

BGT60ATR24C

60 GHz radar sensor

Features

- 60 GHz radar sensor for FMCW operation
- 4 GHz bandwidth
- 2 TX / 4 RX channels
- Digital interface for chip configuration and radar data acquisition
- Optimized power modes for low-power operation
- Integrated state machine for independent operation

Potential applications

- Radar frontend for gesture sensing
- High resolution FMCW radars
- Short range sensing operations
- Hidden sensing applications behind radome

Product validation

Qualified for Automotive Applications.
Product Validation according to AEC-Q100/101

Description

BGT60ATR24C, an automotive 60 GHz radar sensor, enables ultra-wide bandwidth FMCW operation in a small package. Sensor configuration and data acquisition are enabled with a digital interface and the integrated state machine enables independent data acquisition with power mode optimization for lowest power consumption.

Introduction

1 Introduction

New smart sensors for gesture recognition can be based on radar systems, in special case, FMCW radars. Those systems can comprise several blocks: Radio Frequency (RF) front-end, Analog Base Band (ABB), Analog to Digital Converter (ADC), Phase Locked Loop (PLL), memory (FIFO e.g.) and Serial Peripheral Interface (SPI). Smart sensors require a high level of integration, thus, the components listed above should be integrated in a single chip solution. BGT60ATR24C offers this level of integration in a single chipset.

1.1 Product Overview

The core functionality of BGT60ATR24C is to transmit frequency modulated continuous wave (FMCW) signal via one of the two transmitter channels (TX) and receive the echo signals from the target object on the four receiving channels (RX). Each receiver path includes a baseband filtering, a VGA, as well as an ADC. The digitized output is stored in a FIFO. The data is transferred to an external host, microcontroller unit (MCU) or application processor (AP), to run radar signal processing. A typical implementation of a sensor system consists of two main blocks only (see Figure 1):

- BGT60ATR24C handles the RF signals and provides the sampled IF signals
- Application Processor which captures and processes the radar signals

Figure 1 Data flow in the complete radar sensor system

1.2 Potential Applications

The chipset has been designed to address mainly the following potential applications:

- Radar frontend for gesture sensing
- High resolution FMCW radars
- Short range sensing operations
- Hidden sensing applications behind radome

Introduction

1.3 BGT60ATR24C Bare Die Block Diagram

BGT60ATR24C block diagram is presented in Figure 2.

Figure 2 BGT60ATR24C Block diagram

Feature List:

- Integrated LDOs from 1.8 V to 1.5 V to supply the digital domain
- RF-Frontend at 60 GHz covering frequencies from 58.0 to 62.0 GHz with two TX and four RX channels
- Baseband chain consisting of high pass filter, low noise voltage gain amplifier (VGA), and antialiasing filters
- Four ADC channels with 12 bits resolution and up to 4 MSps sampling rate to sample the RX-IF channels
- Integrated RF-PLL, timers, counters, and FSM to run set of frames in standalone mode (no communication with AP required except first trigger and raw data transfer)
- Full duplex FIFO structure as data buffer (196 kbit = 8192 words x 24 bits)
- Linear Feedback Shift Register (LFSR) test pattern generator on chip for data transfer check
- 8 to 10 bits sensor ADC for power and temperature measurement
- Standard SPI mode for configuration and status register read accesses
- Dedicated power modes for power reduction
- An external 80 MHz reference oscillator is used as a system clock source
- BITE (Built in test equipment) for EOL test in production at Infineon to verify RF performance
- ChipID block provides info regarding the digital code version, the RF block version, and the RF configuration
- Fabricated with BiCMOS Infineon process technology
- Housed in an eWLB package

Introduction

1.4 BGT60ATR24C Pin Definition and Function

Figure 3 shows the pin definition the PG-VFWLB-76-1 eWLB package in top view. The function of each pin is described in Figure 3 and Figure 4 .

Introduction

1.4.1 IO and Supply Pins

Table 2 Input/Output Pins

Symbol	Type	Domain	Description	Domain
DIV_TEST	A _{OUT}	VDDRF	VCO divided by 16 output	Analog-RF
OSC_CLK	A _{IN}	VDDRF	80 MHz Xtal input (SYS_CLK) for PLL	Analog-RF
IRQ	D _{OUT}	VDDD	Interrupt output	Control FSM
SPI_CLK	D _{IN}	VDDD	SPI CLK input	SPI
CS_N	D _{IN}	VDDD	SPI chip select input, active low	SPI
DI	D _{IN} / D _{OUT}	VDDD	SPI signal from the host output (I/O pin for Quad-SPI)	SPI
DO	D _{IN} / D _{OUT}	VDDD	SPI signal to the host input (I/O pin for Quad-SPI)	SPI
DIO2	D _{IN} / D _{OUT}	VDDD	I/O pin for Quad-SPI	SPI
DIO3	D _{IN} / D _{OUT}	VDDD	HW reset pin (I/O pin for Quad-SPI)	SPI
TX1	A _{OUT}	VDDRF	Transmitter 1 output	Analog-RF
TX2	A _{OUT}	VDDRF	Transmitter 2 output	Analog-RF
RX1	A _{IN}	VDDRF	Receiver 1 input	Analog-RF
RX2	A _{IN}	VDDRF	Receiver 2 input	Analog-RF
RX3	A _{IN}	VDDRF	Receiver 3 input	Analog-RF
RX4	A _{IN}	VDDRF	Receiver 4 input	Analog-RF

Table 3 Supply Pins

Symbol	Type	Domain	Description	Domain
VDDD	V _{IN}	1.8 V	Digital supply voltage	Digital
VDDA	V _{IN}	1.8 V	Analog supply voltage	ADC
VAREF	V _{OUT}	1.2 V	Positive reference voltage output; for bypass cap	ADC
VDDVCO	V _{IN}	1.8 V	Analog supply voltage to the VCO	Analog-RF
VDDRF	V _{IN}	1.8 V	Analog supply voltage	Analog-RF
VDDLf	V _{IN}	3.3 V	Analog supply voltage for the level shifter of the PLL loop filter	Analog-RF
VDDPLL	V _{IN}	1.8 V	Analog supply voltage to the PLL	Analog-RF
VSSRF	GNDA	0 V	Analog ground connection	Analog-RF
VSSA	GNDA	0 V	Analog ground connection	ADC
VSSD	GNDD	0 V	Digital ground connection	Digital

Introduction

Abbreviations:

V_{IN} ... supply voltage input pin

D_{IN} ... digital input pin

D_{OUT} ... digital output pin

V_{OUT} ... supply voltage output pin

A_{OUT} ... analog output pin

A_{IN} ... analog input pin

GNDA ... analog ground connection

GNDD ... digital ground connection

1.5 BGT60ATR24C Functional Block Diagram

BGT60ATR24C consists of some main functional blocks:

- **RF Frontend** consisting of 4 Rx channels, 2 Tx channels, LO generation, and divider by 4/5, see chapter 7.1
- **ABB**, analog baseband consisting of high pass filter (HPF), VGA, anti-aliasing filter (AAF), see chapter 7.2
- **PLL**, 3rd order sigma-delta based to perform FMCW ramp
- **MADC**, 4 channel 12 bits differential SAR ADCs interfaced to the ABB via a driver and to the FIFO via a mux, see paragraph 8
- **SADC**, 8 to 10 bits single-ended SAR ADC used to sense the sensor data, see chapter 9
- **FIFO**, 196 kbit= 8192 words x 24 bits
- **Register banks**, 97 registers, see chapter 4
- **SPI**, up to 50 MHz clock
- **FSM**, finite state machine which manage the complete chip
- **Clock wise, two domains** can be identified:
 - 80 MHz system clock (SYS_CLK) domain for PLL, MADC, SADC, and FIFO
 - 50 MHz (e.g.) SPI clock
 - The main FSM syncs those two domains.

Introduction

Figure 5 **BGT60ATR24C functional overview**

2 General Product Specification

The reference for all specified data is the Infineon application board, available on request.

2.1 Absolute Maximum Ratings

Table 4 Absolute Maximum Ratings $T_b = -40^{\circ}\text{C}$ to 105°C , all voltages with respect to ground, positive current flowing into pin (unless otherwise specified). Parameters not subject to production test

Spec	Symbol	Unit	Value			Number	Condition
Parameter			Min	Typ	Max		
Supply Voltage	VDDD	V	-0.3		+2	2.1.1	
Supply Voltage	VDDA	V	-0.3		+2	2.1.2	
Supply Voltage	VDDRF	V	-0.3		+2	2.1.3	
Supply Voltage	VDDVCO	V	-0.3		+2	2.1.4	
Supply Voltage	VDDPLL	V	-0.3		+2	2.1.5	
Supply Voltage	VDDLf	V	-0.3		+3.7	2.1.6	
DC Voltage at all I/O Pins	$V_{I/O}$	V	-0.3		VDD+0.3	2.1.7	Not exceeding 2 V
RF Input Power Level	P_{RF}	dBm			+10	2.1.8	At the Rx input-port
Junction Temperature	T_j	$^{\circ}\text{C}$	-40		+145	2.1.9	
Storage Temperature	T_{stg}	$^{\circ}\text{C}$	-40		+150	2.1.10	

Warning: Stresses above the maximum values listed here may cause permanent damage to the device. Maximum ratings are absolute ratings; exceeding only one of these values may cause irreversible damage to the integrated circuit. Exposure to conditions at or below absolute maximum rating but above the specified maximum operation conditions may affect device reliability and lifetime. Functionality of the device might not be given under these conditions.

