

MP2183C

2.5V to 5.5V, 3A, Synchronous, Step-Down Converter with SS, PG, and Forced PWM in SOT583 Package

DESCRIPTION

The MP2183C is a monolithic, step-down, switch-mode converter with built-in internal power MOSFETs. It achieves 3A of continuous output current from a 2.5V to 5.5V input voltage range, with excellent load and line regulation. The output voltage can be regulated to as low as 0.6V.

A constant-on-time (COT) control scheme provides fast transient response and eases loop stabilization. Fault protections include cycle-by-cycle current limiting and thermal shutdown.

The MP2183C is ideal for a wide range of applications including high-performance DSPs, wireless power, portable and mobile devices, and other low-power systems.

The device requires a minimal number of readily available, standard external components. It is available in an ultra-small SOT583 package.

FEATURES

- Forced PWM Mode Operation
- 1.2MHz Switching Frequency
- EN for Power Sequencing
- 1% FB Accuracy
- Wide 2.5V to 5.5V Operating Input Range
- Output Adjustable from 0.6V
- Up to 3A Output Current
- 65mΩ and 35mΩ Internal Power MOSFET Switches
- 100% Duty On
- Output Discharge
- V_O OVP
- External Soft Start Control
- Short-Circuit Protection with Hiccup Mode
- Power Good
- Available in a SOT583 Package

APPLICATIONS

- Wireless/Networking Cards
- Portable Instruments
- Low-Voltage I/O System Power
- Multi-Function Printers

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

PACKAGE REFERENCE

PIN FUNCTIONS

Pin #	Name	Description
1	PG	Power good indicator. The output of this pin is an open drain.
2	VIN	Supply voltage. The MP2183C operates from a 2.5V to 5.5V unregulated input. A decoupling capacitor is required to prevent large voltage spikes from appearing at the input.
3	SW	Output switching node. SW is the drain of the internal, high-side, P-channel MOSFET. Connect the inductor to SW to complete the converter.
4	GND	Ground.
5	EN	On/off control.
6	SS	Soft start. Connect a capacitor across SS and GND to set the soft-start time to avoid start-up inrush current.
7	OUT	Output voltage power rail and input sense pin for output voltage. Connect the load to this pin. Use an output capacitor to decrease the output voltage ripple.
8	FB	Feedback pin. An external resistor divider from the output to GND, tapped to the FB pin, sets the output voltage.

ABSOLUTE MAXIMUM RATINGS ⁽¹⁾

Supply voltage (V_{IN})6.5V
 V_{SW}-0.3V (-5V for <10ns)
to 6.5V (8V for <10ns)
All other pins..... -0.3V to +6.5V

Charged-device model (CDM).....1250V

Recommended Operating Conditions ⁽³⁾

Supply voltage (V_{IN}) 2.5V to 5.5V
Operating junction temp (T_J) -40°C to +125°C

Thermal Resistance	θ_{JA}	θ_{JC}
SOT583		
EV2183C-TL-00A ⁽⁴⁾	58.....	13....°C/W
JESD51-7 ⁽⁵⁾	120.....	55....°C/W

Notes:

- Exceeding these ratings may damage the device.
- The maximum allowable power dissipation is a function of the maximum junction temperature T_J (MAX), the junction-to-ambient thermal resistance θ_{JA} , and the ambient temperature T_A . The maximum allowable continuous power dissipation at any ambient temperature is calculated by P_D (MAX) = $(T_J$ (MAX) - T_A) / θ_{JA} . Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- The device is not guaranteed to function outside of its operating conditions.
- Measured on EV2183C-TL-00A, 2-layer PCB.
- Measured on JESD51-7, 4-layer PCB. The value of θ_{JA} given in this table is only valid for comparison with other packages and cannot be used for design purposes. These values are calculated in accordance with JESD51-7, and simulated on a specified JEDEC board. They do not represent the performance obtained in an actual application.

ELECTRICAL CHARACTERISTICS

$V_{IN} = 3.6V$, $T_J = -40^{\circ}C$ to $+125^{\circ}C$ ⁽⁶⁾, typical value is tested at $T_J = 25^{\circ}C$. The over-temperature limit is guaranteed by characterization, unless otherwise noted.

Parameter	Symbol	Condition	Min	Typ	Max	Units
V_{IN} range			2.5		5.5	V
Under-voltage lockout rising threshold				2.3	2.45	V
Under-voltage lockout hysteresis threshold				350		mV
Supply current (shutdown)		$V_{EN} = 0V$, $T_J = 25^{\circ}C$		0	1	μA

FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram

OPERATION

The MP2183C uses constant-on-time control with input voltage feed forward to stabilize the switching frequency over the full input range. It achieves 2A of continuous output current from a 2.5V to 5.5V input voltage range, with excellent load and line regulation. The output voltage can be regulated to as low as 0.6V.

