT.SRIE:](#page-89-0)BEIE.

### **9.5.3 Transmit Pattern Generation**

The pattern generator generates the outgoing test pattern. The transmit pattern generator is a 32-bit shift register that shifts data from the least significant bit (LSB) or bit 1 to the most significant bit (MSB) or bit 32. The input to bit 1 is the feedback. For a PRBS pattern (generating polynomial  $x^n + x^y + 1$ ), the feedback is an XOR of bit n and bit y. For a repetitive pattern (length n), the feedback is bit n. The values for n and y are individually programmable (1 to 32 with y < n) in the [BERT.PCR](#page-85-0):PLF and PTF fields. The output of the receive pattern generator is the feedback. If QRSS is enabled [\(BERT.PCR:](#page-85-0)QRSS = 1), the feedback is forced to be an XOR of bits 17 and 20, and the output is forced to one if the next 14 bits are all zeros. For PRBS and QRSS patterns, the feedback is forced to one if bits 1 through 31 are all zeros. When a new pattern is loaded, the pattern generator is loaded with a seed/pattern value before pattern generation starts. The seed/pattern value is programmable  $(0 - 2<sup>n</sup> - 1)$  in the [BERT.SPR](#page-86-0) registers. The generated pattern can be inverted by setting [BERT.CR:](#page-84-0)TPIC.

#### **9.5.3.1 Transmit Error Insertion**

Errors can be inserted into the generated pattern one at a time or at a rate of one out of every 10<sup>n</sup> bits. The value of n is programmable (1 to 7 or off) in the [BERT.TEICR:](#page-87-0)TEIR[2:0] configuration field. Single bit error insertion is

<span id="page-39-0"></span>enabled by setting [BERT.TEICR:](#page-87-0)BEI and can be initiated from the microprocessor interface or by the manual error insertion pin (GPIOB2). See Section [9.7.5](#page-42-0) for more information about manual error insertion.

### **9.6 Loopbacks**

Each LIU has three internal loopbacks. See [Figure 5-1](#page-10-0). When the hardware interface is enabled [\(IFSEL](#page-17-0) =  $00X$ ), loopbacks are controlled by the [LBn\[1:0\].](#page-19-0) When a microprocessor interface is enabled ([IFSEL](#page-17-0)≠00X), loopbacks are controlled by the LB[1:0] and LBS fields in the [PORT.CR3](#page-62-0) register.

Analog loopback (ALB) connects the outgoing transmit signal back to the receiver's analog front end. During ALB the transmit signal is output normally on [TXP/TXN,](#page-16-0) but the received signal on [RXP/RXN](#page-16-0) is ignored.

Line loopback (LLB) connects the output of the receiver to the input of the transmitter. The LLB path does not include the B3ZS/HDB3 decoder and encoder so that the signal looped back is exactly the same as the signal received, including bipolar violations and code violations. During LLB, recovered clock and data are output on [RCLK](#page-16-0), [RPOS](#page-16-0)/[RDAT](#page-16-0), and [RNEG](#page-16-0)/[RLCV](#page-16-0), but the [TPOS/TDAT](#page-16-0) and [TNEG](#page-16-0) pins are ignored.

Diagnostic loopback (DLB) connects the TCLK, TPOS/TDAT and TNEG pins to the [RCLK](#page-16-0), [RPOS](#page-16-0)/[RDAT](#page-16-0), and [RNEG/RLCV](#page-16-0) pins. During DLB (with LLB disabled), the signal on [TXP/TXN](#page-16-0) can be the normal transmit signal or an AIS signal from the AIS generator. In microprocessor interface mode DLB and LLB can be enabled simultaneously to provide simultaneous remote and local loopbacks.

### **9.7 Global Resources**

### **9.7.1 Clock Rate Adapter (CLAD)**

The CLAD is used to create multiple transmission-quality reference clocks from a single transmission-quality (±20ppm, low jitter) clock input on the [REFCLK](#page-20-0) pin. The LIUs in the device need up to three different reference clocks (DS3, E3, and STS-1) for use by the CDRs and jitter attenuators. Given one of these clock rates or any of several other clock frequencies on the [REFCLK](#page-20-0) pin, the CLAD can generate all three LIU reference clocks. The internally generated reference clock signals can optionally be driven out on pins [CLKA,](#page-20-0) [CLKB](#page-20-0), and [CLKC](#page-20-0) for external use. In addition a fourth frequency, either 77.76 MHz or 19.44 MHz, can be generated and driven out on the [CLKD](#page-20-0) pin for use in Telecom Bus applications.

When the hardware interface is enabled [\(IFSEL](#page-17-0) =  $00X$ ), the CLAD is controlled by the [CLADBYP](#page-19-0) pin, and the [REFCLK](#page-20-0) frequency is fixed at 19.44 MHz. When the [CLADBYP](#page-19-0) pin is high all PLLs in the CLAD are bypassed and powered down, and the [REFCLK](#page-20-0) pin is ignored. In this mode the [CLKA](#page-20-0), [CLKB,](#page-20-0) and [CLKC](#page-20-0) pins become inputs, and the DS3, E3 and STS-1 reference clocks, respectively, are sourced from these pins. Transmission-quality clocks ( $\pm$ 20ppm, low jitter) must be provided to these pins for each line rate required by the LIUs. When CLADBYP is low, [all four PLLs in th](#page-26-0)e CLAD are enabled, and the generated DS3, E3, STS-1, and 77.76/19.44MHz clocks are always output on [CLKA](#page-20-0), [CLKB, CLKC](#page-20-0) and [CLKD,](#page-20-0) respectively.

When a microprocessor interface is enabled ([IFSEL](#page-17-0)≠00X), the CLAD clock mode and the [REFCLK](#page-20-0) frequency are set by the [GLOBAL.CR2:](#page-54-0)CLAD[6:4] bits, as shown in [Table 9-11](#page-40-0). When CLAD[6:4] = 000, all PLLs in the CLAD are bypassed and powered down, and the [REFCLK](#page-20-0) pin is ignored. In this mode the [CLKA,](#page-20-0) [CLKB](#page-20-0), and [CLKC](#page-20-0) pins become inputs, and the DS3, E3 and STS-1 reference clocks, respectively, are sourced from these pins. Transmission-quality clocks (±20ppm, low jitter) must be provided to these pins for each line rate required by the LIUs. CLAD[6:4] = 000 is equivalent to pulling the [CLADBYP](#page-19-0) pin high in hardware interface mode. When  $CLAD[6:4] \neq 000$ , the PLL circuits are enabled as needed to generate the required clocks, as determined by the CLAD[6:0] bits and the LIU mode bits ([PORT.CR2](#page-61-0):LM[1:0]). If a clock rate is not required as a reference clock, then the PLL used to generate that clock is automatically disabled and powered down. The CLAD[3:0] bits are output enable controls for [CLKA](#page-20-0), [CLKB, CLKC](#page-20-0) and [CLKD](#page-20-0), respectively. Configuration bit [GLOBAL.CR2:](#page-54-0)CLKD19 specifies the frequency to be output on the CLKD pin (77.76MHz or 19.44MHz). Status register [GLOBAL.SRL](#page-57-0) provides activity status for the [REFCLK, CLKA, CLKB](#page-20-0) and [CLKC](#page-20-0) pins and lock status for the CLAD.

Each LIU block indicates the absence of the reference clock it requires by setting its [LIU.SR:](#page-72-0)LOMC bit.

\**When CLAD[6:4] = 000, CLKA, CLKB, and CLKC are inputs and CLKD is held low.*

### <span id="page-41-0"></span>**9.7.2 One-Second Reference Generator**

The one-second reference signal can be used to update performance monitoring registers on a precise onesecond interval. The generated internal signal is a 50% duty cycle signal that is divided down from the indicated reference signal. The low to high edge on this signal sets the [GLOBAL.SRL:](#page-57-0)1SREFL latched one-second bit, which can generate an interrupt if enabled. The low to high edge is used to initiate a performance monitor register update when [GLOBAL.CR1](#page-53-0):GPM[1:0] = 1X. The internal one-second reference can be output on the GPIOB3 pin by setting [GLOBAL.CR1](#page-53-0):G1SROE. The source for the one-second reference is set by GLOBAL.CR1:G1SRS[2:0]. The DS3, E3 and STS-1 reference clocks are sourced from the CLAD, if the CLAD is configured to generate them, or from the CLKA, CLKB and CLKC pins, respectively.

PRELIMINARY

### **Table 9-13. Global One-Second Reference Source**

### **9.7.3 General-Purpose I/O Pins**

When a microprocessor interface is enabled ([IFSEL](#page-17-0)  $\neq$  00X), there are two general-purpose I/O (GPIO) pins available per port, each of which can be used as a general-purpose input, general-purpose output, or loss-of-signal output. In addition, GPIOB1, GPIOB2, and GPIOB3 can be used as a global I/O signal. The GPIO pins are independently configurable using the GPIOy*n*S fields of the [GLOBAL.GIOCR](#page-55-0) register. When a GPIO pin is configured as an input, its value can be read from the [GLOBAL.GIORR](#page-58-0) register. When a GPIO pin is configured as a loss-of-signal (LOS) status output, its state mimics the state of the [LINE.RSR](#page-80-0):RLOS status bit. When a port is powered down and a GPIO pin has been programmed as an associated loss-of-signal output, the pin is held low. Programming a GPIO pin as a global signal as shown in [Table 9-14](#page-41-0) overrides the I/O settings specified by the GPIOy*n*S field for that pin and configures the pin as an input or an output as shown in the Function column of [Table 9-14](#page-41-0).

### **Table 9-14. GPIO Pin Global Signal Assignments**

*Note: n = 1 to 4.* 

### <span id="page-42-0"></span>**Table 9-15. GPIO Pin Control**

*Note:*  $n = 1$  to 4,  $y = A$  or B.

### **9.7.4 Performance Monitor Register Update**

Each performance monitor counter can count at least one second of events before saturating at the maximum count. Each counter has an associated status bit that is set when the counter value is not zero, a latched status bit that is set when the counter value changes from zero to one, and a latched status bit that is set each time the counter is incremented.

There is a holding register for each performance monitor counter that is updated when a performance monitoring update is performed. A performance monitoring update causes the counter value to be loaded into the holding register and the counter to be cleared. If a counter increment occurs at the exact same time as the counter reset, the counter is loaded with a value of one, and the "counter is non-zero" latched status bit is set.

The Performance Monitor Update (PMU) signal initiates a performance monitoring update. The PMU signal can be sourced from a general-purpose I/O pin (GPIOB1), the internal one-second reference, a global register bit ([GLOBAL.CR1:](#page-53-0)GPMU), or a port register bit [\(PORT.CR1:](#page-60-0)PMU). **Note:** The BERT PMU can be sourced from a block level register bit [\(BERT.CR](#page-84-0):LPMU). To use GPIOB1, [GLOBAL.CR1](#page-53-0).GPM[1:0] is set to 01, the appropriate [PORT.CR1](#page-60-0):PMUM bits are set to 1, and the appropriate [BERT.CR:](#page-84-0)PMUM bits are set to 1. To use the internal one-second reference, [GLOBAL.CR1](#page-53-0):GPM[1:0] is set to 1X, the appropriate [PORT.CR1](#page-60-0):PMUM bits are set to 1, and the appropriate [BERT.CR:](#page-84-0)PMUM bits are set to 1. To use the global PMU register bit, [GLOBAL.CR1:](#page-53-0)GPM[1:0] is set to 00, the appropriate [PORT.CR1:](#page-60-0)PMUM bits are set to 1, and the appropriate [BERT.CR:](#page-84-0)PMUM bits are set to 1. To use the port PMU register bit, the associated [PORT.CR1:](#page-60-0)PMUM bit is set to 0, and the appropriate [BERT.CR](#page-84-0):PMUM bits are set to 1. To use the [BERT.CR:](#page-84-0)LPMU register bit, the appropriate [BERT.CR:](#page-84-0)PMUM bit is set to 0.

When using the global or port PMU register bits, the PMU bit should be set to initiate the process and cleared when the associated PMS status bit ([GLOBAL.SR](#page-57-0):GPMS or [PORT.SR:](#page-65-0)PMS) is set. When using the GPIO pin or internal one-second reference, the PMS bit is set shortly after the signal goes high, and cleared shortly after the signal goes low. The PMS has an associated latched status bit that can generate an interrupt if enabled. The port PMS signal does not go high until an update of all the appropriately configured block-level performance monitoring counters in the port has been completed. The global PMS signal does not go high until an update of all the appropriately configured port-level performance monitoring counters in the entire chip has been completed.

### **9.7.5 Transmit Manual Error Insertion**

Various types of errors can be inserted in the transmit data stream using the Transmit Manual Error Insertion (TMEI) signal, which can be sourced from a block-level register bit, a port register bit ([PORT.CR1](#page-60-0):TMEI), a global register bit [\(GLOBAL.CR1](#page-53-0):TMEI), or a general-purpose I/O pin (GPIOB2). To use GPIOB2 as the TMEI signal, [GLOBAL.CR1](#page-53-0).MEIMS is set to 1, the appropriate [PORT.CR1.](#page-60-0)MEIMS bits are set to 1, and the appropriate blocklevel MEIMS bits are set to 1. To use the global TMEI register bit, [GLOBAL.CR1.](#page-53-0)MEIMS is set to 0, the appropriate [PORT.CR1](#page-60-0).MEIMS bits are set to 1, and the appropriate block-level MEIMS bits are set to 1. To use the port TMEI register bit, the associated [PORT.CR1.](#page-60-0)MEIMS is set to 0 and the appropriate block-level MEIMS bits are set to 1. To use the block-level TSEI register bit, the associated block-level MEIMS bit is set to 0.