2.2 Range of Functionality

Table 5 Range of Functionality, VDDD= 1.71 to 1.89 V, $T_b = -40$ to $+105^{\circ}\text{C}$

Spec	Symbol	Unit	Value			Number	Condition
Parameter			Min	Typ	Max		
Supply Voltage	VDDD	V	1.71	1.8	1.89	2.2.1	Noise on each supply domain should not exceed the level of 20 μVpp in the frequency range 20 kHz- 700 kHz ¹⁾
Supply Voltage	VDDA	V	1.71	1.8	1.89	2.2.2	
Supply Voltage	VDDRF	V	1.71	1.8	1.89	2.2.3	
Supply Voltage	VDDVCO	V	1.71	1.8	1.89	2.2.4	
Supply Voltage	VDDPLL	V	1.71	1.8	1.89	2.2.5	
Supply Voltage	VDDLf	V	2.5	3.3	3.63	2.2.6	
Chip Backside Temperature	T_b	$^{\circ}\text{C}$	-40		105	2.2.7	Measured with the on-chip temperature sensor
Frequency Range	f_{RF}	GHz	58.0		62.0	2.2.8	
System Reference Frequency	f_{SYS_CLK}	MHz	75	80	85	2.2.9	1.8 V CMOS clock; 78 MHz not allowed

General Product Specification

Duty cycle of $f_{\text{SYS_CLK}}$	f_{DUTSYS}	%	45	50	55	2.2.10	
Rise and Fall Time of $f_{\text{SYS_CLK}}$	$t_{\text{RS,FS,SYS}}$	ns			6	2.2.11	
Phase Jitter of $f_{\text{SYS_CLK}}$	J_{PHSYS}	ps		1		2.2.12	BW: 12 kHz to 20 MHz

1) This value will ensure no artifact/false target in the Range-Doppler map when it is calculated with a minimum of 8 chirps.

2.3 Current Consumption

Table 6 Overall Current Consumption, VDD (all except LF) = 1.71 to 1.89 V and $T_b = -40$ to $+105^\circ\text{C}$

Spec	Symbol	Unit	Value			Number	Condition
Parameter			Min	Typ	Max

2.6 Product Validation

Qualified for Automotive Applications. Product Validation according to AEC-Q100/101.

3 Shapes, Frames, and Channel Set Definition

This chapter is intended to provide the user with an overview on the overall modulation and power modes capabilities of BGT60ATR24C. Specifically, the structure of timers, counters, shapes, channel set and frames will be presented. The chapter also gives a description of how the main FSM is setting and controlling the PLL for the expected modulation shapes and sequences programmed by the host.

3.1 Shapes and Frames

The shape is the modulation chirp that should be performed by the PLL. Two basic shapes are allowed (see Figure 6):

- triangular shape: consisting of a frequency Upchirp and a frequency Downchirp
- saw-tooth shape: consisting of a frequency Upchirp followed by a fast frequency Downchirp

The shapes are set and enabled in the PLLx[0..7] registers (see chapters 4.16 and 4.17) by the bit PLLx7_SH_EN. Up to four different shapes can be programmed. If more than one shape is used, the lower shapes must be programmed (e.g. 3 shapes are needed by the application than $x=1...3$).

N_SHAPE_EN is the number of shapes enabled.

Figure 6 Shape definition

Shape Group

Each shape defined above can be repeated several times (see Figure 7). The same shape repeated several times represents a shape group. The repetition factor for the shape is called REPSx and described in 4.17. Each shape is repeated up to $RSx=2^{REPSx}$ times.

Figure 7 Shape group

Shapes, Frames, and Channel Set Definition

After the last repetitions the FSM will enter, for a period $PLLx7:T_SED$ (see chapter 4.17), the power mode programmed according to what specified in $PLLx7:PD_MODE$ (see chapter 4.17).

After a shape group, the shape groups counter $STAT1: SHAPE_GRP_CNT$ is incremented (see chapter 4.5). In Figure 8, an example of four programmed shape groups is reported. It represents a shape set.

Figure 8 Shape set

Frame

A frame, as shown in Figure 9, is a sequence of shape sets followed by a specific power mode. Each shape set can be then repeated several times. The repetition factor for the shape set is called $REPTx$ and described in 4.12. Each shape is repeated up to $RTx = 2^{REPTx}$ times.

The length of a frame is defined through $CCR2: FRAME_LEN$ (see chapter 4.14), which is the number of shape groups to be executed.

At each start of a frame, the first shape $SHAPE1$ together with the first channel set, $CSU1+CSC1$ in 0, is loaded.

The number of frame groups the FSM will execute will be:

$$\min (FRAME_LEN, N_SHAPE_EN * RT)$$

With $RT \leq (4096/\text{shape groups})$ and 4095 maximum value allowed for $CCR2: FRAME_LEN$.

After the last shape group in a frame, the power mode from $CCR1: PD_MODE$ is used for the period programmed in $CCR1: T_FED$ instead of $PPLx7: MODE$ for period $PLLx7: T_SED$.

Figure 9 Example of one frame

Maximum Number of Frames

- The overall frame generation starts after the wake-up period with the first frame
- After the last frame $CCR2: MAX_FRAME_CNT$ (see chapter 4.14) is reached, the FSM will enter the Deep Sleep mode instead of the power mode defined at the end of the last frame
 - In order to trigger the chip again, an FSM reset is required.

Shapes, Frames, and Channel Set Definition

Figure 10 Maximum number of frames

3.2 Channel Set

Each channel set can be then repeated several times. The repetition factor for the channel set is called REPCx and described in 4.11. Each shape is repeated up to $RCx=2^{REPCx}$ times. There are in total 10 channel set registers and 6 channel set control registers of 3 different types acting in the specific “modes”. 8 channel sets relate to the shapes (4 shapes x “up” and “down” segment settings) and two to the power modes, Idle and Deep Sleep, respectively:

- Deep Sleep power mode is related to channel set CSDS and CSCDS
- Idle mode is related to channel set CSI and CSCI
- 8 channel sets are defined for the shapes:
 - CSU1 ... CSU4 registers for Upchirp
 - CSD1 ... CSD4 registers for Downchirp
 - CSC1 ... CSC4 channel set registers for up- and Downchirp
- Each shape from above has up to 2 channel sets CSUx and CSDx
 - In case triangular shape is used, CSUx and CSDx are applied
 - In case sawtooth shape is used, CSD is skipped
- Channel sets are repeating independent of the shapes
- Channel set repetition factor tells how often a single channel set is repeated until the next channel set is loaded
- On the channel set sequence:
 - The lower channel set number is followed by the next higher channel set number
 - In case the highest channel set number is reached, the next channel set loaded is channel set 1
- On the enabling sequence of channel sets:
 - In case not all channel sets are used, the lower number channel sets have to be used
 - In between the enabled channel sets must not be a disabled channel set
 - E.g. 2 channel sets expected: use only CS1 and CS2. In case 3 channel sets are expected, use only CS1, CS2, and CS3
- Start and end of channel set sequences:
 - After reset, the FSM is set to Deep Sleep and the first channel sets loaded are CSDS and CSCDS.
 - After a frame starts the first channel set loaded will be CS1

Note:

It would be preferable to have REPS=REPC. This is the actual implementation in the driver.

3.3 Power Modes

The following Figure 11 shows the flow chart on all possible power modes for the FSM.

Figure 11 FSM flow chart

Power Management through the Power Modes

The power modes enable the host to have full flexibility on power consumption during each state of radar frame generation. A set of isolation registers (CSCx see chapter 4.11) enables/disables the different blocks on chip. The power modes are managed by the FSM.

3.3.1 Mode Descriptions

In Active, Idle, and Deep Sleep mode the power mode can be defined in the CSCx register, see chapter 4.11, for all channel sets: CSC1..4, CSI, CSCDS (CSUx= Channel Set Upchirp, CSDx= Channel Set Downchirp, CSI= Channel Set Idle, CSDS= Channel Set Deep Sleep).

Active Mode Definition:

- During a shape: PLLx7: PD_MODE= 0_b
- Power mode defined through registers CSx (CS1..CS4), same mode for Up/Downchirp
- Default Setting: all expected settings are enabled by the host.

Interchirp Mode Definition:

- During a shape: PLLx7: PD_MODE= 0_b
- Power mode basically same as Active mode, exception: TX1 off (PA off).

Idle Mode Definition:

- After a shape: PLLx7: PD_MODE= 1_b
- After a frame: CCR1: PD_MODE= 1_b

Shapes, Frames, and Channel Set Definition

- Idle mode is defined through CSCI
- Wakeup from Deep Sleep for MAIN:TR_WKUP

The Idle mode can be used as a low-power mode in between Interchirp modes or after Deep Sleep mode to further reduce the overall power consumption while not entering the Deep Sleep mode. The wake-up times after Idle mode are faster compared to the ones after Deep Sleep mode.

Entering Deep Sleep Mode:

- After a shape: PLLx7: PD_MODE= 2_D and PLLx7: CONT_MODE= 0_B
- After a frame: CCR1: PD_MODE= 2_D and CCR0: CONT_MODE= 0_B
- Deep sleep mode is defined through CSCDS register (see chapter 4.11)
- All blocks can be turned off
- Internal 80 MHz clock is also turned off - to achieve extra power saving - when Cont Mode= 0_B otherwise (Cont Mode= 1_B) the clock is kept up to count the internal timer T_FED/T_SED during the deep sleep.
- In order to wake up the FSM from the Deep Sleep, the host has to program:
 - PACR1: OSCCLKEN= 1_B to enable the clock gating
 - Then the first trigger can be applied via FRAME_START.

Entering Deep Sleep Cont Mode:

- After a shape: PLLx7: PD_MODE= 2_D and PLLx7: CONT_MODE= 1_B
- After a frame: CCR1: PD_MODE= 2_D and CCR0: CONT_MODE= 1_B

In case CCR0: CONT_MODE= 1_B is enabled the wake-up from deep sleep is done automatically. The internal system clock is kept running.

In case of Errors:

If a FIFO overflow condition occurs, the FSM will bring the sensor into the Deep Sleep power mode even if the internal counters are holding the previous value, i.e., the FSM is not reset and a reset is required. In order to reset the FIFO, the host should send at least a MAIN: FIFO_RESET command (see chapter 4.2).

If the FIFO overflow occurs, the event is reported in FSTAT: FOF_ERR (see chapter 4.23) or in GSR0: FOF_ERR (see chapter 4.24).

In this case the data inside a FIFO can be read from the host as long as no reset occurs. “

The flags FSTAT: FOF_ERR and GSR0: FOF_ERR are cleared after a reset.