Constant-On-Time (COT) Control

Compared to fixed-frequency PWM control, COT control offers a simpler control loop and a faster transient response. By using input voltage feed forward, the MP2183C maintains a nearly constant switching frequency across the input and output voltage ranges. Estimate the switching pulse on time with Equation (1):

$$t_{ON} = \frac{V_{OUT}}{V_{IN}} \cdot 0.83\mu s \quad (1)$$

To prevent inductor current runaway during load transient, the MP2183C has a fixed minimum off time of 90ns.

Enable (EN)

When the input voltage exceeds the under-voltage lockout threshold (UVLO), typically 2V, the device is enabled by pulling the EN pin above 1.2V. Leave the EN pin floating or pull it down to ground to disable the MP2183C. There is an internal 2MΩ resistor from EN to ground.

When the device is disabled, the part goes into output discharge mode automatically, and its internal discharge MOSFET provides a resistive discharge path for the output capacitor.

Soft Start (SS)

The MP2183C has an external SS pin that ramps up the output voltage at a controlled slew rate to avoid overshoot during start-up. The SS pin charge current is about 3μA. The soft-start time is determined by the SS capacitor, and can be estimated with Equation (2):

$$T_{ss}(\text{ms}) = \frac{0.8 \cdot C_{ss}(\text{nF}) \cdot V_{REF}}{I_{ss}(\mu\text{A})} + 0.06 \cdot C_{ss}(\text{nF}) \quad (2)$$

Where t_{ss} is the soft-start time from 10% to 90% of V_{OUT} , C_{ss} is the SS capacitor, I_{ss} is the SS pin's charge current (typically 3μA), and V_{REF} is the reference voltage (typically 0.6V).

Current Limit

The MP2183C typically has a 5A high-side switch current limit. When the high-side switch reaches its current limit, the MP2183C remains in hiccup mode until the current drops. This prevents the inductor current from continuing to rise and damaging components.

Short Circuit and Recovery

The MP2183C enters short-circuit protection mode when it reaches the current limit, and tries to recover with hiccup mode. The MP2183C disables the output power stage, discharges the soft-start capacitor, then automatically retries soft start. If the short-circuit condition remains after soft start ends, the MP2183C repeats this cycle until the short circuit disappears and the output returns to its regulation level.

Over-Voltage Protection (V_O OVP)

The MP2183C monitors a resistor-divided feedback voltage to detect an over-voltage condition. When the feedback voltage (V_{FB}) exceeds 115% of the target voltage, the controller enters a dynamic regulation period (DRP). During this period, the LS-FET is on until the LS-FET current drops to -1.5A. The output discharges to maintain the normal range.

If the over-voltage condition still exists, the LS-FET turns on again after an 800ns time delay. The part exits this regulation period when V_{FB} drops below 105% of the reference voltage. If the dynamic regulation cannot limit V_{OUT} and the input detects the 6.1V input, OVP occurs. The MP2183C stops switching and does not operate until the input voltage drops below 6V.

Power Good Indicator

The MP2183 has an open-drain output and requires an external pull-up resistor (100kΩ to 500kΩ) for the power good indicator. When V_{FB} exceeds 90% of the regulation voltage, V_{PG} is pulled up to V_{OUT}/V_{IN} by the external resistor. If V_{FB} exceeds this window, the internal MOSFET pulls PG to ground. The MOSFET has a maximum $R_{DS(ON)}$ below 400Ω. When the VIN and EN pins are not available and PG has an external power supply pulled up, the PG self-bias voltage is below 0.7V.

APPLICATION INFORMATION

COMPONENT SELECTION

Setting the Output Voltage

The external resistor divider sets the output voltage (see the Functional Block Diagram on page 13). Select a feedback resistor (R1) that reduces the V_{OUT} leakage current, typically between 100kΩ and 200kΩ. There is no strict requirement on the feedback resistor. Ensure that R1 is greater than 10kΩ. Calculate R2 with Equation (3):

$$R2 = \frac{R1}{\frac{V_{OUT}}{0.6} - 1} \quad (3)$$

Figure 2 shows the feedback circuit.

Figure 2: Feedback Network

Table 1 lists the recommended resistor values for common output voltages.