In order for an error of a particular type to be inserted, the error type must be enabled by setting the associated error insertion enable bit in the associated block's error insertion register. Once enabled, a single error is inserted at the next opportunity when the TMEI signal transitions from zero to one. **Note:** If the TMEI signal has multiple zero to one transitions between error insertion opportunities, only a single error is inserted.

### <span id="page-43-0"></span>**9.8 8-/16-Bit Parallel Microprocessor Interface**

See [Table 12-6](#page-98-0) and [Figure 12-3](#page-100-0) through [Figure 12-10](#page-103-0) for parallel interface timing diagrams and parameters.

PRELIMINARY

#### **9.8.1 8-Bit and 16-Bit Bus Widths**

When the [IFSEL](#page-17-0) pins are set to 1XX the device presents a parallel microprocessor interface. In 8-bit modes [\(IFSEL](#page-17-0)  $= 10X$ ), the address is composed of all the address bits including [A\[0\],](#page-19-0) the lower 8 data lines D[7:0] are used, and the upper 8 data lines D[15:8] are disabled (high impedance). In 16-bit modes ([IFSEL](#page-17-0) = 11X), the address does not include [A\[0\],](#page-19-0) and all 16 data lines [D\[15:0\]](#page-19-0) are used.

### **9.8.2 Byte Swap Mode**

In 16-bit modes [\(IFSEL](#page-17-0) = 11X) the microprocessor interface can operate in byte swap mode. The [BSWAP](#page-19-0) pin is used to determine whether byte swapping is enabled. This pin should be static and not change during operation. When the [BSWAP](#page-19-0) pin is low the upper register bits REG[15:8] are mapped to the upper external data bus lines D[15:8], and the lower register bits REG[7:0] are mapped to the lower external data bus lines [D](#page-19-0)[7:0]. When the [BSWAP](#page-19-0) pin is high the upper register bits REG[15:8] are mapped to the lower external data bus lines [D\[](#page-19-0)7:0], and the lower register bits REG[7:0] are mapped to the upper external data bus lines D[15:8].

#### **9.8.3 Read-Write and Data Strobe Modes**

The processor interface can operate in either read-write strobe mode (also known as "Intel" mode) or data strobe mode (also known as "Motorola" mode). When [IFSEL](#page-17-0) = 1X0 the read-write strobe mode is enabled. In this mode a negative pulse on  $\overline{RD}$  $\overline{RD}$  $\overline{RD}$  performs a read cycle, and a negative pulse on  $\overline{WR}$  $\overline{WR}$  $\overline{WR}$  performs a write cycle.

When [IFSEL](#page-17-0) = 1X1 the data strobe mode is enabled. In this mode a negative pulse on  $\overline{DS}$  $\overline{DS}$  $\overline{DS}$  when [R/W](#page-19-0) is high performs a read cycle, a negative pulse on  $\overline{DS}$  $\overline{DS}$  $\overline{DS}$  when [R/W](#page-19-0) is low performs a write cycle..

#### **9.8.4 Multiplexed and Nonmultiplexed Operation**

In all parallel interface modes the interface supports both multiplexed and nonmultiplexed operation. For multiplexed operation in 8-bit modes, wire [A](#page-19-0)[9:8] to the processor's A[9:8] pins, wire A[7:0] to [D\[](#page-19-0)7:0] and to the processor's multiplexed address/data bus, and connect the [ALE](#page-19-0) pin to the appropriate pin on the processor. For nonmultiplexed 8-bit operation, wire [ALE](#page-19-0) high and wire [A\[](#page-19-0)9:0] and [D\[](#page-19-0)7:0] to the appropriate pins on the processor.

For multiplexed operation in 16-bit modes, wire [A](#page-19-0)[9:0] to D[9:0], wire [D\[15:0\]](#page-19-0) to the CPU's multiplexed address/data bus, and connect the [ALE](#page-19-0) pin to the appropriate pin on the processor. For nonmultiplexed 16-bit operation, wire [ALE](#page-19-0) high and wire [A](#page-19-0)[9:0] and  $D[15:0]$  to the appropriate pins on the processor.

#### **9.8.5 Clear-On-Read and Clear-On-Write Modes**

The latched status register bits can be programmed to clear on a read access or clear on a write access. The global control register bit [GLOBAL.CR2.](#page-54-0)LSBCRE specifies the method used to clear all of the latched status registers. When LSBCRE = 0, latched status register bits are cleared when written with a 1. When LSBCRE = 1, latched status register bits are cleared when read.

The clear-on-write mode expects the user to use the following method: read the latched status register then write a 1 to the register bits to be cleared. This method is useful when multiple software tasks use the same latched status register. Each task can clear the bits it uses without affecting any of the latched status bits used by other tasks.

The clear-on-read mode clears all latched status bits in a register automatically when the latched status register is read. This method works well when no more than one software task uses any single latched status register. An event that occurs while the associated latched status register is being read results in the associated latched status bit being set after the read is completed.

### **9.8.6 Global Write Mode**

When [GLOBAL.CR2](#page-54-0):GWRM = 1, a write to a register of any port, including a port not present on the device, causes the data to be written to the same register in all the ports on the device. (On the DS32501 ports 2 through 4 are not present. On the DS32502 ports 3 through 4 are not present. On DS32503 port 4 is not present.) In this mode register reads are not supported and result in undefined data.

### **9.9 SPI Serial Microprocessor Interface**

When the [IFSEL](#page-17-0) pins are set to 01X the device presents an SPI interface on the  $\overline{CS}$  $\overline{CS}$  $\overline{CS}$ , [SCLK](#page-20-0), [SDI](#page-20-0), and [SDO](#page-20-0) pins. SPI is a widely-used master/slave bus protocol that allows a master device and one or more slave devices to communicate over a serial bus. The DS3250x is always a slave device. Masters are typically microprocessors, ASICs or FPGAs. Data transfers are always initiated by the master device, which also generates the [SCLK](#page-20-0) signal. The DS3250x receives serial data on the [SDI](#page-20-0) pin and transmits serial data on the [SDO](#page-20-0) pin. [SDO](#page-20-0) is highimpedance except when the DS3250x is transmitting data to the bus master. Note that the [ALE](#page-19-0) pin must be wired high for proper operation of the SPI interface.

PRELIMINARY

**Bit Order.** When [IFSEL\[2:0\]](#page-17-0) = 010 the register address and all data bytes are transmitted MSB first on both [SDI](#page-20-0) and [SDO.](#page-20-0) When [IFSEL\[2:0\]](#page-17-0) = 011, the register address and all data bytes are transmitted LSB first on both [SDI](#page-20-0) and [SDO.](#page-20-0) The Motorola SPI convention is MSB first.

**Clock Polarity and Phase.** The [CPOL](#page-20-0) pin defines the polarity of [SCLK.](#page-20-0) When [CPOL](#page-20-0) = 0, [SCLK](#page-20-0) is normally low and pulses high during bus transactions. When [CPOL](#page-20-0) = 1, [SCLK](#page-20-0) is normally high and pulses low during bus transactions. The [CPHA](#page-20-0) pin sets the phase (active edge) of [SCLK.](#page-20-0) When [CPHA](#page-20-0) = 0, data is latched in on [SDI](#page-20-0) on the leading edge of the [SCLK](#page-20-0) pulse and updated on [SDO](#page-20-0) on the trailing edge. When [CPHA](#page-20-0) = 1, data is latched in on SDI on the trailing edge of the [SCLK](#page-20-0) pulse and updated on [SDO](#page-20-0) on the following leading edge. See [Figure](#page-45-0)  [9-10.](#page-45-0)

**Device Selection.** Each SPI device has its own chip-select line. To select the DS3250x, pull its  $\overline{CS}$  $\overline{CS}$  $\overline{CS}$  pin low.

**Control Word.** After [CS](#page-19-0) is pulled low, the bus master transmits the control word during the first 16 [SCLK](#page-20-0) cycles. In MSB-first mode the control word has the form:

 $R/\overline{W}$  A13 A12 A11 A10 A9 A8 A7 A6 A5 A4 A3 A2 A1 A0 BURST

where A[13:0] is the register address, R $\overline{W}$  is the data direction bit (1 = read, 0 = write), and BURST is the burst bit (1 = burst access, 0 = single-byte access). In LSB-first mode the order of the 14 address bits is reversed. In the discussion that follows, a control word with R $\overline{W}$  = 1 is a read control word, while a control word with R $\overline{W}$  = 0 is a write control word. **Note:** The address range of the DS32504 is 000h–3FFh, therefore, A[13:10] are ignored.

**Single-Byte Writes.** See [Figure 9-11](#page-45-0). After [CS](#page-19-0) goes low, the bus master transmits a write control word with BURST = 0 followed by the data byte to be written. The bus master then terminates the transaction by pulling  $\overline{CS}$  $\overline{CS}$  $\overline{CS}$ high.

**Single-Byte Reads.** See [Figure 9-11.](#page-45-0) After [CS](#page-19-0) goes low, the bus master transmits a read control word with BURST = 0. The DS3250x then responds with the requested data byte. The bus master then terminates the transaction by pulling  $\overline{\text{CS}}$  $\overline{\text{CS}}$  $\overline{\text{CS}}$  high.

**Burst Writes.** See [Figure 9-11](#page-45-0). After  $\overline{CS}$  $\overline{CS}$  $\overline{CS}$  goes low, the bus master transmits a write control word with BURST = 1 followed by the first data byte to be written. The DS3250x receives the first data byte on [SDI](#page-20-0), writes it to the specified register, increments its internal address register, and prepares to receive the next data byte. If the master continues to transmit, the DS3250x continues to write the data received and increment its address counter. After the address counter reaches 3FFh it rolls over to address 000h and continues to increment.

**Burst Reads.** See [Figure 9-11](#page-45-0). After [CS](#page-19-0) goes low, the bus master transmits a read control word with BURST = 1. The DS3250x then responds with the requested data byte on [SDO,](#page-20-0) increments its address counter, and prefetches the next data byte. If the bus master continues to demand data, the DS3250x continues to provide the data on [SDO](#page-20-0), increment its address counter, and prefetch the following byte. After the address counter reaches 3FFh it rolls over to address 000h and continues to increment.

**Early Termination of Bus Transactions.** The bus master can terminate SPI bus transactions at any time by pulling  $\overline{CS}$  $\overline{CS}$  $\overline{CS}$  high. In response to early terminations, the DS3250x resets its SPI interface logic and waits for the start of the next transaction. If a write transaction is terminated prior to the [SCLK](#page-20-0) edge that latches the LSB of a data byte, the current data byte is not written.

**Design Option: Wiring SDI and SDO Together.** Because communication between the bus master and the DS3250x is half-duplex, the [SDI](#page-20-0) and [SDO](#page-20-0) pins can be wired together externally to reduce wire count. To support this option, the bus master must not drive the [SDI/SDO](#page-20-0) line when the DS3250x is transmitting.

**AC Timing.** See [Table 12-9](#page-104-0) and [Figure 12-11](#page-105-0) for AC timing specifications for the SPI interface.

### <span id="page-45-0"></span>**Figure 9-10. SPI Clock Polarity and Phase Options**

### **Figure 9-11. SPI Bus Transactions**

### <span id="page-46-0"></span>**9.10 Interrupt Structure**

The interrupt structure is designed to efficiently guide the user to the source of an interrupt. The status bits in the global interrupt status register ([GLOBAL.ISR](#page-56-0)) are read to determine if the interrupt source comes from a global event, such as a one-second timer interrupt, or one of the ports. If the interrupt source is a global event, the global status register is read [\(GLOBAL.SRL](#page-57-0)) to determine the source. If the interrupt source is a port, the port interrupt status register [\(PORT.ISR](#page-64-0)) is read to determine if the interrupt source comes from a port event, such as a performance monitor update interrupt, or one of the functional blocks inside the port. If the interrupt source is a port event, the port status register is read [\(PORT.SRL](#page-65-0)) to determine the source. If the interrupt source is from a functional block inside the port, the associated block's status register is read to determine the source. The source of an interrupt can be determined by reading no more than three 16-bit registers.

Once the interrupt source has been determined, the interrupt can be cleared by either reading or writing the latched status register (see Section [9.8.5](#page-43-0)). An alternate method for clearing an interrupt is to disable the interrupt at the bit, block, port, or global level by writing a zero to the associated interrupt enable bit. **Note:** Disabling the interrupt at the block, port, or global level disables *all* interrupts sources at or below that level.

### **Figure 9-12. Interrupt Signal Flow**

### <span id="page-47-0"></span>**9.11 Reset and Power-Down**

When the hardware interface is enabled ([IFSEL](#page-17-0) = 00X), the device can be reset via the  $\overline{\text{RST}}$  $\overline{\text{RST}}$  $\overline{\text{RST}}$  pin. The transmitters of all ports can be powered down using the [TPD](#page-18-0) pin, while the receivers of all ports can be powered down using the [RPD](#page-18-0) pin.

When a microprocessor interface is enabled ([IFSEL](#page-17-0)  $\neq$  00X), the device presents a number of reset and power-down options. The device can be reset at a global level via the [GLOBAL.CR1](#page-53-0):[RST](#page-17-0) bit or the  $\overline{\text{RST}}$  pin, and at the port level via the [PORT.CR1:](#page-60-0)RST bit. Each port can be powered down via the [PORT.CR1:](#page-60-0)TPD and RPD bits. The JTAG logic is reset by the [JTRST](#page-21-0) pin.

The external  $\overline{\text{RST}}$  $\overline{\text{RST}}$  $\overline{\text{RST}}$  pin and the global reset bit [\(GLOBAL.CR1](#page-53-0):RST) are combined to create an internal global reset signal. The global reset signal resets all the status and control registers on the chip (except the [GLOBAL.CR1:](#page-53-0)RST bit), to their default values. It also resets all flip-flops in the global logic (including the CLAD block) and port logic to their reset values. The [GLOBAL.CR1](#page-53-0):RST bit stays set after a one is written to it. It is reset to zero when a zero is written to it or when the external  $\overline{\text{RST}}$  $\overline{\text{RST}}$  $\overline{\text{RST}}$  pin is active.