Note:

Each time the SPI will access the chip, the 80 MHz clock will be enabled internally for synchronization reasons.

3.3.2 Power Modes and Timings

This chapter presents the power modes and states that can be entered by the BGT60ATR24C FSM.

3.3.3 Wake-Up Phase from “Deep Sleep” to “Idle”

After VDDD power up the main LDO will require 20 μ s to settle VDDC. After the reset, the chip will change to a Deep Sleep state. The following figure describes the timing for waking up the chip.

Figure 12 Deep Sleep to Idle transition

Table 14 Transitions from Deep Sleep into Idle

From #	To #	Description	Signals	Related time
#0		Chip is reset by host (see chapter 5.10).		
#0	#1	Host programs all registers needed for expected functionality.		
#1		Host enables the oscillator: PACR1: OSCCLKEN= 1 _B to enable the clock gating.		
#1		Host starts the first trigger; it can be applied via FRAME_START.		
#1		Activate bandgap for MADC.		
#1	#2	Time required to settle the ADC BG (charge of external cap).		T_{WU}
#2		Enable PLL, MADC, and SADC.		
#2		MADC sends ready signal to FSM.	madc_rdy	

3.3.4 Idle to Interchirp then Active

Figure 13 Transition from Idle to Interchirp to Active to Interchirp again

Table 15 Transition from Idle to Interchirp to Active to Interchirp

From #	To #	Description	Signals	Related time
#1		Idle mode is activated.		
#1		Host has to enable the bandgap (CSCI:BG_EN= 1 _B in chapter 4.11).		
#1	#2	If Idle mode comes after a Deep Sleep (see transition from Deep Sleep to Idle).		T_WU
#1	#2	If Idle mode comes after an Interchirp mode, the bandgap is already running.		T_SED
#2		Interchirp Up mode is activated by selecting CSUx + CSCx register depending on the actual channel set (see chapter 3.3.5).		
#2		Host already enabled the blocks required by the PLL: CSx:VCO_EN = 1 _B CSx:FDIV_EN = 1 _B		
#2		FSM sets power mode from CSUx + CSCx.		
#2		FSM sets PACR1.RFILTSEL = 0 _B .		
#2	#3	The PLL needs some time to initialize the filter settings, 75 µs typ.		T_INIT0
#3	#4	The PLL needs again some time to settle the mode, 15 µs typ.		T_INIT1
#4		PLL sends lock signal to FSM.	PLL_lock	
#4		FSM give ramp_start signal to PLL.	RAMP_START	

Shapes, Frames, and Channel Set Definition

From #	To #	Description	Signals	Related time
#4	#5	PLL needs some settling time before chirp can start. The PLL timer is running in parallel to the FSM timer. T_START will be evaluated during system testing.		T_START (PLL)
#5	#9	PLL will run the frequency chirp.		T_RAMP (PLL)
#4	#6	Some programmable delay		T_PAEN
#6		Active mode starts here.		
#6		PA is enabled (PAON). Host makes sure that PA is not ON before the chirp starts (>#5).	PAON	
#6		Baseband reset timer is enabled here based on the CSx:BB_RSTCNT value.		
#6	#7	During this phase the baseband can settle.		T_SSTART
#7		MADC is triggered for the active segment (Up).	MADC_TRIG	
#7		SADC is triggered once here.		
#7	#8	MADC starts acquiring the given number of samples (PLLx:APU in chapter 4.16). See chapter 3.4.		T_ACQUx
#8		MADC has completed the acquisition of the expected number of samples.	MADC_DONE	
#8		PA is disabled (PAOFF) This condition must be reached before #9 The condition is: $T_{PAEN} + T_{SSTART} + T_{ACQUx} > T_{START} + T_{RAMPx}$.	PAOFF	
#8		Interchirp Up mode is activated again here (CSUx + CSCx).		
#9		PLL has completed the Upchirp.		
#9	#10	Programmable delay time (eg. 3 μ s).		T_END
#10		Ramp completed.	RAMP_DONE	
#10	#11	Programmable delay time (eg. 1 μ s).		T_EDU
#11		Interchirp Up mode ends here.		
#11		Interchirp Down mode is programmed here.		

3.3.5 Saw-tooth Shape Timing

In the saw-tooth mode, after a normal Upchirp segment there will be a fast ramp down segment. The saw-tooth shape should be enabled in the bitfield PACR2: FSTDNEN (see chapter 4.7). For the sawtooth only CSU (Upchirp) is used (see chapter 4.10). The time T_EDU (see chapter 4.16, PLLx2#) is applied after the segment is completed. See Figure 14.

Figure 14 Saw-tooth shape timing

3.3.6 Different Power Modes after Shapes and Shape Groups

After the shape ends with Downchirp, the chip can enter different power modes based on the settings (PLLx, CSx, CSCx, ...):

- Interchirp mode in-between shapes – for fast chirp repetitions
- Idle mode after shape groups – in case of longer delay between shape groups and max power saving is required
- Deep Sleep + Idle mode after shape groups in case if very long delays are expected.

3.3.6.1 Idle after Shape or Shape Groups

The Idle mode after a shape or shape groups can be set when a long time in low power mode between shapes is required. Figure 15 represents a time behavior continuation of what presented in Figure 13.

Figure 15 Idle mode after shape groups

Table 16 End of shape and interchirp in-between shapes

From #	To #	Description	Signals	Related time
#11		Interchirp Dn mode is programmed here (CSDx + CSCx).		
#11		FSM generates ramp_start signal.	Ramp_start	
		PLL related:		
#11	#12	Preparation for Downchirp.		T_START
#12	#16	Downchirp time.		T_RAMP
#16	#17	Some delay after Downchirp is completed.		T_END
		FSM related:		
#11	#13	Some delay (see above T_PAEN).		T_PAEN
#13		Active mode is entered with settings from previous Interchirp Dn mode (CSDx+CSCx).		
#13		PA is enabled (PAON). Host make sure that PA is not ON before the chirp starts (>#12).	PAON	
#13		Baseband reset timer is enabled here based on the CSx:BB_RSTCNT value.		
#13	#14	During this phase the baseband can settle		T_SSTAR
#14	#15	MADC starts acquiring the given number of samples (PLLx:APD in chapter 4.16). See chapter 3.4.	MADC_TRIG	T_ACQDx
#15		MADC has completed the acquisition of the expected number of samples.	MADC_DONE	
#15		PA is disabled (PAOFF)	PAOFF	

Shapes, Frames, and Channel Set Definition

From #	To #	Description	Signals	Related time
		This condition must be reached before #16 The condition is: $T_{PAEN} + T_{SSTART} + T_{ACQDx} > T_{START} + T_{RAMPx}$.		
#15		Interchirp Dn mode is activated again here ($CSDx + CSCx$).		
#14	#16	FSM waits for PLL if ramp down to calculate #17 (TMREND).		
#16		PLL signals the end of the Downchirp (ramp progress).	RampDN	
#17	#18	Time delay programmed by the host.		T_{EDD}
#18	#2	Time programed by the host to stay in Idle mode.		T_{SED}
#2		Same state #2 as in Figure 13 starts here.		

3.3.6.2 Interchirp in-between Shapes

Interchirp between shapes can be set when the required gap between two shapes is relatively small ($< 25 \mu s$).

Figure 16 Interchirp in-between shapes

Table 17 Interchirp in-between shapes

From #	To #	Description	Signals	Related time
#15		Interchirp Dn ($CSDx + CSCx$) is activated after Active mode.		
#16		PLL signals the end of the Downchirp (ramp progress).	RampDN	
#16	#17	Some delay after Downchirp is completed.		T_{END}
#17		PLL has completed its action.		
#17	#18	Time delay programmed by the host.		T_{EDD}
#18	#4	The chip will remain in the same interchirp power state for the provided amount of time (T_{EDD}).		T_{SED}
#4		Same state #4 as in Figure 13 starts here.		

Shapes, Frames, and Channel Set Definition

From #	To #	Description	Signals	Related time
#4		Interchirp Up mode programed by FSM here (CSUx + CSCx).		

3.3.6.3 Deep Sleep Continuous + Idle wake-up after shape groups

In Deep Sleep Cont(inuous) mode after the shape group is completed, the FSM wakes up automatically after the programed time T_{SED} . The internal clock is kept running during this time. Deep Sleep Cont is the only deep sleep power mode possible between shape groups.

Figure 17 Deep Sleep + Idle wake-up after shape groups

Shapes, Frames, and Channel Set Definition

Table 18 Deep Sleep Cont + Idle wake-up after shape groups

From #	To #	Description	Signals	Related time
#16	#17	Some delay after Downchirp is completed.		T_END
#17		PLL is completed its action.		
#17	#18	Time delay programmed by the host.		T_EDD
#17		Deep Sleep Cont mode is enabled. The difference to the normal Deep Sleep mode is, the $f_{\text{SYS_CLK}}$ is kept running to count the internal timers.		
#17		The internal system clock $f_{\text{SYS_CLK}}$ is kept running.		
#18	#1	The chip will be in Deep Sleep Cont mode.		T_SED
#1		Continuous trigger coming from the FSM.		
#1		Same start-up procedure as Figure 13 starts here.		

3.4 System Constraints

3.4.1 MADC Sampling Timing Conditions and Calculations

The number of MADC samples during a frequency chirp (up or down segment of the shape) shall fulfil some specific requirements.

Figure 18 T_RAMP timing conditions

Shapes, Frames, and Channel Set Definition

Table 19 T_RAMP Timing Conditions

From #	To #	Description	Signals	Related time
#4		PLL starts counting.		
#4	#5	PLL starts.		T_START
#5	#9	PLL performs the frequency Upchirp, chirp from fstart (PLLx[1]:FSU) to fstop.		T_RAMP
#6	#8	Active Phase.		
#4	#7	Time to start the MADC.		T_PAEN+T_SSTART
#7	#8	MADC sampling time for Upchirp raw data.		T_ACQUX
#8	#9	End chirp margin T_ECM is needed to avoid transmission out of band. Empirically derived in System.		T_ECM
#5	#7	Start chirp margin T_SCM is needed to avoid transmission out of band. Empirically derived in System.		T_SCM

ADC Sampling Rate $f_{\text{ADC_SAMP}}$ (see chapter 8.5.5):

$$f_{\text{ADC_SAMP}} = f_{\text{ADC_CLK}} / \text{ADC_DIV}$$

ADC acquisition time for Upchirp T_ACQUx:

$$T_{\text{ACQUx}} = \text{APUx} / f_{\text{ADC_SAMP}}$$

Where APU is the number of samples.