Table 1: Resistor Values for Common Output Voltages

V _{OUT} (V)	R1 (kΩ)	R2 (kΩ)
1.0	200 (1%)	300 (1%)
1.2	200 (1%)	200 (1%)
1.8	200 (1%)	100 (1%)
2.5	200 (1%)	63.2 (1%)
3.3	200 (1%)	44.2 (1%)

Selecting the Inductor

Most applications work best with a 0.47μH to 4.7μH inductor. Select an inductor with a DC resistance below 25mΩ to optimize efficiency.

A high-frequency, switch-mode power supply with a magnetic device has strong electromagnetic interference (EMI). Any unshielded power inductors should be avoided. Metal alloy or multiplayer chip power inductors are ideal shielded inductors since they can

decrease the influence effectively. Table 2 lists the recommended inductor.

Table 2: Recommended Inductor List

Manufacturer P/N	Inductance (μH)	Manufacturer
74437324010	1.0	Würth
MPL-AL4020-1R0	1.0	MPS

For most designs, the inductance value can be calculated with Equation (4):

$$L_1 = \frac{V_{OUT} \times (V_{IN} - V_{OUT})}{V_{IN} \times \Delta I_L \times f_{OSC}} \quad (4)$$

Where ΔI_L is the inductor ripple current.

Choose an inductor current that is about 30% of the maximum load current. The maximum inductor peak current can be estimated with Equation (5):

$$I_{L(MAX)} = I_{LOAD} + \frac{\Delta I_L}{2} \quad (5)$$

Selecting the Input Capacitor

The step-down converter has a discontinuous input current, and requires a capacitor to supply the AC current to the converter while maintaining the DC input voltage. Use low-ESR capacitors for the best performance. Ceramic capacitors with X5R or X7R dielectrics are highly recommended because of their low ESR and small temperature coefficients. For most applications, a 22μF capacitor is sufficient. Higher output voltages may require a 44μF capacitor to improve system stability.

The input capacitor requires an adequate ripple current rating because it absorbs the input switching current. Estimate the RMS current in the input capacitor with Equation (6):

$$I_{C1} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)} \quad (6)$$

The worst-case occurs when V_{IN} = 2V_{OUT}, calculated with Equation (7):

$$I_{C1} = \frac{I_{LOAD}}{2} \quad (7)$$

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current.

The input capacitor can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality, ceramic 0.1µF capacitor as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide sufficient charge to prevent excessive voltage ripple at the input. The input voltage ripple caused by the capacitance can be estimated with Equation (8):

$$\Delta V_{IN} = \frac{I_{LOAD}}{f_{SW} \times C1} \times \frac{V_{OUT}}{V_{IN}} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)$$

(8)

Selecting the Output Capacitor

The output capacitor (C2) stabilizes the DC output voltage. Ceramic capacitors are recommended. Low-ESR capacitors are recommended to limit the output voltage ripple. The output voltage ripple can be calculated with Equation (9):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L_1} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times \left(R_{ESR} + \frac{1}{8 \times f_s \times C2}\right)$$

(9)

Where L_1 is the inductor value, and R_{ESR} is the equivalent series resistance (ESR) value of the output capacitor.

When using ceramic capacitors, the capacitance dominates the impedance at the switching frequency and causes most of the output voltage ripple. For simplification, the output voltage ripple can be estimated with Equation (10):

$$\Delta V_{OUT} = \frac{V_{OUT}}{8 \times f_{SW}^2 \times L_1 \times C2} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right)$$

(10)

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output ripple can be calculated with Equation (11):

$$\Delta V_{OUT} = \frac{V_{OUT}}{f_{SW} \times L_1} \times \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \times R_{ESR}$$

(11)

The characteristics of the output capacitor also affect the stability of the regulation system.

PCB Layout Guidelines

Proper layout of the switching power supplies is very important for proper function. Poor layout design can result in poor line or load regulation and stability issues. For the best results, refer to Figure 3 and follow the guidelines below:

1. Place the high-current paths (GND, IN, and SW) as close as possible to the device with short, direct, and wide traces.
2. Place the input capacitor as close as possible to the IN and GND pins.
3. Place GND's output capacitor as close as possible to the GND pins.
4. Place the external feedback resistors next to the FB pin.
5. Keep SW short and route it away from the feedback network.
6. Keep the V_{OUT} sense line as short as possible, and route it away from the power inductor and surrounding inductors.

Figure 3: Recommended PCB Layout

TYPICAL APPLICATION CIRCUIT

Figure 4: Typical Application Circuit for the MP2183C

Note: If $V_{IN} < 3.3V$, it is recommended to use more input capacitors.