At the port level, the global reset signal combines with the port reset bit ([PORT.CR1](#page-60-0):RST) to create a port reset signal. The port reset signal resets all the status and control registers in the port (except [PORT.CR1:](#page-60-0)RST bit) to their default values. It also resets all flip-flops in the port logic to their reset values. The port reset bit ([PORT.CR1](#page-60-0):RST) stays set after a one is written to it. It is reset to zero when a zero is written to it or when the global reset signal is active.

The data path reset (RSTDP) resets all of the same registers and flip-flops as the "general" reset (RST), except for the control registers. This allows the device to be programmed while the data path logic is in reset. It is recommended that a port be placed in data path reset during configuration changes.

The global data path reset bit [\(GLOBAL.CR1](#page-53-0):RSTDP) is set to one when the global reset signal is active. This bit is cleared when a zero is written to it while the global reset signal is inactive. The global data path reset resets all of the data path registers and flip-flops on the chip.

The port data path reset bit ([PORT.CR1](#page-60-0):RSTDP) is set to one when the port reset signal is active. It is cleared when a zero is written to it while the port reset signal is inactive. The port data path reset resets all of the port logic data path registers and flip-flops.

### **Table 9-16. Reset and Power-Down Sources**

*Register bit states: F0 = forced to 0, F1 = forced to 1, 0 = set to 0, 1 = set to 1.* 

The reset signals in the device are asserted asynchronously and do not require a clock to put the logic into the reset state. The control registers do not require a clock to come out of the reset state, but all other logic does require a clock to come out of the reset state.

### DS32501/DS32502/DS32503/DS32504 PRELIMINARY

The port transmit power-down function [\(PORT.CR1](#page-60-0):TPD) disables all of the transmit clocks and powers down the transmit LIU to minimize power consumption. The port receive power-down function ([PORT.CR1](#page-60-0):RPD) disables all of the receive clocks and powers down the receive LIU to minimize power consumption. The one-second timer circuit can be powered down by disabling its reference clock. The CLAD can be powered down by disabling it (setting [GLOBAL.CR2:](#page-54-0)CLAD[6:0] = 0). The global logic cannot be powered down.

After a global reset, all of the control and status registers in all ports are set to their default values and all the other flip-flops are reset to their reset values. The global data path reset ([GLOBAL.CR1:](#page-53-0)RSTDP), all the port data path resets [\(PORT.CR1](#page-60-0):RSTDP), and all the port power-down [\(PORT.CR1:](#page-60-0)TPD and RPD) bits are set after the global reset. A valid initialization sequence is to clear the port power-down bits in the ports that are to be active, write to all of the configuration registers to set them in the desired modes, then clear the [GLOBAL.CR1](#page-53-0):RSTDP and [PORT.CR1](#page-60-0):RSTDP bits. This causes all the logic to start up in a predictable manner. The device can also be initialized by clearing the [GLOBAL.CR1:](#page-53-0)RSTDP, [PORT.CR1](#page-60-0):RSTDP, and PORT.CR1:TPD and RPD bits, then writing to all of the configuration registers to set them in the desired modes, and then clearing all of the latched status bits. This second initialization scheme can cause the device to operate unpredictably for a brief period of time.

Some of the I/O pins are put into a known state at reset. At the global level, the microprocessor interface output and I/O pins ( $D[15:0]$ ) are forced into the high impedance state when the  $\overline{RST}$  $\overline{RST}$  $\overline{RST}$  pin is active, but not when the [GLOBAL.CR1](#page-53-0):RST bit is active. The CLAD clock pins [CLKA,](#page-20-0) [CLKB,](#page-20-0) and [CLKC](#page-20-0) are forced to be the LIU reference clock inputs. The general-purpose I/O pins [\(GPIOAn](#page-19-0) & [GPIOBn\)](#page-19-0) are forced to be inputs until after the [RST](#page-17-0) pin is deasserted. At the port level, the LIU transmitter outputs [TXP](#page-16-0) and [TXN](#page-16-0) are forced into a high impedance state.

**Note:** Setting any of the reset (RST), data path reset (RSTDP), or power-down (TPD, RPD) bits for less than 100ns can result in the associated circuits coming up in a random state. When a power-down bit is cleared, it takes approximately 1ms for all the associated circuits to power-up.

### **10. REGISTER MAPS AND DESCRIPTIONS**

### **10.1 Overview**

When a microprocessor interface is enabled [\(IFSEL\[2:0\]](#page-17-0)  $\neq$  00X), the registers described in this section are accessible. The overall memory map is shown in [Table 10-1.](#page-50-0) The DS32504 register map covers the address range of 000 to 3FFh. Address line [A\[](#page-19-0)9] is not present on the DS32503 and DS32502. On the DS32502, writes into the address space for LIU3 are ignored, and reads from these addresses return 00h. On the DS32501, address lines [A](#page-19-0)[9:8] are not present, and writes into the address space for LIU[2:4] are ignored, and reads from these addresses return 00h. The address LSB [A\[0\]](#page-19-0) is used to address the upper and lower bytes of a register in 8-bit mode, and to swap the upper and lower bytes in 16-bit mode.

In each register, bit 15 is the MSB and bit 0 is the LSB. *Register addresses not listed and bits marked "—" are reserved and must be written with 0 and ignored when read*. Writing other values to these registers may put the device in a factory test mode resulting in undefined operation. Bits labeled "0" or "1" must be written with that value for proper operation. Register fields with underlined names are read-only fields; writes to these fields have no effect. All other fields are read-write. Register fields are described in detail in the register descriptions in Sections [10.3](#page-51-0) through [10.8.](#page-83-0)

### **10.1.1 Status Bits**

The device has two types of status bits. Real-time status bits are read-only and indicate the state of a signal at the time it is read. Latched status bit are set when the associated event occurs and remain set until cleared. Once cleared, a latched status bit is not set again until the associated event recurs (goes away and comes back). A latched-on-change bit is a latched status bit that is set when the event occurs and when it goes away. A latched status bit can be cleared using either a clear-on-read or clear-on-write method (see Section [9.8.5](#page-43-0)). For clear-onread, all latched status bits in a latched status register are cleared when the register is read. In 16-bit mode, all 16 latched status bits are cleared. In 8-bit mode, only the eight bits read are cleared. For clear-on-write, a latched bit in a latched status register is cleared when a logic 1 is written to that bit. For example, writing FFFFh to a 16-bit latched status register clears all latched status bits in the register, whereas writing 0001h only clears bit 0 of the register. When set, some latched status bits can cause an interrupt request if enabled to do so by corresponding interrupt enable bits.

### **10.1.2 Configuration Fields**

Configuration fields are read-write. During reset, each configuration field reverts to the default value shown in the register definition. *Configuration register bits marked "—" are reserved and must be written with 0.* Configuration registers and bits can be written to and read from during a data path reset, however, all changes to these bits are ignored during the data path reset. As a result, all bits requiring a 0 to 1 transition to initiate an action must have the transition occur after the data path reset has been removed. See Section [9.11](#page-47-0) for more information about resets and data path resets.

### **10.1.3 Counters**

All counters stop counting at their maximum count. A counter register is updated by asserting (low to high transition) the performance monitoring update signal (PMU). During a counter register update, the performance monitoring status signal (PMS) is deasserted. A counter register update consists of loading the counter register with the current count, resetting the counter, resetting the zero count status indication, and then asserting PMS. No events are missed during an update. See Section [9.7.4](#page-42-0) for more information about performance monitor register updates.

### <span id="page-50-0"></span>**10.2 Overall Register Map**

### **Table 10-1. Overall Register Map**

### **Table 10-2. Port Registers**

*Note: The address offsets given in this table are offsets from port base addresses shown in [Table 10-1](#page-50-0).*

## <span id="page-51-0"></span>**10.3 Global Registers**

## **Table 10-3. Global Register Map**

<span id="page-52-0"></span>

**Bits 15 to 12: Device REV ID (ID[15:12]).** These bits of the device ID register have the same information as the four bits of the JTAG REV ID portion of the JTAG ID register, JTAG ID[31:28]. See Section [11](#page-92-0).

**Bits 11 to 0: Device CODE ID (ID[11:0]).** These bits of the device ID register have the same information as the 12 bits of the JTAG CODE ID portion of the JTAG ID register, JTAG ID[23:12]. See Section [11.](#page-92-0)

<span id="page-53-0"></span>

Register Name: **GLOBAL.CR1 Global Control Register 1** Register Address: **002h** 

**Bits 11 to 9: Global One-Second Reference Source (G1SRS[2:0]).** These bits determine the source for the internally generated one-second reference. The source is selected from one of the CLAD clocks or from one of the port transmit clocks. See Section [9.7.2](#page-41-0).

**Bit 8: Global One-Second Reference Output Enable (G1SROE).** This bit determines whether the GPIOB3 pin is used to output the global one-second reference signal. See Section [9.7.2](#page-41-0).

0 = GPIOB3 pin mode selected by [GLOBAL.GIOCR:](#page-55-0)GIOB3S[1:0]

1 = GPIOB3 outputs the global one-second reference signal specified by [GLOBAL.CR1](#page-53-0):G1SRS[2:0]

**Bit 7: Transmit Manual Error Insert (TMEI).** When [GLOBAL.CR1:](#page-53-0)MEIMS = 0, this bit is used to insert errors in all blocks in all ports where block level MEIMS = 1 and [PORT.CR1:](#page-60-0)MEIMS = 1. Error(s) are inserted at the next opportunity after this bit transitions from low to high. See Section [9.7.5.](#page-42-0) **Note:** This bit should be set low immediately after each error insertion.

**Bit 6: Manual Error Insert Mode Select (MEIMS).** This bit specifies the source of the manual error insertion signal for all block-level error generators that have block-level MEIMS = 1 and [PORT.CR1](#page-60-0):MEIMS = 1. See Section [9.7.5](#page-42-0).

- 0 = Global error insertion using [GLOBAL.CR1:](#page-53-0)TMEI bit
- 1 = Global error insertion using the GPIOB2 pin

**Bits 5 and 4: Global Performance Monitor Update Mode (GPM[1:0]).** These bits specify the source of the performance monitoring update signal for all blocks that have block-level PMUM = 1 and [PORT.CR1:](#page-60-0)PMUM = 1. See Section [9.7.4.](#page-42-0)

- 00 = Global PM update using the [GLOBAL.CR1](#page-53-0):GPMU bit
- 01 = Global PM update using the GPIOB1 pin
- 1X = One-second PM update using the internal one-second counter (see Section [9.7.2](#page-41-0))

**Bit 3: Global Performance Monitor Register Update (GPMU).** When [GLOBAL.CR1:](#page-53-0)GPM[1:0] = 00, this bit is used to update all of the performance monitor registers where block-level PMUM = 1 and [PORT.CR1:](#page-60-0)PMUM = 1. When this bit transitions from low to high, all configured performance monitoring registers are updated with the latest counter value, and all associated counters are reset. This bit should remain high until the performance monitor update status bit ([GLOBAL.SR](#page-57-0):GPMS) goes high, and then it should be brought back low, which clears the GPMS status bit. If a counter increment occurs at the exact same time as the counter reset, the counter is loaded with a value of one, and the "counter is non-zero" latched status bit is set. See Section [9.7.4.](#page-42-0)

**Bit 1: Reset Data Path (RSTDP).** When this bit is set, it forces all of the internal data path and status registers in all ports to their default state. This bit must be set high for a minimum of 100ns. See Section [9.11.](#page-47-0)

0 = Normal operation

1 = Force all data path registers to their default values

**Bit 0: Reset (RST).** When this bit is set, all of the internal data path and status and control registers (except this RST bit), on all of the ports, are reset to their default state. This bit must be set high for a minimum of 100ns. This bit is logically ORed with the inverted hardware signal [RST](#page-17-0). See Section [9.11](#page-47-0).

0 = Normal operation

1 = Force all internal registers to their default values

<span id="page-54-0"></span>Register Name: **GLOBAL.CR2**  Register Address: **004h** 

**Global Control Register 2** 

**Bits 14 to 8: CLAD I/O Mode (CLAD[6:0]).** These bits control the CLAD clock I/O pins [REFCLK](#page-20-0), [CLKA,](#page-20-0) [CLKB,](#page-20-0) [CLKC](#page-20-0) and [CLKD](#page-20-0). See [Table 9-11](#page-40-0) and [Table 9-12](#page-40-0) in Section [9.7.1](#page-39-0).

**Bit 5: CLKD Frequency is 19.44MHz (CLKD19).** This bit specifies the frequency to be output on CLKD when the CLAD[3] configuration bit is high.

- $0 = 77.76$ MHz
- $1 = 19.44$ MHz

**Bit 4:** INT **pin mode (INTM).** This bit determines the inactive mode of the [INT](#page-19-0) pin. The [INT](#page-19-0) pin always drives low when an enabled interrupt source is active. See Section [9.10.](#page-46-0)

0 = Pin is high impedance when no enabled interrupts are active

1 = Pin drives high when no enabled interrupts are active

**Bit 1: Latched Status Bit Clear on Read Enable (LSBCRE).** This bit determines when the latched status register bits are cleared. See Section [9.8.5](#page-43-0).