End chirp margin T_ECM is tested in system but assumed to be more than 0 μs :

$$T_{\text{ECM}} > 0\mu\text{s}, T_{\text{SCM}} > 0\mu\text{s}$$

Condition on the data acquisition start time:

$$T_{\text{PAEN}} + T_{\text{SSTART}} > T_{\text{START}}$$

Considering the start chirp margin TCM at the beginning:

$$T_{\text{PAEN}} + T_{\text{SSTART}} - T_{\text{SCM}} = T_{\text{START}}$$

Overall timing equation:

$$T_{\text{PAEN}} + T_{\text{SSTART}} + T_{\text{ACQUx}} + T_{\text{ECM}} = T_{\text{START}} + T_{\text{RAMP}}$$

Example, Fixed number of samples:

In case the user expects a fixed number of samples, the APU is set and T_RAMP is calculated.

The time for a frequency ramp T_RAMP is:

$$T_{\text{RAMP}} (\text{PLLx2\#}: \text{RTU in chapter 4.16}) = T_{\text{PAEN}} + T_{\text{SSTART}} + T_{\text{ACQUx}} + T_{\text{ECM}} - T_{\text{START}}$$

Example, Fixed chirp-time (T_RAMP):

$$T_{\text{ACQUx}} = T_{\text{RAMP}} - (T_{\text{SCM}} + T_{\text{ECM}})$$

$$\text{APU} = (T_{\text{ACQUx}} * f_{\text{ADC_SAMP}}),$$

$$\text{APU} (\text{PLLx3\#}: \text{APU in chapter 4.16}) = (T_{\text{RAMP}} - (T_{\text{SCM}} + T_{\text{ECM}})) * (f_{\text{SYS_CLK}} / \text{ADC_DIV})$$

3.4.2 PLL Frequency Ramp Setup

The RF frequency ramps generated by the PLL are controlled through the PLLx registers (see chapter 4.16), where the bit fields FSU, RSU and RTU control the Upchirp of a shape and the registers FSD, RSD and RTD control the down chirp of a shape. The following description refers only to up chirp ramp setup. The given formulas can be adopted to down chirp ramps by replacing FSU by FSD, RSU by RSD and RTU by RTD.

Each RF frequency ramp is defined by the start frequency programmed to FSU, the ramp slope programmed to RSU and the ramp time programmed to RTU. It must be noted that the slope in RSU is specified as frequency increment per clock cycle while the ramp time in RTU is specified as number of steps where a single step means 8 clock cycles. The relation between RSU and RTU is shown in Figure 19.

Figure 19 Relationship between RTU and RSU

The value N_{FSU} that is programmed to FSU bit field to control the ramp start frequency is a signed 2's complement number in the range of $[-2^{23} \dots (2^{23} - 1)]$. The relation between the RF frequency f_{RF} and N_{FSU} is given by:

$$f_{RF} = 8f_{SYSCLK} \left[4(N_{DIVSET} + 2) + 8 + \frac{N_{FSU}}{2^{20}} \right]$$

where f_{SYSCLK} is the frequency of the reference clock oscillator (typically 80 MHz) and N_{DIVSET} is the value programmed to the bit field DIVSET in register PACR2 (default 20, see chapter 4.7). Accordingly the value N_{FSU} can be calculated by this formula:

$$N_{FSU} = 2^{20} \left[\frac{f_{RF}}{8f_{SYSCLK}} - 4(N_{DIVSET} + 2) - 8 \right]$$

The value N_{RSU} that is programmed to RSU bit field to control the frequency increment per clock cycle is also a signed 2's complement number in the range of $[-2^{23} \dots (2^{23} - 1)]$. The relation between the RF frequency increment Δf_{RF} and N_{RSU} is given by:

$$\Delta f_{RF} = 8f_{SYSCLK} \frac{N_{RSU}}{2^{20}}$$

or

Shapes, Frames, and Channel Set Definition

$$N_{RSU} = 2^{20} \frac{\Delta f_{RF}}{8f_{SYSCLK}}.$$

Note:

Both slope bit fields *RSU* and *RSD* can hold positive and negative values, so an up chirp can also be programmed with a falling ramp and a down chirp can be programmed with a rising ramp. The naming convention “up chirp” and “down chirp” are based on the assumption that a triangle shape always starts with the rising ramp. Therefore, regardless of the actual ramp slope the up-chirp registers always refer to the first chirp of a shape and the down chirp registers always refer to the 2nd chirp of a shape in triangle mode.

PLL Setup Example 1 ($f_{SYSCLK} = 80\text{MHz}$)

With a reference clock frequency of 80 MHz the recommended value for N_{DIVSET} is 20, the default values. With these parameters the conversion formulas simplify to:

$$N_{FSU} = 2^{20} \left[\frac{f_{RF}}{640\text{ MHz}} - 96 \right]$$

and

$$N_{RSU} = 2^{20} \frac{\Delta f_{RF}}{640\text{ MHz}}$$

With the PLL's 24 bit 2's complement frequency registers the total programmable RF frequency range is $56.32\text{ GHz} \leq f_{RF} \leq 66.559\text{ GHz}$. This may be a wider range than the effectively achievable frequency range (see chapter 6 for PLL specification).

To achieve a frequency ramp from 58 GHz to 62 GHz in 36 μs , the FSU register is programmed to:

$$N_{FSU} = 2^{20} \left[\frac{58\text{ GHz}}{640\text{ MHz}} - 96 \right] = -5636096 \hat{=} AA0000_{hex}.$$

The ramp time bit field RTU is programmed to:

$$N_{RTU} = \frac{t_{ramp}}{8T_{SYSCLK}} = 36\text{ }\mu\text{s} \frac{80\text{ MHz}}{8} = 360.$$

The frequency increment per clock cycle result to:

$$\Delta f_{RF} = \frac{f_{RF,end} - f_{RF,start}}{8N_{RTU}} = \frac{62\text{ GHz} - 58\text{ GHz}}{8 \cdot 360} = \frac{4\text{ GHz}}{2880} = 1.389\text{ MHz}.$$

Accordingly the bit field RSU is programmed to:

$$N_{RSU} = 2^{20} \frac{1.389\text{ MHz}}{640\text{ MHz}} = 2275.8 \hat{=} 2276 \hat{=} 0008E4_{hex}$$

Due to rounding errors from the above calculation, the ramp will end at a slightly different end frequency:

$$f_{RF,end} = f_{RF,start} + 8 \cdot N_{RTU} \cdot \frac{640\text{ MHz}}{2^{20}} N_{RSU} = 62.000781\text{ GHz}.$$

Shapes, Frames, and Channel Set Definition

PLL Setup Example 2 ($f_{SYSCLK} = 76.8 \text{ MHz}$)

With a reference clock frequency of 76.8 MHz the recommended value for N_{DIVSET} is 21. With these parameters the conversion formulas simplify to:

$$N_{FSU} = 2^{20} \left[\frac{f_{RF}}{614.4 \text{ MHz}} - 100 \right]$$

and

$$N_{RSU} = 2^{20} \frac{\Delta f_{RF}}{614.4 \text{ MHz}}$$

With the PLL's 24 bit 2's complement frequency registers the total programmable RF frequency range is $56.5248 \text{ GHz} \leq f_{RF} \leq 66.3552 \text{ GHz}$. This may be a wider range than the effectively achievable frequency range (see chapter 6 for PLL specification).

To achieve a frequency ramp from 58 GHz to 62.0 GHz in 36 μs , the FSU register is programmed to:

$$N_{FSU} = 2^{20} \left[\frac{58 \text{ GHz}}{614.4 \text{ MHz}} - 100 \right] = -5870933.\bar{3} \cong -5870933 \cong A66AAB_{hex}.$$

The ramp time bit field RTU is programmed to:

$$N_{RTU} = \frac{t_{ramp}}{8T_{SYSCLK}} = 36 \mu\text{s} \frac{76.8 \text{ MHz}}{8} = 345.6 \cong 346.$$

The frequency increment per clock cycle result to:

$$\Delta f_{RF} = \frac{f_{RF,end} - f_{RF,start}}{8N_{RTU}} = \frac{62 \text{ GHz} - 58 \text{ GHz}}{8 \cdot 346} = \frac{4 \text{ GHz}}{2768} = 1.44509 \text{ MHz}.$$

Accordingly the bit field RSU is programmed to:

$$N_{RSU} = 2^{20} \frac{1.44509 \text{ MHz}}{614.4 \text{ MHz}} = 2466.28 \cong 2466 \cong 0009A2_{hex}.$$

Due to rounding errors from the above calculation, the ramp will end at a slightly different end frequency:

$$f_{RF,start} = 614.4 \text{ MHz} \left[100 + \frac{N_{FSU}}{2^{20}} \right] = 58.0000002 \text{ GHz}$$

$$f_{RF,end} = f_{RF,start} + 8 * N_{RTU} * \frac{614.4 \text{ MHz}}{2^{20}} N_{RSU} = 61.99954 \text{ GHz}.$$

4 BGT60ATR24C Registers

An array of registers visible via the SPI is used to control and program the states of the different blocks inside the chip.

4.1 Register List

The registers are arranged in blocks of 24 bits each. Each block is identified by its unique address. The registers are accessed from the SPI module. The bit fields from each register are arranged in MSB first order.

