STEPPER MOTOR CONTROLLER

FEATURES:

- · Controls Bipolar and Unipolar Motors
- · Cost-effective, low current, pin compatible replacement for L297
- Torque ripple compensated half-steps LS8297CT
- · Half and full step modes
- Normal/wave drive
- Direction control
- Reset input
- Step control input
- Enable input
- PWM chopper circuit for current control
- Two over current sensor comparators with external references input
- All inputs and outputs TTL/CMOS compatible (TTL for 5V operation)
- Supply current < 400uA
- 4.75 to 7V Operation (VDD VSS).
- LS8297 (DIP), LS8297-S (SOIC), LS8297-TS (TSSOP)
- LS8297CT (DIP), LS8297CT-S (SOIC), LS8297CT-TS (TSSOP) – See Figure 1 –

DESCRIPTION:

The **LS8297** Stepper Motor Controller generates four phase drive signal outputs for controlling two phase Bipolar and four phase Unipolar motors. The outputs are used to drive two H-bridges for the two motor windings in the Bipolar motor or the four driver transistors for the two center- tapped windings in the Unipolar motor. The motor can be driven in full step mode either in normal drive (two-phase-on) or wave drive (one-phase-on) and half step mode. The **LS8297** provides two inhibit outputs which are used to control the driver stages of each of the motor phases. The circuit uses STEP, FRD/REV and HALF/FULL inputs in a translator to generate controls for the output stages.

A dual PWM chopper circuit using an on-chip oscillator, latches and voltage comparators are used to regulate the current in the motor windings. For each pair of phase driver outputs (PHA, PHB, and PHC, PHD) each pulse of the common internal oscillator sets the latch and enables the output. If the current in the motor winding causes the voltage across a sense resistor to exceed the reference voltage, VREF, at the comparator inputs, the latch is reset disabling the output until the next oscillator pulse.

The CONTROL input determines whether the chopper acts on the phase driver outputs or the inhibit outputs. When the phase lines are chopped, the non-active phase line of each pair (PHA, PHB or PHC, PHD) is activated rather than de-activating the active line to reduce dissipation in the load sensing resistors. Refer to Figure 5B for Bipolar motors. If PHA is high and PHB is low, current flows through Q1, motor winding, Q4 and sense resistor Rs. When chopping occurs, PHB is brought high and circulating current flows through Q1 and D3 and not through Rs resulting in less power dissipation in Rs. Current decay is slow using this method. When the Control input is brought low, chopping occurs by bringing INH1 low. In this case circulating current flows through D2, motor winding and D3 and through the power supply to ground causing the current to decay rapidly. For Unipolar motors, only inhibit chopping is used. Refer to Figure 6. When INH1 is brough low

April 2009

current in either half of the center tapped motor winding recirculates through the diode across it.

LS8297CT is the torque ripple compensated version of the **LS8297.** Torque imbalance resulting from alternating "one-phase on", "two-phase on" sequence of the half-step mode (see Figure 4) is eliminated in the **LS8297CT** by switching the sense reference voltage between 100% and 70.7% in alternate steps.

INPUT/OUTPUT DESCRIPTION:

OSC Input

An RC input with the resistor connected to VDD and the capacitor connected to ground determines the oscillator chopper rate. When connected as an oscillator, the oscillator output appears as a negative-going pulse at the Sync pin. If the Oscillator pin is tied to ground, the Sync pin becomes an input. Osc frequency, fosc = 1/0.69RC

SYNC

As an output the Sync can be used to drive Sync pins of other **LS8297**s. This eliminates the need for RC components for any other **LS8297** controllers used in the system. As an input the Sync can be driven by the **LS8297** that has the RC oscillator components or by any other system external clock.

PHA/PHB/PHC/PHD

Phase drive output signals for power stages. In a Bipolar motor PHA and PHB are used for one H-bridge while PHC and PHD are used for the other.

INH1/INH2 Outputs

These outputs are active low inhibit controls for motor drive outputs. INH1 controls driver stage using PHA and PHB signals while INH2 control driver stage using PHC and PHD signals. When the Control input is low, these outputs are chopped using the internal oscillator for current regulating.

CONTROL Input

When high, the phase <u>outputs</u>, <u>PHA</u>, <u>PHB</u>, <u>PHC</u> and <u>PHD</u> are chopped. When low, <u>INH1</u> and <u>INH2</u> are chopped. Normally, inhibit outputs are chopped. Phase chopping might be used with a Bipolar motor that does not store much energy to prevent fast current decay and a low useful torque.

ENABLE Input

When Enable input is low, INH1, INH2, PHA, PHB, PHC and PHD are brought low.

HOME Output

An open drain output that indicates when the **LS8297** is in its initial state with PHA, PHB, PHC, PHD = logic states 0101 respectively. Refer to Figure 4. In the active state the open drain device is off.

STEP Input

An active low pulse on this input causes the motor to advance one step. The step occurs on the rising edge of the step signal.

FRD/REV Input

A logic 1 on this input causes the motor to advance through the stepping sequence of Fig. 4. A logic 0 on this input cause the motor to reverse the sequence.

RESET Input

An active low on this input cause the motor to be restored to the home position (0101).

HALF/FULL Input

When high, half-step operation is selected. When low, fullstep operation is selected. One-phase on full step is selected by selecting full when stepping sequence is at an even state. Two-phase on full step operation is selected when stepping sequence is at an odd state. Refer to Figure 4.

SENSE1/ SENSE2 Inputs

Inputs for load current sense voltages from power stages using PHA and PHB drive signals or PHC and PHD drive signals, respectively.

VREF

Reference voltage for chopper circuit which determines the peak load current.

ABSOLUTE MAXIMUM RATINGS

Symbol	Parameter	Value	Unit
Vs	Supply Voltage	10	V