0 = Latched status register bits are cleared on a write

1 = Latched status register bits are cleared on a read

**Bit 0: Global Write Mode (GWRM).** This bit enables the global write mode. When this bit is set, a write to a register of any port causes a write to the same register in all the ports. In this mode register reads are not supported and result in undefined data. See Section [9.8.6.](#page-43-0)

- 0 = Normal write mode
- 1 = Global write mode

<span id="page-55-0"></span>Register Name: **GLOBAL.GIOCR**  Register Address: **010h** 

Register Description: **General-Purpose I/O Control Register** 

*Note: See Section [9.7.3](#page-41-0) for more information.* 

**Bits 15 and 14: General-Purpose I/O A4 Select (GIOA4S[1:0]).** These bits specify the function of the GPIOA4 pin.

 $00 =$  Input

01 = Output LOS status from port 4

 $10 =$  Output logic 0

11 = Output  $logic 1$ 

**Bits 13 and 12: General-Purpose I/O A3 Select (GIOA3S[1:0]).** These bits specify the function of the GPIOA3 pin.

 $00 =$  Input

01 = Output LOS status from port 3

- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 11 and 10: General-Purpose I/O A2 Select (GIOA2S[1:0]).** These bits specify the function of the GPIOA2 pin.

- $00 =$  Input
- 01 = Output LOS status from port 2
- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 9 and 8: General-Purpose I/O A1 Select (GIOA1S[1:0]).** These bits specify the function of the GPIOA1 pin.

- $00 =$  Input
- 01 = Output LOS status from port 1
- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 7 and 6: General-Purpose I/O B4 Select (GIOB4S[1:0]).** These bits specify the function of the GPIOB4 pin.

- $00 =$  Input
- 01 = Output LOS status from port 4
- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 5 and 4: General-Purpose I/O B3 Select (GIOB3S[1:0]).** These bits specify the function of the GPIOB3 pin. **Note:** If [GLOBAL.CR1:](#page-53-0)G1SROE is set to 1, GPIOB3 is the global one-second reference output signal.

- $00 =$  Input
- 01 = Output LOS status from port 3
- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 3 and 2: General-Purpose I/O B2 Select (GIOB2S[1:0]).** These bits specify the function of the GPIOB2 pin. **Note:** If [GLOBAL.CR1:](#page-53-0)MEIMS is set to 1, GPIOB2 is the global transmit manual error insertion (TMEI) input signal.

- $00 =$  Input
- 01 = Output LOS status from port 2
- $10 =$  Output logic 0
- $11 =$  Output logic 1

**Bits 1 and 0: General-Purpose I/O B1 Select (GIOB1S[1:0]).** These bits specify the function of the GPIOB1 pin. **Note:** If [GLOBAL.CR1:](#page-53-0)GPM[1:0] is set to 01, GPIOB1 is the global performance monitoring update input signal.

 $00 =$  Input

- 01 = Output LOS status from port 1
- $10 =$  Output logic 0
- $11 =$  Output logic 1

<span id="page-56-0"></span>

**Bits 4 to 1: Port n Interrupt Status Register (PnISR).** This bit is set when any of the bits in the port n interrupt status register [\(PORT.ISR\)](#page-64-0) are set and enabled for interrupt. When set, this bit causes an interrupt if [GLOBAL.ISRIE](#page-56-0):PnISRIE is set. See Section [9.10.](#page-46-0)

**Bit 0: Global Status Register (GSR).** This bit is set when any of the latched status register bits in the global latched status register [\(GLOBAL.SRL](#page-57-0)) are set and enabled for interrupt. When set, this bit causes an interrupt if [GLOBAL.ISRIE:](#page-56-0)GSRIE is set. See Section [9.10.](#page-46-0)

**Bits 4 to 1: Port n Interrupt Status Register Interrupt Enable (PnISRIE).** This bit is the interrupt enable for the [GLOBAL.ISR:](#page-56-0)PnISR status bit. See Section [9.10](#page-46-0).

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Global Status Register Interrupt Enable (GSRIE).** This bit is the interrupt enable for the [GLOBAL.ISR:](#page-56-0)GSR status bit. See Section [9.10](#page-46-0).

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

<span id="page-57-0"></span>

**Bit 2: CLAD Loss of Lock (CLOL).** This bit is set when the CLAD is not locked to the reference frequency.

**Bit 0: Global Performance Monitoring Update Status (GPMS).** This bit is set when the [PORT.SR](#page-65-0):PMS status bits are set in all of the ports that are enabled for global update control (i.e., all ports that have [PORT.CR1:](#page-60-0)PMUM = 1). Ports that have [PORT.CR1:](#page-60-0)PMUM = 0 have no effect on this bit. In global software update mode, the global update request bit ([GLOBAL.CR1](#page-53-0):GPMU) should be held high until this status bit goes high. See Section [9.7.4.](#page-42-0)

0 = The associated update request signal is low or not all register updates are completed

1 = The requested performance register updates are all completed

**Bit 6: CLAD C Clock Activity Latched (CLKCL).** This bit is set when the signal on the [CLKC](#page-20-0) pin is active. **Note:** This bit should always be low when [GLOBAL.CR2:](#page-54-0)CLAD[6:4]  $\neq$  000. See Section [9.7.1.](#page-39-0)

**Bit 5: CLAD B Clock Activity Latched (CLKBL).** This bit is set when the signal on the [CLKB](#page-20-0) pin is active. **Note:** This bit should always be low when [GLOBAL.CR2:](#page-54-0)CLAD[6:4]  $\neq$  000. See Section [9.7.1.](#page-39-0)

**Bit 4: CLAD A Clock Activity Latched (CLKAL).** This bit is set when the signal on the [CLKA](#page-20-0) pin is active. **Note:** This bit should always be low when [GLOBAL.CR2:](#page-54-0)CLAD[6:4]  $\neq$  000. See Section [9.7.1.](#page-39-0)

**Bit 3: CLAD Reference Clock Activity Status Latched (CLADL).** This bit is set when the CLAD PLL reference clock signal on the [REFCLK](#page-20-0) pin is active. **Note:** When [GLOBAL.CR2:](#page-54-0)CLAD[6:4] = 000, the [REFCLK](#page-20-0) pin is unused. See Section [9.7.1.](#page-39-0)

**Bit 2: CLAD Loss of Lock Latched (CLOLL).** This bit is set when the [GLOBAL.SR](#page-57-0):CLOL status bit transitions from low to high.

**Bit 1: Global One-Second Reference Status Latched (G1SREFL).** This bit is set once each second when the internal global one-second timer signal transitions low to high. When set, this bit causes an interrupt if interrupt enables [GLOBAL.SRIE](#page-58-0):G1SREFIE and [GLOBAL.ISRIE:](#page-56-0)GSRIE are both set. See Section [9.7.1.](#page-39-0)

**Bit 0: Global Performance Monitoring Update Status Latched (GPMSL).** This bit is set when the [GLOBAL.SR:](#page-57-0)GPMS status bit changes from low to high. When set, this bit causes an interrupt if interrupt enables [GLOBAL.SRIE:](#page-58-0)GPMSIE and [GLOBAL.ISRIE](#page-56-0):GSRIE are both set. See Section [9.7.1.](#page-39-0)

<span id="page-58-0"></span>Register Name: **GLOBAL.SRIE**  Register Address: **02Ch** 

**Global Status Register Interrupt Enable** 

**Bit 2: CLAD Loss of Lock Interrupt Enable (CLOLIE).** This bit is the interrupt enable for the [GLOBAL.SRL:](#page-57-0)CLOLL bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

### **Bit 1: Global One-Second Reference Interrupt Enable (G1SREFIE).** This bit is the interrupt enable for the

[GLOBAL.SRL:](#page-57-0)G1SREFL bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Global Performance Monitoring Update Status Interrupt Enable (GPMSIE).** This bit is the interrupt enable for the [GLOBAL.SRL](#page-57-0): GPMSL bit.

0 = mask the interrupt

 $1$  = enable the interrupt

**Bits 7 to 4: General-Purpose I/O A***n* **Status (GPIOA***n***).** Indicates the status of general-purpose I/O pin A*n* (GPIOA*n*). See Section [9.7.3.](#page-41-0)

**Bits 3 to 0: General-Purpose I/O B***n* **Status (GPIOB***n***).** Indicates the status of general-purpose I/O pin B*n* (GPIOB*n*). See Section [9.7.3.](#page-41-0)

## <span id="page-59-0"></span>**10.4 Port Common Registers**

### **Table 10-4. Port Common Register Map**

<span id="page-60-0"></span>**Register Name: PORT.CR1**<br> **Register Description: Port Contr** Register Address: **n x 80h + 00h** 

**Port Control Register 1** 

**Bit 7: Transmit Manual Error Insert (TMEI).** When [PORT.CR1](#page-60-0):MEIMS = 0, this bit is used to insert errors in all blocks where block-level MEIMS = 1. Error(s) are inserted at the next opportunity after this bit transitions from low to high. See Section [9.7.5.](#page-42-0) **Note:** This bit should be set low immediately after each error insertion.

**Bit 6: Transmit Manual Error Insert Mode Select (MEIMS).** This bit specifies the source of the error insertion signal for all block-level error generators that have block-level MEIMS = 1. See Section [9.7.5.](#page-42-0)

0 = Port-level error insertion via [PORT.CR1](#page-60-0):TMEI

1 = Global error insertion as specified by [GLOBAL.CR1](#page-53-0):MEIMS

**Bit 5: Port Performance Monitor Update Mode (PMUM).** This bit specifies the source of the performance monitoring update signal for all blocks that have block-level PMUM = 1. See Section [9.7.4.](#page-42-0)

- 0 = Port-level PM update via [PORT.CR1:](#page-60-0)PMU
- 1 = Global PM update as specified by [GLOBAL.CR1](#page-53-0):GPM[1:0]

**Bit 4: Port Performance Monitor Register Update (PMU).** When [PORT.CR1](#page-60-0):PMUM = 0, this bit is used to update all of the performance monitor registers where block-level PMUM = 1. When this bit transitions from low to high, all configured performance monitoring registers are updated with the latest counter values, and all associated counters are reset. This bit should remain high until the performance monitor update status bit ([PORT.SR:](#page-65-0)PMS) goes high, and then it should be brought back low, which clears the PMS status bit. If a counter increment occurs at the exact same time as the counter reset, the counter is loaded with a value of one, and the "counter is non-zero" latched status bit is set. See Section [9.7.4](#page-42-0).

**Bit 3: Transmit Power-Down (TPD).** When this bit is set, the transmit path of the port is powered down and considered "out of service". The digital logic is powered down by stopping the clocks. See Section [9.11](#page-47-0).

0 = Normal operation

1 = Power down the port transmit path  $(TXP)$  and  $TXN$  become high impedance)

**Bit 2: Receive Power-Down (RPD).** When this bit is set, the receive path of the port is powered down and considered "out of service". The digital logic is powered down by stopping the clocks. See Section [9.11](#page-47-0).

- 0 = Normal operation
- 1 = Power down the port receive path ([RPOS/RDAT](#page-16-0), [RNEG/RLCV,](#page-16-0) and [RCLK](#page-16-0) become high impedance)

**Bit 1: Reset Data Path (RSTDP).** When this bit is set, it forces all of the port's internal data path and status registers to their default state. This bit must be set high for a minimum of 100ns and then set back low. See Section [9.11.](#page-47-0)

- 0 = Normal operation
- 1 = Force all data path registers to their default values

**Bit 0: Reset (RST).** When this bit is set, all of the internal data path and status and control registers (except this RST bit) of this port are reset to their default state. This bit must be set high for a minimum of 100ns. This bit is logically ORed with the inverted hardware signal [RST](#page-17-0) and the [GLOBAL.CR1](#page-53-0):RST bit. See Section [9.11.](#page-47-0)

0 = Normal operation

1 = Force all internal registers to their default values

<span id="page-61-0"></span>Register Name: **PORT.CR2**  Register Address: **n x 80h + 02h** 

**Port Control Register 2** 

**Bits 7 and 6: LIU Mode (LM[1:0]).** These bits select the operating mode of the port. See Section [9.1.](#page-22-0)

 $00 = DS3$ 

 $01 = E3$ 

 $10 = STS-1$ 

 $11 =$  reserved

**Bit 4: Receive Output Disable (ROD).** See Section [9.3.6.4](#page-31-0).

 $0 =$  enable the receiver outputs

1 = disable the receiver outputs ([RCLK, RPOS](#page-16-0)/[RDAT](#page-16-0) and [RNEG](#page-16-0)/[RLCV](#page-16-0))

### **Bit 3: Transmit Binary Interface Enable (TBIN).** See Section [9.2.2.](#page-22-0)

- 0 = Transmitter framer interface is bipolar on the TPOS and TNEG pins. The B3ZS/HDB3 encoder is disabled.
- 1 = Transmitter framer interface is binary on the TDAT pin. The B3ZS/HDB3 encoder is enabled.

### **Bit 2: Receive Binary Interface Enable (RBIN).** See Section [9.3.6](#page-30-0).

- 0 = Receiver framer interface is bipolar on the RPOS and RNEG pins. The B3ZS/HDB3 decoder is disabled.
- 1 = Receiver framer interface is binary on the RDAT pin with the RLCV pin indicating line-code violations. The B3ZS/HDB3 encoder is enabled.

