Description

The CD74FCT543 three-state, octal register/transceiver uses a small geometry BiCMOS technology. The output stage is a combination of bipolar and CMOS transistors that limits the output HIGH level to two diode drops below V_{CC} . This resultant lowering of output swing (0V to 3.7V) reduces power bus ringing (a source of EMI) and minimizes V_{CC} bounce and ground bounce and their effects during simultaneous output switching. The output configuration also enhances switching speed and is capable of sinking 64 milliamperes.

This device contains two sets of eight D-Type latches with separate input and output controls for each set. For data flow from A to B, for example, the A to B Enable (\overline{CEAB}) input must be LOW in order to enter data from A0-A7 or to take data from B0-B7, as indicated in the Truth Table. With \overline{CEAB} LOW, a LOW signal on the A to B Latch Enable (\overline{LEAB}) input makes the A to B latches transparent; a subsequent LOW to HIGH transition of the \overline{LEAB} signal puts the A latches in the storage mode and their outputs no longer change with the A inputs. With \overline{CEAB} and \overline{OEAB} both LOW, the three state B output buffers are active and reflect the data present at the output of the A latches. Control of data from B to A is similar, but uses the \overline{CEBA} , \overline{LEBA} , and \overline{OEBA} inputs.