Table 20 The following table gives an overview on the BGT60ATR24C registers. Register Overview / Address Table

Register Address	Register Name	Description	RST	Section
0x00	MAIN	Main register		4.2
0x01	ADC0	MADC control register		4.3
0x02	CHIP_VERSION	Digital and RF version		4.4
0x03	STAT1	Status register 1		4.5
0x04	PACR1	PLL analog control register 1		4.6
0x05	PACR2	PLL analog control register 2		4.7
0x06	SFCTL	SPI and FIFO Control		4.8
0x07	SADC_CTRL	Sensor ADC ctrl reg		4.9
0x08	CSI_0	Channel set idle mode 0		4.10
0x09	CSI_1	Channel set idle mode 1		4.10
0x0A	CSI_2	Channel set idle mode 2		4.10
0x0B	CSCI	Channel set control idle mode		4.11
0x0C	CSDS_0	Channel set deep sleep mode 0		4.10
0x0D	CSDS_1	Channel set deep sleep mode 1		4.10
0x0E	CSDS_2	Channel set deep sleep mode 2		4.10
0x0F	CSCDS	Channel set control deep sleep mode		4.11
0x10	CSU1_0	Channel set 1 (up)		4.10
0x11	CSU1_1	Channel set 1 (up)		4.10
0x12	CSU1_2	Channel set 1 (up)		4.10
0x13	CSD1_0	Channel set 1 (down)		4.10
0x14	CSD1_1	Channel set 1 (down)		4.10
0x15	CSD1_2	Channel set 1 (down)		4.10
0x16	CSC1	Channel set control 1 (up/dn)		4.11
0x17	CSU2_0	Channel set 2 (up)		4.10
0x18	CSU2_1	Channel set 2 (up)		4.10
0x19	CSU2_2	Channel set 2 (up)		4.10
0x1A	CSD2_0	Channel set 2 (down)		4.10
0x1B	CSD2_1	Channel set 2 (down)		4.10
0x1C	CSD2_2	Channel set 2 (down)		4.10

BGT60ATR24C Registers

0x1D	CSC2	Channel set control 2 (up/dn)	4.11
0x1E	CSU3_0	Channel set 3 (up)	4.10
0x1F	CSU3_1	Channel set 3 (up)	4.10
0x20	CSU3_2	Channel set 3 (up)	4.10
0x21	CSD3_0	Channel set 3 (down)	4.10
0x22	CSD3_1	Channel set 3 (down)	4.10
0x23	CSD3_2	Channel set 3 (down)	4.10
0x24	CSC3	Channel set control 3 (up/dn)	4.11

0x60	CHIP ID #1	Chip ID #1 register		4.26
0x61	CHIP ID #2	Chip ID #2 register		4.27
>= 0x62		FIFO access		

Note: Reserved bits (RSVD) in the registers should not be modified. They should be kept in the default/reset state unless otherwise specified.

4.1.1 Abbreviations

Access modes on the registers:

- R ... Readable register or bit field
- W ... Writeable register or bit field
- W1C ... Writeable register or bit field, cleared by Hardware
- RSVD ... Reserved value which is not assigned at the moment

4.2 MAIN – Main Register

This register controls the top-level behavior of the chip.

Figure 20 MAIN register

Table 21 MAIN: Register Description

Symbol	Bits	Type	Description	RST
LDO_MODE	23	RW	The LDO settling time is defined by the LDO_MODE: 0 _B ... Low power (50 µA), slow settling time 1 _B ... High power (100 µA), fast settling time	0 _B
LOAD_STRENGTH	22:21	RW	Current spikes, overshoots and undershoots can occur on the VDDC during FSM transitions. Those can be smooth by applying a dummy load at the output of the LDO: 0 _D ... Disabled 1 _D ... 100 µA (current in the dummy load) 2 _D ... 200 µA (current in the dummy load) 3 _D ... 400 µA (current in the dummy load)	0 _D
MADC_BG_CLK_DIV	20:19	RW	MADC Bandgap clock divider Bandgap clock frequency divider value: 0 _D ... Bandgap clock off 1 _D ... Divider value is 1 2 _D ... Divider value is 2 3 _D ... Divider value is 4 Note: not “clock tree balanced”	3 _D
SADC_BG_CLK_DIV	18:17	RW	SADC Bandgap clock divider Bandgap clock frequency divider value: 0 _D ... SADC clock off 1 _D ... Divider value is 1 2 _D ... Divider value is 2 3 _D ... Divider value is 4 Note: not “clock tree balanced”	3 _D

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
CW_MODE	16	RW	Set to 1 _B : “Continuous Wave” mode: no shapes are executed but PLL / RF / ADC runs with values programmed in PDFT [0,1] registers and CS1.	0 _B
TR_WKUP_MUL	15:12	RW	Timer multiplier factor for wake-up time delay T_WU. Precise formula provided under MAIN:TR_WKUP	0 _D
TR_WKUP	11:4	RW	Coefficient to calculate T_WU: 0 _D ... T _{SYS_CLK} From 1 _D to 255 _D the time delay T_WU is calculated as follows: If TR_WKUP > 0, then the time delay is $T_{WU} = (TR_WKUP \times 2^{TR_WKUP_MUL \times 8 + TR_WKUP_MUL + 3}) \times T_{SYS_CLK}$ In typical use-case T_WUTYP = 1ms.	0 _D
FIFO_RESET	3	W1C	Clears and resets data_fifo: 0 _B ... No change 1 _B ... Reset the FIFO and return back to 0	0 _B
FSM_RESET	2	W1C	Control FSM reset: 0 _B ... No change 1 _B ... Reset the control FSM and return back to 0 _B	0 _B
SW_RESET	1	W1C	Software reset: 0 _B ... No change 1 _B ... Reset the register settings and return back to 0 _B	0 _B
FRAME_START	0	W1C	Starts frame generation. After the frame generation is started writing 1 _B : 0 _B ... No effect 1 _B ... Starts the frame generation It can be stopped by an FSM_RESET.	0 _B

4.3 ADC0 – MADC Control Register

The bits in this register are used to set properly the ADCs in the Rx chain.

Figure 21 ADC0 register

BGT60ATR24C Registers

Table 22 ADC0: Register Description

Symbol	Bits	Type	Description	RST
ADC_DIV	23:14	RW	Sampling frequency divider value. The actual sampling frequency will be $f_{\text{ADC_SAMP}} = f_{\text{ADC_CLK}} / \text{ADC_DIV}$: 20 _D ... minimum divider value → $f_{\text{ADC_SAMP}} = 4$ Msps 33 _D ... typical value → $f_{\text{ADC_SAMP}} = 2.42$ Msps 1023 _D ... max divider value → $f_{\text{ADC_SAMP}} = 78.201$ ksps	40 _D
RSVD	13	RW	RSVD	0 _B
TRIG_MADC	12	W1C	Test mode feature for single measurement acquisition. The results can be read through the test bits in registers ADC1 to ADC5: 0 _B ... Return value after trigger is captured internally 1 _B ... Single trigger event	0 _B
MSB_CTRL	11	RW	MSB decision time selection during calibration and conversion: 0 _B ... Single MSB decision time 1 _B ... Doubled MSB decision time	0 _B
TRACK_CFG	10:9	RW	Tracking conversion configuration bits: 0 _D ... No sub conversions are executed and averaged 1 _D ... 1 sub conversion 2 _D ... 3 sub conversions 3 _D ... 7 sub conversions	1 _D
DSCAL	8	RW	Disable Startup calibration: 0 _B ... startup calibration is enabled 1 _B ... startup calibration is disabled	0 _B
STC	7:6	RW	Sample time control: 0 _D ... 50 ns 1 _D ... 100 ns 2 _D ... 200 ns 3 _D ... 400 ns	1 _D
BG_CHOP_EN	5	RW	Enable chopping within the bandgap. 0 _B ... No chopping enabled 1 _B ... Chopping enabled	0 _B
BG_TC_TRIM	4:2	RW	Static temperature coefficient trimming 0 _D ... Min. value 7 _D ... Max. value	0 _D
ADC_OVERS_CFG	1:0	RW	Oversampling configuration: 0 _D Standard single 11 bits conversion Note: Oversampling must be set to 0 _D	0 _D

4.4 CHIP_VERSION

The register CHIP_VERSION provides information regarding the digital code version, the RF block version, and the RF configuration (number of TX/RX channels).

It is used by the driver to configure the device properly according to the info above.

Figure 22 **CHIP_ID register**

Table 23 **CHIP_ID: Register Description**

Symbol	Bits	Type	Description	RST
RSVD	23:16	R	Reserved	0 _D
DIGITAL_ID	15:8	R	5 _D ... BGT60ATR24C	5 _D
RF_ID	7:0	R	4 _D ... 2 Tx, 4 Rx	4 _D

4.5 **STAT1 - Status Register1**

The status register provides internal counter values for the actual number of frames and shapes. They are also provided to the data header. However, it should be mentioned that for all status registers, STAT0, STAT1, and FSTAT, with the exception of the FIFO status and error flags, updates to each status register field can happen on different timing events relative to FSM states and the field content should be treated independently from one-another. In CW mode the status bits can be read properly after e.g. 100 µs.

Figure 23 **STAT1: status register 1**

Table 24 **STAT1: Register Description**

Symbol	Bits	Type	Description	RST
FRAME_CNT	23:12	R	Frame counter value: 0 _D ... Reset value / after max. value rollover 4095 _D ... Max. value <i>Note: This field is for debug only. FRAME_CNT info should not be used when endless mode enabled (please check CCR2:MAX_FRAME_CNT)</i>	0 _D
SHAPE_GRP_CNT	11:0	R	Shape group counter counts the actual shape groups:	0 _D

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
			0 _D ... Reset value / after max. value for SHAPE_GRP_CNT reached 4095 _D ... Max. value	

Note:

1. A shape consists of an “Up Chirp” segment and a “Down Chirp” segment.
2. A sawtooth shape is generated by an “Up Chirp” and a “Fast Down Chirp”.
3. There is no data acquisition in the “Fast Down Chirp”.

4.6 PACR1: PLL Analog Control Registers 1

The bits in this register are used to properly set the PLL.