### **Bit 1: Transmit Common Clock Mode (TCC).** See Section [9.2.1.1](#page-22-0).

- 0 = Source transmit clock for port n from [TCLKn](#page-16-0)
- 1 = Source transmit clock for port n from TCLK1

<span id="page-62-0"></span>Register Name: **PORT.CR3**  Register Address: **n x 80h + 04h** 

Register Description: **Port Control Register 3** 

### **Bit 9: BERT Enable (BERTE).** See Section [9.5.](#page-35-0)

 $0 =$  disable the BERT pattern generator (the pattern detector is always enabled)

1 = enable the BERT pattern generator (the pattern detector is always enabled)

### **Bit 8: BERT Direction (BERTD).** See Section [9.5.](#page-35-0)

0 = line direction (transmit to receive)

1 = system direction (receive to transmit)

**Bit 7: STS-1 Scrambling Disable (SCRD).** This bit controls STS-1 scrambling when AIS-L is generated in STS-1 mode. See Section [9.2.4.](#page-23-0)

0 = Perform scrambling

1 = Do not perform scrambling

#### **Bit 4: AIS Type (AIST).** See Section [9.2.4](#page-23-0).

0 = Unframed all ones

1 = Framed DS3 AIS (DS3 mode), unframed all ones (E3 mode), or AIS-L (STS-1 mode)

**Bit 3: Transmit AIS (TAIS).** The type of AIS signal depends on the LIU mode (DS3, E3 or STS-1) and the configured AIS type. See Section [9.2.4.](#page-23-0)

0 = transmit normal data

1 = transmit AIS signal

**Bit 2: Loopback Select (LBS).** This bit affects the function of the Loopback Mode (LBM[1:0]) bits below.

**Bits 1 and 0: Loopback Mode (LB[1:0]).** These bits enable loopbacks. The effect of the LB = 11 decode is controlled by the LBS configuration bit. See Section [9.6](#page-39-0).

00 = No loopback 01 = Diagnostic Loopback (DLB) 10 = Line Loopback (LLB) 11 (LBS = 0) = Line Loopback (LLB) and Diagnostic Loopback (DLB) simultaneously 11 (LBS = 1) = Analog Loopback (ALB)

<span id="page-63-0"></span>Register Name: **PORT.INV Register Address:** 

Register Description: **Port I/O Invert Control Register** 

**Bit 6: [TNEG](#page-16-0) Invert (TNEGI).** This bit inverts the TNEG input pin when set.

0 = Noninverted

 $1 =$  Inverted

**Bit 5: [TPOS/TDAT](#page-16-0) Invert (TPOSI).** This bit inverts the **TPOS/TDAT** input pin when set.

0 = Noninverted

 $1 =$  Inverted

**Bit 4: [TCLK](#page-16-0) Invert (TCLKI).** This bit inverts the TCLK pin input pin when set. See Section [9.2.1.](#page-22-0)

0 = Noninverted; [TPOS/TDAT](#page-16-0) and [TNEG](#page-16-0) are sampled on the rising edge of [TCLK](#page-16-0). 1 = Inverted; [TPOS](#page-16-0)/[TDAT](#page-16-0) and [TNEG](#page-16-0) are sampled on the falling edge of [TCLK.](#page-16-0)

**Bit 2: [RNEG/RLCV](#page-16-0) Invert (RNEGI).** This bit inverts the RNEG/RLCV output pin when set.

0 = Noninverted

 $1 =$  Inverted

**Bit 1: RPOS/RDAT Invert (RPOSI).** This bit inverts the [RPOS/RDAT](#page-16-0) output pin when set.

0 = Noninverted

 $1 =$  Inverted

**Bit 0: RCLK Invert (RCLKI).** This bit inverts the RCLKn output pin when set. See Section [9.3.6.3.](#page-31-0)

0 = Noninverted; [RPOS/RDAT](#page-16-0) and [RNEG](#page-16-0)/[RLCV](#page-16-0) are updated on the falling edge of [RCLK](#page-16-0).

1 = Inverted; [RPOS](#page-16-0)/[RDAT](#page-16-0) and [RNEG](#page-16-0)/[RLCV](#page-16-0) are updated on the rising edge of [RCLK](#page-16-0).

<span id="page-64-0"></span>

**Bit 3: Line Decoder Status Register Interrupt Status (LDSR).** This bit is set when any of the latched status register bits in the B3ZS/HDB3 Line Decoder block are set and enabled for interrupt. When set, this bit causes an interrupt if [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are both set. See Section [9.10](#page-46-0).

**Bit 2: LIU Status Register Interrupt Status (LIUSR).** This bit is set when any of the latched status register bits in the LIU block are set and enabled for interrupt. When set, this bit causes an interrupt if [PORT.ISRIE](#page-64-0):LIUSRIE and [GLOBAL.ISRIE:](#page-56-0) PnISRIE are both set. See Section [9.10](#page-46-0).

**Bit 1: BERT Status Register Interrupt Status (BSR).** This bit is set when any of the latched status register bits in the BERT block are set and enabled for interrupt. When set, this bit causes an interrupt if [PORT.ISRIE:](#page-64-0)BSRIE and [GLOBAL.ISRIE:](#page-56-0) PnISRIE are both set. See Section [9.10](#page-46-0).

**Bit 0: Port Status Register Interrupt Status (PSR).** This bit is set when any of the latched status register bits in the port latched status register ([PORT.SRL](#page-65-0)) are set and enabled for interrupt. When set, this bit causes an interrupt if [PORT.ISRIE](#page-64-0):PSRIE and [GLOBAL.ISRIE:](#page-56-0) PnISRIE are both set. See Section [9.10](#page-46-0).

**Bit 3: Line Decoder Status Register Interrupt Enable (LDSRIE).** This bit is the interrupt enable for the [PORT.ISR](#page-64-0):LDSR status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 2: LIU Status Register Interrupt Enable (LIUSRIE).** This bit is the interrupt enable for the [PORT.ISR](#page-64-0):LIUSR status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 1: BERT Status Register Interrupt Enable (BSRIE).** This bit is the interrupt enable for the [PORT.ISR](#page-64-0):BSR status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Port Status Register Interrupt Enable (PSRIE).** This bit is the interrupt enable for the [PORT.ISR](#page-64-0):PSR status bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

**Bit 15: Spare 1 Status Bit (SPR1).** This bit is a spare status bit reserved for future use. It indicates the current value of the [PORT.CR1](#page-60-0).SPARE1 bit. **Note:** The default value is the same as [PORT.CR1.](#page-60-0)SPARE1.

**Bit 7: Spare 2 Status Bit (SPR2).** This bit is a spare status bit reserved for future use. It indicates the current value of the [PORT.CR2](#page-61-0).SPARE2 bit. **Note:** The default value is the same as [PORT.CR2.](#page-61-0)SPARE2.

**Bit 0: Performance Monitoring Update Status (PMS).** This bit is set when the PMS bits are set in all of the port functional blocks that are configured for port-level update control (i.e., all blocks that have PMUM = 1). Blocks that have PMUM = 0 have no effect on this bit. In port-level software update mode, the port update request bit [\(PORT.CR1](#page-60-0):PMU) should be held high until this status bit goes high. See Section [9.7.4](#page-42-0).

0 = The associated update request signal is low or not all register updates are completed

1 = The requested performance register updates are all completed

<span id="page-65-0"></span>Register Name: **PORT.SR** 

**Bit 8: Transmit Clock Activity Status Latched (TCLKL).** This bit is set when the signal on the TCLK pin for this port is active. When set, this bit causes an interrupt if interrupt enables [PORT.SRIE:](#page-66-0)TCLKIE, [PORT.ISRIE](#page-64-0):PSRIE and [GLOBAL.ISRIE:](#page-56-0) PnISRIE are all set.

**Bit 0: Performance Monitoring Update Status Latched (PMSL).** This bit is set when the [PORT.SR:](#page-65-0)PMS status bit changes from low to high. When set, this bit causes an interrupt if interrupt enables [PORT.SRIE](#page-66-0):PMSIE, [PORT.ISRIE](#page-64-0):PSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.7.4](#page-42-0).

<span id="page-66-0"></span>Register Name: **PORT.SRIE**  Register Address: **n x 80h + 1Ch** 

**Port Status Register Interrupt Enable** 

**Bit 8: Transmit Clock Activity Latched Status Interrupt Enable (TCLKIE).** This bit is the interrupt enable for the [PORT.SRL:](#page-65-0)TCLKL bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 7: Spare 2 Latched Status Interrupt Enable (SPR2IE).** This bit is the interrupt enable for the [PORT.SRL:](#page-65-0)SPR2L bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Performance Monitoring Update Latched Status Interrupt Enable (PMSIE).** This bit is the interrupt enable for the [PORT.SRL:](#page-65-0)PMSL bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

## <span id="page-67-0"></span>**10.5 LIU Registers**

## **Table 10-5. LIU Register Map**

<span id="page-68-0"></span>

**Bits 11 and 10: Jitter Attenuator Depth (JAD[1:0]).** These bits select the jitter attenuator buffer depth. See Section [9.4.](#page-34-0)

- $00 = 16$  bits
- $01 = 32$  bits
- $10 = 64$  bits
- $11 = 128$  bits

**Bits 9 and 8: Jitter Attenuator Select (JAS[1:0]).** These bits select the location of the jitter attenuator. See Section [9.4](#page-34-0).

- $00 = Disabled$
- 01 = Receive Path
- 10 = Transmit Path
- 11 = Transmit Path

**Bit 5: Transmit LIU LBO (TLBO).** This bit is used to enable the transmit LBO circuit which causes the transmit signal to be preattenuated to mimic the attenuation of approximately approximates about 225 feet of cable. This is used to reduce near end cross talk when the cable lengths are short. This signal is only valid in DS3 and STS-1 modes. See Section [9.2.6.](#page-26-0)

- 0 = Disabled
- $1$  = Enabled

**Bit 4: Transmit Output Enable (TOE).** This bit enables the transmitter outputs (TXP and TXN). The transmitter continues to operate internally when the transmitter is tri-stated. Only the line driver and driver monitor are disabled. See Section [9.2.7.](#page-27-0) **Note:** This bit is ORed with the associated TOE input pin.

0 = TXP and TXN are high impedance

1 = TXP and TXN are driven

**Bit 3: Transmit Termination Resistor Enable (TTRE).** This bit indicates when the transmitter internal termination is enabled. See Section [9.2.8](#page-27-0).

- 0 = Disabled, the transmitter is terminated externally
- 1 = Enabled, the transmitter is terminated internally

**Bits 2 to 0: Transmit Resistor Adjustment (TRESADJ[2:0]).** These bits are used to adjust the internal termination resistance of the transmitter. See Section [9.2.8](#page-27-0).

 $000 = 75Q$  $001 = 82\Omega$  $010 = 90\Omega$  $011 = 100Ω$  $100 = 68\Omega$  $101 = 62\Omega$  $110 = 56\Omega$  $111 = 50\Omega$ 

<span id="page-69-0"></span>Register Name: **LIU.CR2**  Register Address: **n x 80h + 22h** 

**LIU Control Register 2** 

**Bit 5: Receive Fail 2 Enable (RFL2E).** This bit is used to enable the receive failure type 2 detection. See Section [9.3.8.](#page-31-0)

0 = Disable receive failure type 2 detection

1 = Enable receive failure type 2 detection

**Bit 4: Receive LIU Monitor Mode (RMON).** This bit is used to enable the receive LIU monitor mode preamplifier. Enabling the preamplifier adds about 14dB of linear amplification for use in monitor applications where the signal has been reduced 20dB using resistive attenuator circuits. **Note:** When enabled, the preamp is turned on or off automatically depending upon the input signal level. See Section [9.3.2.](#page-28-0)

 $0 =$  Disable the preamp

1 = Enable the preamp

**Bit 3: Receive Termination Resistor Enable (RTRE).** This bit indicates when the receiver internal termination is enabled. See Section [9.3.1](#page-28-0).

0 = Disabled, the receiver is terminated externally

1 = Enabled, the receiver is terminated internally

**Bit 2-0: Receive Resistor Adjustment (RRESADJ[2:0]).** These bits are used to adjust the internal termination resistance of the receiver. See Section [9.3.1.](#page-28-0)

 $000 = 75Q$  $001 = 82\Omega$  $010 = 90\Omega$  $011 = 100 Ω$  $100 = 68\Omega$  $101 = 62\Omega$  $110 = 56Ω$  $111 = 50\Omega$ 

<span id="page-70-0"></span>Register Name: **LIU.TWSCR1**  Register Address: **n x 80h + 24h** 

# **LIU Transmit Waveshaping Control Register 1**

See [Figure 9-1](#page-24-0), [Figure 9-2](#page-25-0), and [Figure 9-3](#page-26-0) for illustrations of the first and second rise/fall time segments of the DS3 and STS-1 waveforms and the overshoot, one level, undershoot, and zero level segments for the E3 waveform.

**Bits 15 and 14: Transmit Waveshaping Control (TWSC[15:14]).** In DS3 and STS-1 modes, this field adjusts the width of the first of two rising-edge segments. In E3 mode this field adjusts the width of the leading edge overshoot.

**E3 Behavior** 

- 01 increase first rise time by 0.1ns increase overshoot width
- 
- 

10 - decrease first rise time by 0.1ns decrease overshoot width 11 - decrease first rise time by 0.2ns decrease overshoot width

**Bits 13 and 12: Transmit Waveshaping Control (TWSC[13:12]).** In DS3 and STS-1 modes, this field adjusts the width of the second of two rising-edge segments. In E3 mode this field adjusts the width of the pulse plateau.

#### **DS3/STS-1 Behavior E3 Behavior**

00 - normal second rise time normal "one level" time

- 01 increase second rise time by 0.1ns increase "one level" time by 0.15ns<br>10 decrease second rise time by 0.1ns decrease "one level" time by 0.15ns 10 - decrease second rise time by  $0.1$ ns
- 11 decrease second rise time by 0.1ns decrease "one level" time by 0.3ns

**Bits 11 and 10: Transmit Waveshaping Control (TWSC[11:10]).** In DS3 and STS-1 modes, this field adjusts the width of the first of two falling-edge segments. In E3 mode this field adjusts the width of the trailing edge undershoot.

#### **DS3/STS-1 Behavior E3 Behavior**

- 01 increase first fall time by 0.1ns increase undershoot width by 0.15ns
- 
- 

10 - decrease first fall time by 0.1ns decrease undershoot width by 0.15ns 11 - decrease first fall time by 0.2ns decrease undershoot width by 0.3ns

**Bits 9 and 8: Transmit Waveshaping Control (TWSC[9:8]).** In DS3 and STS-1 modes, this field adjusts the width of the second of two falling-edge segments. In E3 mode this field adjusts the width of the zero after the trailing edge.

### **DS3/STS-1 Behavior** E3 Behavior

**Bits 7 and 6: Transmit Waveshaping Control (TWSC[7:6]).** In DS3 and STS-1 modes, this field adjusts the amplitude of the first of two rising-edge segments. In E3 mode this field adjusts the amplitude of the leading edge overshoot. The 11 value is a special case in which the entire pulse is made narrower.

### **DS3/STS-1 Behavior E3 Behavior**

- 01 decrease first rise amplitude 15%
- 11 decrease pulse width by  $0.15$ ns

00 - normal first rise amplitude<br>
01 - decrease first rise amplitude 15% decrease overshoot amplitude 2% 10 - increase first rise amplitude 15% increase overshoot amplitude 2%<br>11 - decrease pulse width by 0.15ns decrease pulse width by 0.15ns

<span id="page-71-0"></span>**Bits 5 and 4: Transmit Waveshaping Control (TWSC[5:4]).** In DS3 and STS-1 modes, this field adjusts the amplitude of the second of two rising-edge segments. In E3 mode this field has no effect, except for the 11 value, which is a special case in which the entire pulse is made wider.

### **DS3/STS-1 Behavior E3 Behavior**

- 00 normal rise amplitude normal pulse
- 01 decrease second rise amplitude 15% normal pulse

10 - increase second rise amplitude 15% normal pulse

11 - increase pulse width by 0.15ns increase pulse width by 0.15ns

**Bits 3 and 2: Transmit Waveshaping Control (TWSC[3:2]).** In DS3 and STS-1 modes, this field adjusts the amplitude of the first of two falling-edge segments. In E3 mode this field adjusts the amplitude of the trailing edge overshoot. The 11 value is a special case in which the entire pulse is made wider.

#### **DS3/STS-1 Behavior E3 Behavior**

- 00 normal first fall time 01 - decrease first fall amplitude 15% decrease undershoot 2%
- 
- 

10 - increase first fall amplitude 15% increase undershoot 2%

11 - increase pulse width by 0.15ns increase pulse width by 0.15ns

**Bits 1 and 0: Transmit Waveshaping Control (TWSC[1:0]).** In DS3 and STS-1 modes, this field adjusts the fall time of the second of two falling-edge segments. In E3 mode this field has no effect, except for the 11 value, which is a special case in which the entire pulse is made narrower.

### **DS3/STS-1 Behavior E3 Behavior**

- 00 normal second fall time normal pulse
- 01 decrease second fall amplitude 15% normal pulse
- 10 increase second fall amplitude 15% normal pulse
- 11 decrease pulse width by 0.15ns decrease pulse width by 0.15ns

**Bits 3 to 0: Transmit Waveshaping Control (TWSC[19:16]).** This field adjusts overall amplitude of the transmit output pulse.

0000 - nominal amplitude (see [Table 12-6](#page-98-0) and [Table 12-7\)](#page-98-0)

0001 - increase amplitude by 3.75%

0010 - increase amplitude by 7.5%

- 0011 increase amplitude by 11.25%
- 0100 increase amplitude by 15%
- 0101 increase amplitude by 20%
- 0110 increase amplitude by 25%
- 0111 increase amplitude by 30%
- 1000 decrease amplitude by 12.5%
- 1001 decrease amplitude by 9.375%
- 1010 decrease amplitude by 6.25%
- 1011 decrease amplitude by 3.125%

110X - increase amplitude to internal current limit

111X - increase amplitude to maximum, current limiting disabled
**Register Description:** Register Address: **n x 80h + 28h** 

<span id="page-72-0"></span>Register Name: **LIU.SR**<br>
Register Description: **LIU Status Register** 

**Bit 10: Transmit Driver Monitor (TDM).** This bit indicates when the transmit driver is faulty. See Section [9.2.9](#page-27-0).

 $0 =$  the transmit line driver is operating properly

 $1$  = the transmit line driver is faulty

**Bit 9: Transmit Output Failure (TFAIL).** This bit indicates when there is a failure on the transmit differential outputs (TXP/TXN). See Section [9.2.9](#page-27-0).

0 = an open or short has not been detected on TXP or TXN

1 = an open or short has been detected on TXP or TXN

**Bit 8: Loss of Master Clock (LOMC).** This bit indicates whether or not the appropriate reference clock (DS3, E3 or STS-1, depending on [PORT.CR2](#page-61-0):LM[1:0] setting) is available from the CLAD block. See Section [9.7.1.](#page-39-0)

 $0 =$  the master reference clock is present

1 = that master reference clock is not present

### **Bit 4: Receive Preamp Status (RPAS).** See Section [9.3.2](#page-28-0).

 $0 =$  the receiver preamp is off

1 = the receiver preamp is on

### **Bit 3: Receive Failure Type 1 (RFAIL1).** See Section [9.3.8.](#page-31-0)

0 = a receive failure type 1 has not been detected on RXP or RXN

1 = a receive failure type 1 has been detected on RXP or RXN

### **Bit 2: Receive Failure Type 2 (RFAIL2).** See Section [9.3.8.](#page-31-0)

0 = a receive failure type 2 has not been detected on RXP or RXN

1 = a receive failure type 2 has been detected on RXP or RXN

#### **Bit 1: Receive Loss of Lock (RLOL).** See Section [9.3.4](#page-29-0).

- $0 =$  the incoming clock frequency on RXP/RXN is within  $\pm$ 7700ppm of the master reference clock (MCLK)
- 1 = the incoming clock frequency on  $RXP/RXN$  is more than  $\pm$ 7900ppm away from the master reference clock (MCLK)

### **Bit 0: Analog Loss of Signal (ALOS).** See Section [9.3.5](#page-29-0).

0 = an analog LOS (ALOS) condition has not been detected

1 = an ALOS condition has been detected

<span id="page-73-0"></span>Register Name: **LIU.SRL**  Register Address: **n x 80h + 2Ah** 

Register Description: **LIU Status Register Latched** 

**Bit 12: Jitter Attenuator Full Latched (JAFL).** This bit is set when the jitter attenuator buffer is full, or when data has been lost due to a jitter attenuator buffer underflow or overflow. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):JAFIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE](#page-56-0):PnISRIE are all set. See Section [9.4](#page-34-0).

**Bit 11: Jitter Attenuator Empty Latched (JAEL).** This bit is set when the jitter attenuator buffer is empty, or when data has been lost due to a jitter attenuator buffer underflow or overflow. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE:](#page-74-0)JAEIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.4.](#page-34-0)

**Bit 10: Transmit Driver Monitor Change Latched (TDML).** This bit is set when the [LIU.SR:](#page-72-0)TDM bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):TDMIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 9: Transmit Output Failure Change Latched (TFAILL).** This bit is set when the [LIU.SR:](#page-72-0)TFAIL bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):TFAILIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 8: Loss of Master Clock Latched (LOMCL).** This bit is set when the [LIU.SR](#page-72-0):LOMC bit is set. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):LOMCIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 5: Receive Gain Level Change Latched (RGLCL).** This bit is set when the receive gain level ([LIU.RGLR](#page-75-0): RGL[7:0]) changes. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):RGLCIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 4: Receive Preamp Status Change Latched (RPASL).** This bit is set when the [LIU.SR](#page-72-0):RPAS bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):RPASIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 3: Receive Failure Type 1 Change Latched (RFAIL1L).** This bit is set when the [LIU.SR:](#page-72-0)RFAIL1 bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE:](#page-74-0)RFAIL1IE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 2: Receive Failure Type 2 Change Latched (RFAIL2L).** This bit is set when the [LIU.SR:](#page-72-0)RFAIL2 bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE:](#page-74-0)RFAIL2IE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 1: Receive Loss of Lock Change Latched (RLOLL).** This bit is set when the [LIU.SR:](#page-72-0)RLOL bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE:](#page-74-0)RLOLIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 0: Analog Loss of Signal Change Latched (ALOSL).** This bit is set when the [LIU.SR:](#page-72-0)ALOS bit changes state. When set, this bit causes an interrupt if interrupt enables [LIU.SRIE](#page-74-0):ALOSIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

<span id="page-74-0"></span>Register Name: **LIU.SRIE**  Register Address: **n x 80h + 2Ch** 

Register Description: **LIU Status Register Interrupt Enable** 

**Bit 12: Jitter Attenuator Full Interrupt Enable (JAFIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)JAFL bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt
- **Bit 11: Jitter Attenuator Empty Interrupt Enable (JAEIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)JAEL bit.
	- $0 =$  mask the interrupt
	- $1$  = enable the interrupt

### **Bit 10: Transmit Driver Monitor Interrupt Enable (TDMIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)TDML bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

### **Bit 9: Transmit Output Failure Interrupt Enable (TFAILIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)TFAILL bit.

- $0 =$  mask the interrupt
- 1 = enable the interrupt

### **Bit 8: Loss of Master Clock Interrupt Enable (LOMCIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)LOMCL bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

### **Bit 5: Receive Gain Level Change Interrupt Enable (RGLCIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)RGLCL bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

### **Bit 4: Receive Preamp Status Interrupt Enable (RPASIE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)RPASL bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

### **Bit 3: Receive Failure Type 1 Interrupt Enable (RFAIL1IE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)RFAIL1L bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

### **Bit 2: Receive Failure Type 2 Interrupt Enable (RFAIL2IE).** This bit is the interrupt enable for the [LIU.SRL:](#page-73-0)RFAIL2L bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt
- **Bit 1: Receive Loss of Lock Interrupt Enable (RLOLIE).** This bit is the interrupt enable for the [LIU.SRL](#page-73-0):RLOLL bit.
	- $0 =$  mask the interrupt
	- $1$  = enable the interrupt

### **Bit 0: Analog Loss of Signal Interrupt Enable (ALOSIE).** This bit is the interrupt enable for the [LIU.SRL](#page-73-0):ALOSL bit.

- $0 =$  mask the interrupt
- $1$  = enable the interrupt

<span id="page-75-0"></span>Register Name: **LIU.RGLR Register Address:** 

LIU Receive Gain Level Register<br>n x 80h + 2Eh

**Bits 7 to 0: Receive Gain Level (RGL[7:0]).** This field reports the real-time receiver gain level in 0.25dB increments. Values of 00–60h indicate receiver gain of 0dB to +24dB in 0.25dB increments. Values of F4–FFh indicate receiver gain of -3dB to -0.25dB in 0.25dB increments. See Section [9.3.3.](#page-29-0)

# **10.6 B3ZS/HDB3 Encoder Registers**

# **Table 10-6. B3ZS/HDB3 Encoder Register Map**

<span id="page-77-0"></span>Register Name: **LINE.TCR Register Address:** 

Register Description: **B3ZS/HDB3 Transmit Control Register** 

### **Bit 4: Transmit Zero Suppression Encoding Disable (TZSD)**

- 0 = zero suppression (B3ZS or HDB3) encoding is enabled
- 1 = zero suppression (B3ZS or HDB3) encoding is disabled, and only AMI encoding is performed

### **Bit 3: Excessive Zero Insert Enable (EXZI).** See Section [9.2.3.](#page-23-0)

- 0 = excessive zero event (EXZ) insertion is disabled
- 1 = excessive zero event insertion is enabled

### **Bit 2: BiPolar Violation Insert Enable (BPVI).** See Section [9.2.3.](#page-23-0)

- 0 = bipolar violation (BPV) insertion is disabled
- 1 = bipolar violation insertion is enabled.

**Bit 1: Transmit Single Error Insert (TSEI).** When [LINE.TCR](#page-77-0):MEIMS = 0, this bit is used to insert errors of the type(s) specified by EXZI and BPVI in the transmit data stream. A 0 to 1 transition causes a single error to be inserted. For a second error to be inserted, this bit must be set to 0, and then back to 1. **Note:** If [LINE.TCR:](#page-77-0)MEIMS is low, and this bit transitions more than once between error insertion opportunities, only one error is inserted. See Section [9.7.5](#page-42-0).

**Bit 0: Manual Error Insert Mode Select (MEIMS).** This bit specifies the source of the error insertion signal for the transmit encoder/decoder block. **Note:** If TMEI or TSEI is one, changing the state of this bit may cause an error to be inserted. See Section [9.7.5](#page-42-0).

- 0 = Block-level error insertion using the [LINE.TCR:](#page-77-0)TSEI control bit
- 1 = Port-level or global-level error insertion as specified by [PORT.CR1:](#page-60-0)MEIMS

# **10.7 B3ZS/HDB3 Decoder Registers**

# **Table 10-7. B3ZS/HDB3 Decoder Register Map**

<span id="page-79-0"></span>Register Name: **LINE.RCR**  Register Address: **n x 80h + 40h** 

Register Description: **B3ZS/HDB3 Receive Control Register** 

**Bit 3: E3 Code Violation Enable (E3CVE).** In E3 mode ([PORT.CR2:](#page-61-0)LM[1:0] = 01) this bit specifies whether the [LINE.RBPVCR](#page-82-0) register counts bipolar violations or E3 coding violations. **Note:** E3 line coding violations are defined in ITU O.161 as consecutive bipolar violations of the same polarity. This bit is ignored in B3ZS mode. See Section [9.3.6.2](#page-30-0).