Figure 24 PACR1 register

Table 25 PACR1: Register Description

Symbol	Bits	Type	Description	RST
OSCCLKEN	23	RW	Enable clock path for system clock: 0 _B ... Clock off 1 _B ... Clock path active by default this is disabled This bit is controlled by FSM during operation. After deep sleep this bit should be enabled by the host. Before the MAIN: FRAME_START is raised the OSCCLKEN should be enabled!	0 _B
LFEN	22	RW	Enable loop filter: 0 _B ... Off(default) 1 _B ... On	0 _B
CPEN	21	RW	Enable charge pump: 0 _B ... Off(default) 1 _B ... On	0 _B
BIASFORC	20	RW	Use fixed biasing inside charge pump (= disable bias reg. loop): 0 _B ... Fixed biasing off = bias regulation loop active (default) 1 _B ... Fixed biasing on = bias regulation loop deactivated	1 _B

BGT60ATR24C Registers

ICPSEL	19:17	RW	Select charge pump current: 0 _D ... 40 µA 1 _D ... 80 µA 2 _D ... 120 µA 3 _D ... 160 µA 4 _D ... 200 µA (default) 5 _D ... 240 µA 6 _D to 7 _D ... 280 µA	4 _D
LOCKFORC	16	RW	Force lock signal to high: 0 _B ... Lock signal not forced 1 _B ... Lock forced to high	1 _B
LOCKSEL	15:13	RW	Select lock detection range/window: 0 _B ... 265 ps 4 _B ... 2 ns 1 _B ... 500 ps 5 _B ... 2.8 ns 2 _B ... 1 ns 6 _B ... 3.8 ns 3 _B ... 1.5 ns (default) 7 _B ... 4.6 ns	3 _D
RSVD	12	RW	Reserved Read as 0 _B , must be written with 0 _B .	0 _B
RLFSEL	11	RW	Select Rlf inside the loop filter: 0 _B ... Rlf= 5 kOhm (default) 1 _B ... Rlf= 7 kOhm	0 _B
RFILTSEL	10	RW	Select Rfilt of the reference filter: 0 _B ... Rfilt= 100 kOhm 1 _B ... Rfilt= 1 MOhm (default) Switch together with CPEN from 0 _d to 1 _d to improve start-up time!	1 _B
VREFSEL	9:8	RW	Select reference voltage/common mode level of loop filter: 0 _D ... 433 mV 1 _D ... 506 mV (default) 2 _D ... 578 mV 3 _D ... 650 mV	1 _D
U2IEN	7	RW	Enable voltage-to-current-converter: 0 _B ... off (default) 1 _B ... on	0 _B
BGAPEN	6	RW	Enable bandgap reference: 0 _B ... off (default) 1 _B ... on	0 _B
VDIGREG	5:4	RW	Program output voltage of dig-regulator: 0 _D ... 1.44 V 1 _D ... 1.5 V 2 _D ... 1.55 V (default) 3 _D ... 1.60 V (@Vbg=1.2 V)	2 _D
DIGPON	3	RW	Enable dig-regulator: 0 _B ... Power off (default) 1 _B ... Power on	0 _B

BGT60ATR24C Registers

VANAREG	2:1	RW	Program output voltage of ana-regulator: 0 _D ... 1.44 V 1 _D ... 1.5 V 2 _D ... 1.55 V (default) 3 _D ... 1.60 V (@V _{bg} =1.2 V)	2 _D
ANAPON	0	RW	Enable analog-regulator: 0 _B ... Power off (default) 1 _B ... Power on	0 _B

4.7 PACR2: PLL Analog Control Registers 2

The bits in this register are used to properly set the PLL.

Figure 25 PACR2 PLL register

Table 26 PACR2: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:20	RW	Reserved	0 _D
DTSEL	19:18	RW	Set PFD dead time / dead zone: 0 _D ... 180 ps to 350 ps 1 _D ... 270 ps to 510 ps (default) 2 _D ... 360 ps to 680 ps 3 _D ... 450 ps to 840 ps	1 _D
TRIVREG	17	RW	Set regulator off-state to tristate (for both ana- & dig-regulator): 0 _B ... Off state is 0.0 V (default) 1 _B ... Off state is to tristate (setting active for dig-regulator if DIGPON = 0 _B ; setting active for ana-regulator if ANAPON = 0 _B)	0 _B
FSDNTMR	16:8	RW	Defines the time for the PLL loop filter discharge during fast down chirp operation. When FSDNTMR = 0 _D and FSTDNEN is ≠ 0 _D , the fast down chirp length is internally assigned to a default value (@typ f _{SYS_CLK}): 0 _D ... 500 ns if FSTDNEN = 1 _D (discharge of the loop filter to the reference voltage set to PACR2:VREFSEL)	0 _D

BGT60ATR24C Registers

			0_D ... 700 ns if FSTDNEN = 2_D (discharge of the loop filter in a defined time window) 0_D ... 300 ns if FSTDNEN = 3_D For FSDNTMR > 0_D the discharge time will be $T_{SYS_CLK} \times (FSDNTMR+1)$: 1_D ... 25 ns 2_D ... 37.5 ns ... 511_D ... 6.4 μs Suggested settings for the discharge time: PACR2: FSDNTMR= 5_D Together with: PACR2: FSTDNEN= 2_D Depending on the specific modulation bandwidth set, specific settings can be defined.	
FSTDNEN	7:6	W	FAST DOWN CHIRP enable (see Note below): 00_B ... Disable (default) 01_B ... Enable fast down chirp (mode 1) 10_B ... Enable fast down chirp (mode 2) 11_B ... Enable fast down chirp (mode 3) Suggested settings for the fast-down mode (active mode between chirps): PACR2: FSDNTMR= 5_D Together with: PACR2: FSTDNEN= 2_D Depending on the specific modulation bandwidth set, specific settings can be defined.	00 _B
DIVEN	5	RW	Enable divider: 0_B ... Off: Input clock of divider and 80 MHz clock gated 1_B ... On: clocks released	0 _B
DIVSET	4:0	RW	Set fixed part of integer division factor (consider offset of 2). Default = 20_D, valid for a 80 MHz system clock. 21_D should be used for a 76.8 MHz system clock.	20 _D

Note:

This bit field is typically used by the FSM. In case not used, the FSM switches the bit field back to the default value.

4.8 SFCTL – SPI and FIFO Control Register

This register is used to configure the SPI and FIFO.

Figure 26 SPI and FIFO Control Register

Table 27 SPI and FIFO Control: Register Description

Symbol	Bits	Type	Description	RST
QSPI_WT	23:20	RW	Number of QSPI wait cycles (see QSPI section): 0 _D ... 1 cycle delay 15 _D ... 16 cycles delay	7 _D
RSVD	19	RW	RSVD	0 _B
PREFIX_EN	18	RW	Enables the data header written into the FIFO prior to the sampling data of each chirp: 0 _B ... No prefix data header prior to chirp data 1 _B ... Prefix data header added prior to chirp data (see chapter 5.1 for data header)	0 _B
LFSR_EN	17	RW	Enable LFSR register data generation: 0 _B ... Normal data acquisition, LFSR reset 1 _B ... LFSR data generation started LFSR should be enabled after a FIFO reset to ensure an empty FIFO (see also chapter 5.11).	0 _B
MISO_HS_RD	16	RW	0 _B ... MISO data is sent with falling edge of SPI CLK 1 _B ... MISO data is sent with rising edge (½ cycle earlier) Note: HS_RD = 0 _B can only be used for a SPI clock < 25 MHz. For HS-transfer please check the timing of the SPI Master and adjust settings accordingly. The setting becomes active when the last bit of FSCTL is clocked out and it affects MISO immediately. See also chapter 5.3.1.	1 _B
RSVD	15:14	RW	RSVD	0 _B
FIFO_LP_MODE	13	RW	FIFO power mode: 0 _B ... FIFO permanently enabled 1 _B ... FIFO activated dynamically	0 _B
FIFO_CREF	12:0	RW	FIFO compare reference: it defines the compare filling status for interrupt and CREF reporting When filling status is > FIFO_CREF an interrupt is issued:	0 _D

Symbol	Bits	Type	Description	RST
			0_D ... minimum value is 0, interrupt generated in case first sample is written into FIFO 8191_D ... maximum value in case FIFO is full with 8192 memory locations e.g. CREF = $0x1000$ represents a 50% compare reference	

4.9 SADC_CTRL Sensor ADC Control Register

The bits in this register are used to properly set the sensor ADC (SADC) used to monitor the on chip sensor outputs, temperature and power, as well as some internal voltage nodes.

Figure 27 SADC_CTRL registers

Table 28 SADC_CTRL: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:17	RW	RSVD	0_D
TC_TRIM	16:14	RW	Bandgap trim value: 0_D ... Min. trim value 7_D ... Max. trim value	0_D
DSCAL	13	RW	Disable startup calibration: 0_B ... Startup calibration enabled 1_B ... startup calibration disabled	0_B
LVGAIN	12	RW	Sample configuration for LV channels: 0_B ... Gain = 1.0 1_B ... Gain = 0.75	0_B
SESP	11	RW	Spreaded early sampling point enable: 0_B ... Disabled 1_B ... Enabled	0_B
OVERS_CFG	10:9	RW	Oversampling configuration: 0_D ... No oversampling → 8 bits resolution 1_D ... Oversampling by 2 2_D ... Oversampling by 4 → 9 bits resolution 3_D ... Oversampling by 32 → 10 bits resolution	0_D
SD_EN	8	RW	Sigma delta loop enable: 0_B ... Disabled	0_B

Table 28 SADC_CTRL: Register Description

Symbol	Bits	Type	Description	RST
			1 _B ... Enabled	
SADC_CLK_DIV	7:6	RW	SADC clock divider sets the clock for the sensing ADC. The divider value is defined as: 0 _D ... divider value is 1 (80 MHz e.g.) 1 _D ... divider value is 2 (40 MHz e.g.) 2 _D ... divider value is 3 (26 MHz e.g.) 3 _D ... divider value is 4 (20 MHz e.g.)	3 _D
RSVD	5	RW	RSVD	0 _D
SADC_START	4	WC1	SADC trigger: 1 _B ... Trigger the SADC to start a measurement 0 _B ... Default value or value after the trigger is captured; internally the value is set back to SADC_START= 0 _B .	0 _B
SADC_CHSEL	3:0	RW	Analog multiplexer input for channel selection into the SADC: 0 _D ... Temperature Sensor 1 _D ... RSVD 2 _D ... Temperature Sensor reference 3 _D ... ifx_mix4 4 _D ... if_mix4 5 _D ... ifx_mix3 6 _D ... if_mix3 7 _D ... ifx_mix2 8 _D ... if_mix2 9 _D ... ifx_mix1 10 _D ... if_mix1 11 _D ... pd1_outx 12 _D ... pd1_out 13 _D ... pd2_outx 14 _D ... pd2_out 15 _D ... RSVD	0 _D

4.10 CSx: Channel Set Registers

The channel set registers together with the channel set control registers defines the RF and baseband behavior during the shapes. CSUx= Channel Set Upchirp, CSDx= Channel Set Downchirp, CSI= Channel Set Idle, CSDS= Channel Set Deep Sleep.