- 0 = bipolar violations.
- 1 = E3 line coding violations

**Bit 2: Receive BPV Error Detection Zero Suppression Code Format (REZSF).** When REZSF = 0, BPV error detection detects a B3ZS signature if a zero is followed by a bipolar violation (BPV), and an HDB3 signature if two zeros are followed by a BPV. When REZSF = 1, BPV error detection detects a B3ZS signature if a zero is followed by a BPV that has the opposite polarity of the BPV in the previous B3ZS signature, and an HDB3 signature if two zeros are followed by a BPV that has the opposite polarity of the BPV in the previous HDB3 signature. **Note:** Immediately after a reset (RST or DPRST bit high), this bit is ignored. The first B3ZS signature is defined as a zero followed by a BPV, and the first HDB3 signature is defined as two zeros followed by a BPV. All subsequent B3ZS/HDB3 signatures are determined by the setting of this bit. *Note: The default setting (REZSF = 0) conforms to ITU O.162. The default setting may falsely ignore actual BPVs that are not codewords. It is recommended that REZSF be set to one for most applications. This setting is more robust to accurately detect codewords.* See Section [9.3.6.2.](#page-30-0)

**Bit 1: Receive Zero Suppression Decoding Zero Suppression Code Format (RDZSF).** When RDZSF = 0, zero suppression decoding detects a B3ZS signature if a zero is followed by a bipolar violation (BPV), and an HDB3 signature if two zeros are followed by a BPV. When RDZSF = 1, zero suppression decoding detects a B3ZS signature if a zero is followed by a BPV that has the opposite polarity of the BPV in the previous B3ZS signature, and an HDB3 signature if two zeros are followed by a BPV that has the opposite polarity of the BPV in the previous HDB3 signature. **Note:** Immediately after a reset (RST or DPRST bit high), this bit is ignored. The first B3ZS signature is defined as a zero followed by a BPV, and the first HDB3 signature is defined as two zeros followed by a BPV. All subsequent B3ZS/HDB3 signatures are determined by the setting of this bit. *Note: The default setting (RDZSF = 0) may falsely decode actual BPVs that are not codewords. It is recommended that RDZSF be set to one for most applications. This setting is more robust to accurately detect codewords.* See Section [9.3.6.2.](#page-30-0)

#### **Bit 0: Receive Zero Suppression Decoding Disable (RZSD)**

- 0 = zero suppression (B3ZS or HDB3) decoding is enabled
- 1 = zero suppression (B3ZS or HDB3) decoding is disabled, and only AMI decoding is performed

<span id="page-80-0"></span>Register Name: **LINE.RSR**<br>
Register Description: **B3ZS/HDE** Register Address: **n x 80h + 44h** 

**B3ZS/HDB3 Receive Status Register** 

### **Bit 3: Excessive Zero Count (EXZC).** See Section [9.3.6.](#page-30-0)

 $0 =$  the excessive zero count is zero

1 = the excessive zero count is one or more

### **Bit 1: Bipolar Violation Count (BPVC).** See Section [9.3.6](#page-30-0).

 $0 =$  the bipolar violation count is zero

 $1$  = the bipolar violation count is one or more

### **Bit 0: Loss of Signal (LOS).** See Section [9.3.5.](#page-29-0)

0 = the receive line interface is not in an LOS condition

1 = the receive line interface is in an LOS condition

**Bit 5: Zero Suppression Code Detect Latched (ZSCDL).** This bit is set when a B3ZS or HDB3 signature is detected. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE](#page-81-0):ZSCDIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.3.6](#page-30-0).

**Bit 4: Excessive Zero Latched (EXZL).** This bit is set when an excessive zero event is detected on the incoming bipolar data stream. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE](#page-81-0):EXZIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.3.6](#page-30-0).

**Bit 3: Excessive Zero Count Latched (EXZCL).** This bit is set when [LINE.RSR:](#page-80-0)EXZC transitions from zero to one. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE:](#page-81-0)EXZCIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.3.6](#page-30-0).

**Bit 2: Bipolar Violation Latched (BPVL).** This bit is set when a bipolar violation (or E3 LCV if enabled) is detected on the incoming bipolar data stream. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE:](#page-81-0)BPVIE. [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.3.6.](#page-30-0)

**Bit 1: Bipolar Violation Count Latched (BPVCL).** This bit is set when [LINE.RSR:](#page-80-0)BPVC transitions from zero to one. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE](#page-81-0):BPVCIE, [PORT.ISRIE](#page-64-0):LDSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set. See Section [9.3.6](#page-30-0).

**Bit 0: Loss of Signal Change Latched (LOSL).** This bit is set when [LINE.RSR](#page-80-0):LOS changes state. When set, this bit causes an interrupt if interrupt enables [LINE.RSRIE:](#page-81-0)LOSIE, [PORT.ISRIE:](#page-64-0)LDSRIE and [GLOBAL.ISRIE](#page-56-0):PnISRIE are all set. See Section [9.3.5](#page-29-0).

<span id="page-81-0"></span>Register Name: **LINE.RSRIE**  Register Address: **n x 80h + 48h** 

Register Description: **B3ZS/HDB3 Receive Status Register Interrupt Enable** 

**Bit 5: Zero Suppression Code Detect Interrupt Enable (ZSCDIE).** This bit is the interrupt enable for the [LINE.RSRL](#page-80-0):ZSCDL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 4: Excessive Zero Interrupt Enable (EXZIE).** This bit is the interrupt enable for the [LINE.RSRL](#page-80-0):EXZL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 3: Excessive Zero Count Interrupt Enable (EXZCIE).** This bit is the interrupt enable for the [LINE.RSRL:](#page-80-0)EXZCL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 2: Bipolar Violation Interrupt Enable (BPVIE).** This bit is the interrupt enable for the [LINE.RSRL:](#page-80-0)BPVL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 1: Bipolar Violation Count Interrupt Enable (BPVCIE).** This bit is the interrupt enable for the [LINE.RSRL](#page-80-0):BPVCL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Loss of Signal Interrupt Enable (LOSIE).** This bit is the interrupt enable for the [LINE.RSRL:](#page-80-0)LOSL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

<span id="page-82-0"></span>

**Bits 15 to 0: Bipolar Violation Count (BPV[15:0]).** These 16 bits indicate the number of bipolar violations detected on the incoming bipolar data stream. See Section [9.3.6.](#page-30-0)

**Bits 15 to 0: Excessive Zero Count (EXZ[15:0]).** These 16 bits indicate the number of excessive zero conditions detected on the incoming bipolar data stream. See Section [9.3.6.](#page-30-0)

# **10.8 BERT Registers**

## **Table 10-8. BERT Register Map**

<span id="page-84-0"></span>Register Name: **BERT.CR**  Register Address: **n x 80h + 50h** 

Register Description: **BERT Control Register** 

**Bit 7: Performance Monitoring Update Mode (PMUM).** This bit specifies the source of the performance monitoring update signal for the BERT block. See Section [9.7.4](#page-42-0). **Note:** If RPMU or LPMU is one, changing the state of this bit may cause a performance monitoring update to occur.

0 = Block-level update via [BERT.CR](#page-84-0):LPMU

1 = Port-level or global update as specified by [PORT.CR1:](#page-60-0)PMUM

**Bit 6: Local Performance Monitoring Update (LPMU).** When [BERT.CR:](#page-84-0)PMUM = 0, this bit updates the performance monitoring registers in the BERT block. When this bit transitions from low to high, the BERT.RBECR and BERT.RBCR registers are updated with the latest counter values and the counters are reset. This bit should remain high until the performance monitor update status bit [\(BERT.SR:](#page-88-0)PMS) goes high, and then it should be brought back low, which clears the PMS status bit. If a counter increment occurs at the exact same time as the counter reset, the counter is loaded with a value of one, and the "counter is non-zero" latched status bit is set. See Section [9.7.4](#page-42-0).

**Bit 5: Receive New Pattern Load (RNPL).** A zero to one transition of this bit causes the programmed test pattern (QRSS, PTS, PLF[4:0], PTF[4:0] in the [BERT.PCR](#page-85-0) register, and BSP[31:0] in the [BERT.SPR](#page-86-0) registers) to be loaded into the receive pattern generator. This bit must be changed to zero and back to one for another pattern to be loaded. Loading a new pattern forces the receive pattern generator out of the "Sync" state which causes a resynchronization to be initiated. **Note:** The test pattern fields mentioned above must not change for four RCLK cycles after this bit transitions from 0 to 1. See Section [9.5.1](#page-35-0).

**Bit 4: Receive Pattern Inversion Control (RPIC)**. See Section [9.5.1](#page-35-0).

- $0 =$  do not invert the incoming data stream
- $1 =$  invert the incoming data stream

**Bit 3: Manual Pattern Resynchronization (MPR).** A zero to one transition of this bit causes the receive pattern generator to resynchronize to the incoming pattern. This bit must be changed to zero and back to one for another resynchronization to be initiated. **Note:** A manual resynchronization forces the pattern detector out of the "Sync" state. See Section [9.5.2.](#page-36-0)

**Bit 2: Automatic Pattern Resynchronization Disable (APRD).** When APRD = 0, the receive pattern generator automatically resynchronizes to the incoming pattern if six or more times during the current 64-bit window the incoming data stream bit and the receive pattern generator output bit did not match. When APRD = 1, the receive pattern generator does not automatically resynchronize to the incoming pattern. **Note:** Automatic synchronization is prevented by not allowing the receive pattern generator to automatically exit the "Sync" state. See Section [9.5.2.](#page-36-0)

**Bit 1: Transmit New Pattern Load (TNPL).** A zero to one transition of this bit causes the programmed test pattern (QRSS, PTS, PLF[4:0], PTF[4:0] in the [BERT.PCR](#page-85-0) register, and BSP[31:0] in the [BERT.SPR](#page-86-0) registers) to be loaded into the transmit pattern generator. This bit must be changed to zero and back to one for another pattern to be loaded. **Note:** The test pattern fields mentioned above must not change for four TCLK cycles after this bit transitions from 0 to 1. See Section [9.5.1.](#page-35-0)

**Bit 0: Transmit Pattern Inversion Control (TPIC).** See Section [9.5.1](#page-35-0).

- $0 =$  do not invert the outgoing data stream
- $1$  = invert the outgoing data stream

Register Name: **BERT.PCR**  Register Address: **n x 80h + 52h** 

<span id="page-85-0"></span>Register Description: **BERT Pattern Configuration Register** 

**Bits 12 to 8: Pattern Tap Feedback (PTF[4:0]).** These five bits control the PRBS "tap" feedback of the pattern generator. The "tap" feedback is from bit y of the pattern generator  $(y = PTF[4:0] + 1)$ . These bits are ignored when the BERT block is programmed for a repetitive pattern (PTS = 1). For a PRBS signal, the feedback is an XOR of bit n and bit y. See Section [9.5.1](#page-35-0).

**Bit 6: QRSS Enable (QRSS).** See Section [9.5.1.](#page-35-0)

- 0 = Disabled: the pattern generator configuration is controlled by PTS, PLF[4:0], PTF[4:0], and BSP[31:0]
- 1 = Enabled: the pattern generator configuration is forced to a PRBS pattern with a generating polynomial of  $x^{20} + x^{17} + 1$ , and the output of the pattern generator is forced to one if the next 14 output bits are all zero.

**Bit 5: Pattern Type Select (PTS).** See Section [9.5.1.](#page-35-0)

- 0 = PRBS pattern
- 1 = repetitive pattern.

**Bits 4 to 0: Pattern Length Feedback (PLF[4:0]).** This field controls the "length" feedback of the pattern generator. The "length" feedback is from bit n of the pattern generator (n = PLF[4:0] +1). For a PRBS signal, the feedback is an XOR of bit n and bit y. For a repetitive pattern the feedback is bit n. See Section [9.5.1](#page-35-0).

### DS32501/DS32502/DS32503/DS32504 PRELIMINARY

<span id="page-86-0"></span>

**BERT Seed/Pattern (BSP[31:0]).** This 32-bit field is the programmable seed for a transmit PRBS pattern, or the programmable pattern for a transmit or receive repetitive pattern. BSP[31] is the first bit output on the transmit side for a 32-bit repetitive pattern or 32-bit PRBS. BSP[31] is the first bit input on the receive side for a 32-bit repetitive pattern. See Section [9.5.1.](#page-35-0)

<span id="page-87-0"></span>Register Name: **BERT.TEICR**  Register Description: **BERT Transmit Error Insertion Control Register**  Register Address: **n x 80h + 58h**  Bit # 15 14 13 12 11 10 9 8 Name | — | — | — | — | — | — | — | — Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 Bit # 7 6 5 4 3 2 1 0 Name — — TEIR[2:0] BEI TSEI MEIMS Default | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0

**Bits 5 to 3: Transmit Error Insertion Rate (TEIR[2:0]).** This field indicates the rate at which errors are automatically inserted in the output data stream. One out of every 10n bits is inverted, where n = TEIR[2:0]. A value of 0 disables error insertion. A value of 1 results in every 10th bit being inverted. A value of 2 result in every 100th bit being inverted. Error insertion starts when this field is written with a non-zero value. If this field is written during an error insertion, the new error rate is used after the next error is inserted. See Section [9.5.3.1](#page-38-0).

### **Bit 2: Bit Error Insertion Enable (BEI).** See Section [9.5.3.1.](#page-38-0)

- 0 = single-bit error insertion is disabled
- 1 = single-bit error insertion is enabled

**Bit 1: Transmit Single Error Insert (TSEI).** When [BERT.TEICR](#page-87-0):MEIMS = 0 and BEI = 1, this bit is used to insert singlebit errors in the outgoing BERT data stream. A 0 to 1 transition causes a single bit error to be inserted. For a second bit error to be inserted, this bit must be set to 0, and back to 1. **Note:** If MEIMS is low, and this bit transitions more than once between error insertion opportunities, only one error is inserted. See Section [9.7.5.](#page-42-0)

**Bit 0: Manual Error Insert Mode Select (MEIMS)**. This bit specifies the source of the error insertion signal for the BERT block. **Note:** If TMEI or TSEI is one, changing the state of this bit may cause a bit error to be inserted. See Section [9.7.5](#page-42-0).

- 0 = error insertion is initiated by the [BERT.TEICR:](#page-87-0)TSEI register bit
- 1 = error insertion is initiated by the transmit manual error insertion signal (TMEI) specified by the [PORT.CR1](#page-60-0):MEIMS register bit

<span id="page-88-0"></span>

**Bit 3: Performance Monitoring Update Status (PMS).** This bit is set when the performance monitoring registers ([BERT.RBCR](#page-91-0) and [BERT.RBECR\)](#page-90-0) have been updated. PMS is asynchronously forced low when the [BERT.CR](#page-84-0):LPMU bit ([BERT.CR](#page-84-0):PMUM = 0) or RPMU signal [\(BERT.CR:](#page-84-0)PMUM = 1) goes low. See Section [9.7.4](#page-42-0).

0 = The associated update request signal is low or not all register updates are completed

1 = The requested performance register updates are all completed

#### **Bit 1: Bit Error Count (BEC).** See Section [9.5.1.](#page-35-0)

- $0 =$  the bit error count is zero
- 1 = the bit error count is one or more

#### **Bit 0: Out Of Synchronization (OOS).** See Section [9.5.1](#page-35-0).

- 0 = the receive pattern generator is synchronized to the incoming pattern
- 1 = the receive pattern generator is not synchronized to the incoming pattern

**Bit 3: Performance Monitoring Update Status Latched (PMSL).** This bit is set when the [BERT.SR:](#page-88-0)PMS bit transitions from 0 to 1. When set, this bit causes an interrupt if interrupt enables [BERT.SRIE:](#page-89-0)PMSIE, [PORT.ISRIE:](#page-64-0)BSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 2: Bit Error Latched (BEL).** This bit is set when a bit error is detected in the received pattern. When set, this bit causes an interrupt if interrupt enables [BERT.SRIE:](#page-89-0)BEIE, [PORT.ISRIE](#page-64-0):BSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

**Bit 1: Bit Error Count Latched (BECL).** This bit is set when the [BERT.SR](#page-88-0):BEC bit transitions from 0 to 1. When set, this bit causes an interrupt if interrupt enables [BERT.SRIE:](#page-89-0)BECIE, [PORT.ISRIE:](#page-64-0)BSRIE and [GLOBAL.ISRIE](#page-56-0):PnISRIE are all set.

**Bit 0: Out Of Synchronization Latched (OOSL).** This bit is set when the [BERT.SR](#page-88-0):OOS bit changes state. When set, this bit causes an interrupt if interrupt enables [BERT.SRIE](#page-89-0):OOSIE, [PORT.ISRIE:](#page-64-0)BSRIE and [GLOBAL.ISRIE:](#page-56-0)PnISRIE are all set.

<span id="page-89-0"></span>Register Name: **BERT.SRIE**<br>
Register Description: **BERT Statu Register Address:** 

**BERT Status Register Interrupt Enable n x 80h + 60h** 

**Bit 3: Performance Monitoring Update Status Interrupt Enable (PMSIE).** This bit is the interrupt enable for the [BERT.SRL:](#page-88-0)PMSL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 2: Bit Error Interrupt Enable (BEIE).** This bit is the interrupt enable for the [BERT.SRL](#page-88-0):BEL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 1: Bit Error Count Interrupt Enable (BECIE).** This bit is the interrupt enable for the [BERT.SRL](#page-88-0):BECL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

**Bit 0: Out Of Synchronization Interrupt Enable (OOSIE).** This bit is the interrupt enable for the [BERT.SRL](#page-88-0):OOSL status bit.

 $0 =$  mask the interrupt

 $1$  = enable the interrupt

<span id="page-90-0"></span>

**Bit Error Count (BEC[23:0]).** This field is the holding register for an internal BERT bit error counter that tracks the number of bit errors detected in the incoming data stream since the last performance monitoring update. The internal counter stops incrementing when it reaches a count of FF FFFFh and does not increment when an OOS condition exists. This register is updated when a performance monitoring update is performed. See Section [9.7.4.](#page-42-0) The source for the performance monitoring update signal is specified by the [BERT.CR](#page-84-0):PMUM bit.

<span id="page-91-0"></span>

**Bit Count (BC[31:0]).** This field is the holding register for an internal BERT bit counter that tracks the total number of bit received in the incoming data stream since the last performance monitoring update. The internal counter stops incrementing when it reaches a count of FFFF FFFFh and does not increment when an OOS condition exists. This register is updated when a performance monitoring update is performed. See Section [9.7.4](#page-42-0). The source for the performance monitoring update signal is specified by the [BERT.CR](#page-84-0):PMUM bit.

## <span id="page-92-0"></span>**11. JTAG INFORMATION**

The DS3250x LIUs support the standard instruction codes SAMPLE/PRELOAD, BYPASS, and EXTEST. Optional public instructions included are HIGHZ, CLAMP, and IDCODE. The devices contain the following items, which meet the requirements set by the IEEE 1149.1 Standard Test Access Port and Boundary Scan Architecture:

Test Access Port (TAP) Bypass Register

TAP Controller **Boundary Scan Register** Instruction Register **Device Identification Register** 

The TAP has the necessary interface pins, namely [JTCLK](#page-21-0), [JTRST](#page-21-0), [JTDI,](#page-21-0) [JTDO,](#page-21-0) and [JTMS.](#page-21-0) Details on these pins can be found in [Table 8-9](#page-21-0). Details about the boundary scan architecture and the TAP can be found in IEEE 1149.1- 1990, IEEE 1149.1a-1993, and IEEE 1149.1b-1994.

IEEE 1149.1 requires a minimum of two test registers—the bypass register and the boundary scan register. The bypass register is a 1-bit shift register used with the BYPASS, CLAMP, and HIGHZ instructions to provide a short path between JTDI and JTDO. The boundary scan register contains a shift register path and a latched parallel output for control cells and digital I/O cells. DS3250x BSDL files are available at: [www.maxim-ic.com/TechSupport/telecom/bsdl.htm](http://www.maxim-ic.com/TechSupport/telecom/bsdl.htm).

An optional test register, the identification register, has also been included in the device design. The identification register contains a 32-bit shift register and a 32-bit latched parallel output. [Table 11-1](#page-92-0) shows the identification register contents for the DS32501, DS32502, DS32503, and DS32504 devices.

### **Table 11-1. JTAG ID Code**

# **12. ELECTRICAL CHARACTERISTICS**

# **ABSOLUTE MAXIMUM RATINGS**

*Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. These are stress ratings only, and*  functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not *implied. Exposure to the absolute maximum rating conditions for extended periods may affect device reliability.* 

*\*Ambient operating temperature range when device is mounted on a four-layer JEDEC test board with no airflow.* 

Note: The typical values listed in the following tables and operations at -40°C operation are not production tested, but are guaranteed by design.

## **Table 12-1. Recommended DC Operating Conditions**

### $(T_A = -40^{\circ}C \text{ to } +85^{\circ}C)$

## **Table 12-2. DC Characteristics**

### (VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.)

Note 1: TCLKn = CLKC = 51.84MHz; LMn[1:0] = 10 (STS-1 mode); TXPn/TXNn driving all ones into 75Ω resistive loads; analog loopback enabled; all other inputs at VDD33 or grounded; all other outputs open.

**Note 2:** Design targets. Actual values will be listed after device characterization.

**Note 3:** TCLKn = CLKC = 51.84MHz; other inputs at VDD33 or grounded; digital outputs left open circuited.

**Note 4: IFSEL ≠ 0, CLAD[6:0] = 0000000 (disabled), G1SRS[3:0] = 0000 (disable),**  $\overline{CS}$  **= 1 (inactive).** 

**Note 5:**  $0V < V_{IN} <$  VDD18 for all other digital inputs.

## **Table 12-3. Framer Interface Timing**

(VDD18 = 1.8V $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.) (See [Figure 12-1](#page-96-0) and [Figure 12-2](#page-96-0).)

**Note 1:** DS3 mode.

**Note 2:** 78MHz is the maximum instantaneous frequency for a gapped clock. The maximum average frequency is 45.094MHz for DS3, 34.643MHz for E3, and 52.255MHz for STS-1.

**Note 3:** E3 mode.

**Note 4:** STS-1 mode.

**Note 5:** Outputs loaded with 25pF, measured at 50% threshold.

**Note 6:** Not tested during production test.

Note 7: The LIU reference clock must be a ±20ppm low-jitter clock. See Section [9.7.1](#page-39-0) for more information on reference clocks.

**Note 8:** When TCLKI = 0, TPOS/TDAT and TNEG are sampled on the rising edge of TCLK. When TCLKI = 1, TPOS/TDAT and TNEG are sampled on the falling edge of TCLK.

**Note 9:** When RCLKI = 0, RPOS/RDAT and RNEG/RLCV are updated on the falling edge of RCLK. When RCLKI = 1, RPOS/RDAT and RNEG/RLCV are updated on the rising edge of RCLK.

**Note 10:** Outputs loaded with 25pF, measured between V<sub>OL(MAX)</sub> and V<sub>OH(MIN)</sub>.

**Note 11:** Measured between V<sub>IL(MAX)</sub> and V<sub>IH(MIN)</sub>.

<span id="page-96-0"></span>

**Figure 12-2. Receiver Framer Interface Timing Diagram** 

## **Table 12-4. Receiver Input Characteristics—DS3 and STS-1 Modes**

(VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.)

Note 1: An interfering signal (2<sup>15</sup> - 1 PRBS, B3ZS encoded, compliant waveshape, nominal bit rate) is added to the input signal. The combined signal is passed through 0 to 900 feet of coaxial cable and presented to the DS3250x receiver. This spec indicates the lowest signalto-noise ratio that results in a bit error ratio  $\leq 10^{-9}$ .

**Note 2:** Not tested during production test.

**Note 3:** Measured on the line side (i.e., the BNC connector side) of the 1:1 receive transformer (see [Figure 3-2](#page-7-0)). During measurement, incoming data traffic is unframed  $2^{15}$  - 1 PRBS.

**Note 4:** With respect to nominal 800mVpk signal.

### **Table 12-5. Receiver Input Characteristics—E3 Mode**

(VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.)

Note 1: An interfering signal (2<sup>23</sup> - 1 PRBS, B3ZS encoded, compliant waveshape, nominal bit rate) is added to the input signal. The combined signal is passed through 0 to 900 feet of coaxial cable and presented to the DS3250x receiver. This spec indicates the lowest signalto-noise ratio that results in a bit error ratio  $\leq 10^{-9}$ .

**Note 2:** Not tested during production test.

**Note 3:** Measured on the line side (i.e., the BNC connector side) of the 1:1 receive transformer (see [Figure 3-2](#page-7-0)). During measurement, incoming data traffic is unframed  $2^{23}$  - 1 PRBS.

**Note 4:** With respect to nominal 1000mVpk signal.

## **Table 12-6. Transmitter Output Characteristics—DS3 and STS-1 Modes**

(VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.)

**Note 1:** Measured on the line side (i.e., the BNC connector side) of the 1:1 transmit transformer [\(Figure 3-2\)](#page-7-0).

**Note 2:** Unframed all-ones output signal, 3kHz bandwidth.

**Note 3:** Measured with a jitter-free clock applied to TCLK and a bandpass jitter filter with 10Hz and 800kHz cutoff frequencies.

**Note 4:** With ±5% power supply.

## **Table 12-7. Transmitter Output Characteristics—E3 Mode**

(VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.)

**Note 1:** Measured on the line side (i.e., the BNC connector side) of the 1:1 transmit transformer [\(Figure 3-2\)](#page-7-0).

**Note 2:** Measured with a jitter-free clock applied to TCLK and a bandpass jitter filter with 10Hz and 800kHz cutoff frequencies.

**Note 3:** With ±5% power supply.

## **Table 12-8. Parallel CPU Interface Timing**

(VDD18 = 1.8V  $\pm$ 10%, VDD33 = 3.3V  $\pm$ 5%, AVDD = 1.8V  $\pm$ 5%, T<sub>A</sub> = -40°C to +85°C.) (See [Figure 12-3](#page-100-0), [Figure 12-4,](#page-100-0) [Figure 12-5](#page-101-0), [Figure 12-6](#page-101-0), [Figure 12-7,](#page-102-0) [Figure 12-8](#page-102-0), [Figure 12-9](#page-103-0), and [Figure 12-10](#page-103-0).)

**Note 1:** D[15:0] loaded with 50pF when tested as outputs.

Note 2: If a gapped clock is applied on TCLK and local loopback is enabled, read cycle time must be extended by the length of the largest TCLK gap.

**Note 3:** Not tested during production test.

**Note 4:** In nonmultiplexed bus applications [\(Figure 12-3](#page-100-0) to [Figure 12-6](#page-101-0)), ALE should be wired high. In multiplexed bus applications ([Figure 12-7](#page-102-0) to [Figure 12-10](#page-103-0)), A[9:1] should be wired to D[15:0] and the falling edge of ALE latches the address.

**Note 5:** t14 starts at the occurrence of the rising edge of ALE or A[9:1] valid whichever occurs later.

**Note 6:** In order to avoid bus contention, during a read cycle A[9:1] should be disabled prior to [RD](#page-19-0) or [DS](#page-19-0) being active.

#### **Table 15-1. Thermal Properties—Natural Convection**

**Note 1:** The package is mounted on a four-layer JEDEC standard test board with no airflow and dissipating maximum power.<br>**Note 2:** Theta-JA ( $\theta_{\text{in}}$ ) is the junction to ambient thermal resistance, when the package is m

**Note 2:** Theta**-**JA (θJA) is the junction to ambient thermal resistance, when the package is mounted on a four**-**layer JEDEC standard test board with no airflow and dissipating maximum power.

**Table 15-2. Theta-JA (**θ**JA) vs. Airflow** 

<b>FORCED AIR</b> (METERS PER <b>SECOND)</b>	THETA-JA $(\theta_{JA})$
	$22.4^{\circ}$ C/W
	$19.0^{\circ}$ C/W
	17.2°C/W