4.11 CSCx - Channel Set Control Register

The channel set control register CSCx is related to the channel set register CSUx and CSDx as well as to CSI and CSDS, see description in chapter 4.10.

Besides REPC, all other bits are used to define a specific power mode.

“_ISOPD” represent a logical isolation layer and are used to disable one main block (MADC e.g.) preserving its configuration (no change in the ADC0 register configuration e.g.).

REPC is one parameter used to define the modulation sequence, see also 3.2.

Figure 29 Channel Set Control Register

Table 32 CSCx: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:12	RW	RSVD	0_D
PLL_ISOPD	11	RW	Isolation pin to disable the PLL: $0_B \dots$ PLL is connected $1_B \dots$ PLL is isolated	1_B
BG_TMRF_EN	10	RW	Required for temperature sensor readout: $0_B \dots$ Disabled	0_B

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
			1 _B ... Enabled	
SADC_ISOPD	9	RW	Enable the isolation of all control signals towards the sensor ADC: 0 _B ... SADC connected 1 _B ... SADC isolated	1 _B
MADC_ISOPD	8	RW	Enable the isolation of all control signals towards the MADC: 0 _B ... MADC connected 1 _B ... MADC isolated	1 _B
BG_EN	7	RW	Enable bandgap in MADC: 0 _B ... Disabled 1 _B ... Enabled	0 _B
RF_ISOPD	6	RW	Enable the isolation of all control signals towards the RF block: 0 _B ... RF connected 1 _B ... RF isolated	1 _B
ABB_ISOPD	5	RW	Enable the isolation of all control signals towards the analog baseband (BB) block: 0 _B ... BB connected 1 _B ... BB isolated	1 _B
CS_EN	4	RW	Enable channel set (CS): 0 _B ... CS is not used 1 _B ... CS is used In case of CSCI or CSCDS this bit is ignored. In the application at least the first channel set should be used by the host (CSC1:CS_EN= 1 _B).	0 _B
REPC	3:0	RW	Repetition factor for Channel set: RC= 2 ^{REPC} : 0 _D ... RC= 1 repetition 1 _D ... RC= 2 repetitions 2 _D ... RC= 4 repetitions ... 10 _D ... RC= 1024 repetitions 15 _D ... RC= 32768 repetitions In case of CSCI or CSCDS this bit is ignored.	0 _D

4.12 CCR0 - Chirp Control Registers 0

Registers CCRx are used to program the parameters for the modulation sequence. The main FSM will use those parameters to set internal timers and counter to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 30 Chirp Control Register 0

Table 33 CCR0: Register Description

Symbol	Bits	Type	Description	RST
TR_INIT1_MUL	23:22	RW	Timer multiplier factor for T_INIT1. Precise timing provided under CCR0:TR_INIT1.	0 _D
TR_INIT1	21:14	RW	Coefficient to calculate T_INIT1: 0 _D ... T _{SYS_CLK} From 1 _D to 255 _D the time delay for T_INIT1 is calculated as follows: $T_INIT1 = (TR_INIT1 \times 2^{TR_INIT1_MUL \times 8 + TR_INIT1_MUL + 3}) \times T_{SYS_CLK}$. See note below.	0 _D
REPT	13:10	RW	Repetition factor for shape sets in a frame: $RT = 2^{\text{REPT}}$: 0 _D ... 1 repetition 1 _D ... 2 repetitions 2 _D ... 4 repetitions ... 15 _D ... 32768 repetitions The host should program as default value 15_D.	0 _D
CONT_MODE	9	RW	After last repetition of RT, the CONT_MODE is enabled. 0 _B ... only in case if deep sleep power mode is enabled (CCR1: PD_MODE= 2 _D). The system clock is disabled internally. 1 _B ... goes to specified power mode (CCR1: PD_MODE) and after T_FED next shapes will run.	0 _B
TR_END	8:0	RW	Coefficient to calculate T_END. T_END Ramp End Delay defines the waiting time after generation of the ramp. $T_END = (TR_END \times 8 + 5) \times T_{SYS_CLK}$: 0 _D ... 5 * T _{SYS_CLK} 511 _D ... Max. delay	0 _D

Note:

These values are used for every up and every down-ramp.

4.13 CCR1 - Chirp Control Registers 1

Registers CCRx are used to program the parameters for the modulation sequence. The main FSM will use those parameters to set internal timers and counter to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 31 Chirp Control Register 1

Table 34 CCR1: Register Description

Symbol	Bits	Type	Description	RST
TR_FED_MUL	23:19	RW	Timer multiplier factor for frame end delay T_FED. Precise timing provided under CCR1:TR_FED. Note: only values TR_FED_MUL ≤ 10 _D are verified.	0 _D
TR_FED	18:11	RW	Coefficient to calculate T_FED: 0 _D ... T _{SYS_CLK} From 1 _D to 255 _D the time delay T_FED is calculated as follows: $T_FED = (TR_FED \times 2^{TR_FED_MUL \times 8 + TR_FED_MUL + 3}) \times T_{SYS_CLK}$	0 _D
PD_MODE	10:9	RW	After last RT repetition the chip enters this power mode for the time T_FED: 0 _D ... Keep power mode same (CSx, CSCx) 1 _D ... Idle Mode (CSI + CSCI) 2 _D ... Deep Sleep Mode (CSDS + CSCDS) 3 _D ... RSVD	0 _D
TR_START	8:0	RW	Coefficient to calculate T_START. T_START Ramp Start Delay defines the waiting time before generation of the ramp. $T_START = (TR_START \times 8 + 10) \times T_{SYS_CLK}$ 0 _D ... 10 * T _{SYS_CLK} 511 _D ... Max. delay	0 _D

4.14 CCR2 - Chirp Control Registers 2

Registers CCRx are used to program the parameters for the modulation sequence. The main FSM will use those parameters to set internal timers and counter to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 32 Chirp Control Register 2

Table 35 CCR2: Register Description

Symbol	Bits	Type	Description	RST
FRAME_LEN	23:12	RW	Frame length specifies the number of shape groups in a frame. When specified frame length is reached frame counter will be incremented and shape group counter reset: 0 _D ... 1 shape group 1 _D ... 2 shape group 4095 _D ... Max. frame length is 4095	0 _D
MAX_FRAME_CNT	11:0	RW	Maximum number of frames to be executed. When MAX_FRAME_CNT is reached, shape generation will stop and the chip will go into deep sleep power mode. The next frame can be triggered only after a reset (e.g. FSM_RESET). The frame generation can be stopped any time by the FSM reset (see MAIN: FSM_RESET). 0 _D ... Endless generation 1 _D ... 1 frame will be generated 4095 _D ... Max. number of frames generated is 4095	0 _D

4.15 CCR3 - Chirp Control Registers 3

Registers CCRx are used to program the parameters for the modulation sequence. The main FSM will use those parameters to set internal timers and counter to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 33 Chirp Control Register 3

BGT60ATR24C Registers

Table 36 CCR3: Register Description

Symbol	Bits	Type	Description	RST
TR_INIT0_MUL	23:22	RW	Timer multiplier for delay T_INIT0. Precise timing provided under CCR3:TR_INIT0.	0 _D
TR_INIT0	21:14	RW	Coefficient to calculate T_INIT0: $0_D \dots T_{SYS_CLK}$ From 1 _D to 255 _D the time delay for T_INIT0 is calculated as follows: $T_INIT0 = (TR_INIT0 \times 2^{TR_INIT0_MUL \times 8 + TR_INIT0_MUL + 3}) \times T_{SYS_CLK}$. See Note 3.	0 _D
TR_SSTART	13:9	RW	Coefficient to calculate T_SSTART. T_SSTART Sampling Start Delay Time after PA enable until 1 st trigger to MADC. $T_SSTART = (TR_SSTART \times 8 + 1) \times T_{SYS_CLK}$: $0_D \dots T_{SYS_CLK}$ 31 _D ... Max. delay	0 _D
TR_PAEN	8:0	RW	Coefficient to calculate T_PAEN. T_PAEN Delay Time after PLL Start to PA enable. $T_PAEN = TR_PAEN \times 8 \times T_{SYS_CLK}$: $0_D \dots$ RSVD 1 _D ... Min. delay 511 _D ... Max. delay	0 _D

Note:

1. One single step is equal to $8 \times T_{SYS_CLK}$ system clock cycles (= 100 ns)
2. The delay values are used for every up and every down-ramp
3. T_INIT0 and T_INIT1 should be programmed to a minimum value according to the ADC calibration time. See also Table 15 and Table 64.

4.16 PLLx [0...6] - Chirp Shape Registers

Registers PLLx, where x can be 1 to 4, are used to program the parameters for the modulation sequence inside the PLL local FSM. The main FSM will control the local PLL FSM to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 34 PLL Chirp Shape Registers 1-6

Table 37 PLLx#0 ... PLLx#6 Chirp Shape: Register Description

Symbol	Bits	Type	Description	RST
FSU[1..4] FSD[1..4]	23:0	RW	Chirp Start Freq Upchirp / Downchirp. SDM start frequency for the ramp generator: FSD = 0 _D for sawtooth shape In case FSD=0, RSD=0, and RTD=0, then the fast sawtooth shape is enabled. In all other cases the triangular shape is enabled.	0 _D
RSU[1..4] RSD[1..4]	23:0	RW	Ramp Step Upchirp / Downchirp. A ramp step is the RF frequency difference added to the actual frequency during single clock cycle time of $T_{SYS_CLK} = 12.5\text{ ns}$. In case the value is zero the RF frequency will be almost constant during the RTU/RTD time. bit (23) represents the sign for the ramp: 0 _D ... Upchirp 1 _D ... Downchirp	0 _D
TR_EDU[1..4] TR_EDD[1..4]	23:16	RW	Coefficients to calculate T_EDU and T_EDD, respectively. T_EDU and T_EDD are End of Chirp Delay applied after every Upchirp and Downchirp. If TR_EDU/D = 0: $T_EDU/D = 2 \times T_{SYS_CLK}$. If TR_EDU/D > 0: $T_EDU/D = (8 \times TR_EDU/D + 5) \times T_{SYS_CLK}$. 255D ... Max. delay	0 _D
RSVD	15:14		Reserved on register #2 and #6.	0 _D
RTU[1..4] RTD[1..4]	13:0	RW	Ramp Time Upchirp / Downchirp. RTU/D defines the number of clock cycles for the Upchirp (RTU) or Downchirp (RTD). The actual ramp time is $T_RAMP[U/D] = [RTU RTD] \times 8 \times T_{SYS_CLK}$. 0 _D ... Timer disabled. Disabling the timer is useful when doing Downchirp operation with fast down chirp enabled. 1 _D ... $T_RAMP = 100\text{ ns}$ 16383 _D ... $T_RAMP = 2^{14} \times 100\text{ ns} = 1.6383\text{ ms}$	0 _D
APU[1..4] APD[1..4]	23:12 11:0	RW	Number of samples for Upchirp (APU) or Downchirp (APD) for the results of a single ADC: 0 _D ... No sampling during chirp 1 _D ... Number of samples = 1 4095 _D ... Max. number of samples is 4095	0 _D

Note:

-IRQ FIFO interrupt is generated based on FIFO words. One FIFO word of 24 bit captures two ADC samples of 12 bit. For dual and quad ADC operation all samples result in 1 or more FIFO words. In single ADC mode, if an odd number of samples are selected, the FIFO interrupt will be generated after the following (even) sample. For single channel mode an even number of samples is recommended.

4.17 PLLx[7] – SCR Shape Control Register

Registers PLLx[7], where x can be 1 to 4, are used to program the parameters for the modulation sequence inside the PLL local FSM. The main FSM will control the local PLL FSM to run the expected modulation sequence in standalone mode (no external trigger required except the first one).

Figure 35 PLLx#7 SCR shape control register

Table 38 PLLx#7 SCR Shape Control: Register Description

Symbol	Bits	Type	Description	RST
TR_SED_MUL	23:19	RW	Timer multiplier factor for shape end delay T_SED. Precise timing provided under PLLx#7:TR_SED. Note: only values TR_SED_MUL ≤ 10 _D are verified.	0 _D
TR_SED	18:11	RW	Coefficient to calculate T_SED: 0 _D ... T _{SYS_CLK} From 1 _D to 255 _D the time delay T_SED is calculated as follows: $T_SED = (TR_SED \times 2^{TR_SED_MUL \times 8 + TR_SED_MUL + 3}) \times T_{SYS_CLK}$.	0 _D
PD_MODE	10:9	RW	After last shape repetition, FSM goes to a specified Power Down Mode (run this mode during T_SED): 0 _D ... Keep power mode same (CSx, CSCx) 1 _D ... Idle Mode (CSI + CSCI) 2 _D ... Deep Sleep Mode (CSDS + CSCDS) 3 _D ... RSVD	0 _D
CONT_MODE	8	RW	After last shape repetition REPS, FSM: 0 _B ... goes to a specified Power Down Mode and stop immediately 1 _B ... goes to a specified Power Down Mode and after T_SED it runs the next shapes	0 _B
RSVD	7:5	RW	RSVD	0 _D
SH_EN	4	RW	Enables the specific shape x (see Note 3): 0 _B ... shape is not used regardless if shape parameters of PLLx[1..7] are programed with values different from default value. 1 _B ... shape is used	0 _B

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
REPS	3:0	RW	Repetition factor for a single shape x: $RSx = 2^{REPSx}$: $0_D \dots RSx = 1$ repetition $1_D \dots RSx = 2$ repetitions $2_D \dots RSx = 4$ repetitions ... $15_D \dots RSx = 32768$ repetitions	0_D

Note:

1. When chirp shapes are not used FSU/RSU/RTU register fields must be programmed to 0_D (see also Table 37).
2. A “sawtooth” chirp can be defined by setting field $FSD = 0_D$, and programming the fields for Upchirp (see also Table 37).
3. At least the first shape needs to be enabled ($PLL1[7]:SH_EN = 1_B$)

4.18 PLL DFT0 Register

The setting in this register should be used when the CW mode is enabled (see also 10.3).

Figure 36 PLL DFT0 register

Table 39 PLL DFT0: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:6	RW	RSVD	0_D
BYPSPDM	5:2	RW	Word used when SDM bypassed	0_D
BYPSPDMEN	1	RW	$0_B \dots$ SDM module drives the PLL $1_B \dots$ Value of BYPSPDM drives the PLL	0_B
BYPRMPEN	0	RW	$0_B \dots$ Ramp generator enabled $1_B \dots$ Ramp generator disabled	0_B

4.19 RFT0 – RF Test Register 0

Register contains several bits used to enable dedicated paths for self-test.

Figure 37 RFT0 RF test register 0

Table 40 RFT0: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:22	RW	RSVD	0 _D
TEST_SIG_IF4_EN	21	RW	Enable the test signal output for IF channel 4	0 _D

TEST_SIG_IF2_EN	19	RW	Enable the test signal output for IF channel 2	0 _D
TEST_SIG_IF1_EN	18	RW	Enable the test signal output for IF channel 1	0 _D
RSVD	17:14	RW	RSVD	0 _B
RFTSIGCLK_DIV_EN	13	RW	Enable the RF test tone signal output to the baseband module: 0 _B ... Disable the divider output 1 _B ... Enable the divider output	0 _B
RFTSIGCLK_DIV	12:0	RW	RF test tone signal divider value: $f_{\text{RFTST}} = f_{\text{SYS_CLK}} / \text{RFTSIGCLK_DIV}$. 2 _D ... Min. divider value 8191 _D ... Max. divider value	8000 _D

4.20 RFT1 – RSVD

Reserved register

4.21 DFT0 – Design for Test Register 0

Register contains several bits needed for sensing eFuses.

Figure 38 DFT0

BGT60ATR24C Registers

Table 41 DFT0: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:15	RW	RSVD	0 _D
EFUSE_SENSE	14	W1C	Start EFUSE read out	0 _B
RSVD	13:5	RW	RSVD	0 _D
EFUSE_EN	4	RW	Enable EFUSE functionality	0 _B
RSVD	3:0	RW	RSVD	0 _D

4.22 DFT1 – Design for Test Register 1

Register contains one bit needed for sensing eFuses.

Figure 39 DFT1

Table 42 DFT1: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:10	RW	RSVD	0 _D
EFUSE_READY	9	R	EFUSE ready signal. Register CHIP ID #1 and CHIP ID #2 are valid if EFUSE_READY is set to 1.	0 _B
RSVD	8:0	RW	RSVD	0 _D

4.23 STAT0 - Status Register 0

The status register STAT0 provides the actual value of some specific internal states. However, it should be mentioned that for all status registers, STAT0, STAT1, and FSTAT, with the exception of the FIFO status and error flags, updates to each status register field can happen on different timing events relative to FSM states and the field content should be treated independently from one-another. In CW mode the status bits can be read properly after e.g. 100 μ s.

Figure 40 STAT0: Control FSM Status Register

Table 43 STAT0: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:14	R	RSVD	0 _D
SH_IDX	13:11	R	Actual chirp shape enabled by the FSM: 0 _D ... PLLU1 1 _D ... PLLD1 2 _D ... PLLU2 3 _D ... PLLD2 4 _D ... PLLU3 5 _D ... PLLD3 6 _D ... PLLU4 7 _D ... PLLD4	0 _D
CH_IDX	10:8	R	Actual channel set enabled by the FSM: 0 _D ... CSU1 1 _D ... CSD1 2 _D ... CSU2 3 _D ... CSD2 4 _D ... CSU3 5 _D ... CSD3 6 _D ... CSU4 7 _D ... CSD4	0 _D
PM	5:7	R	Power Mode is the current power mode status of FSM: 1 _D ... Active Mode 2 _D ... Interchirp Mode 3 _D ... Idle Mode 5 _D ... Deep Sleep Mode 0 _D , 4 _D , 6 _D , 7 _D ... RSVD	5 _D

			1 _B ... Up and running	
MADC_RDY	1	R	MADC status: 0 _B ... Status down 1 _B ... Up and running	0 _B
SADC_RDY	0	R	SADC startup / calibration status: 0 _B ... Status down 1 _B ... Up and running	0 _B

4.24 SADC_RESULT Sensor ADC Result Register

The sensor ADC register SADC_RESULT is used to monitor the SADC as well as to read out the output from the conversion.

Figure 41 SADC_RESULT register

Table 44 SADC: Register Description

Symbol	Bits	Type	Description	RST
RSVD	23:22	R	RSVD	0 _D
SADC_RAW	21:12	R	SADC Raw data (for test only)	0 _D
RSVD	11	R	RSVD	0 _B
SADC_BUSY	10	R	Shows if SADC is busy: 0 _B ... SADC not busy 1 _B ... SADC busy	0 _B
SADC_RESULT	9:0	R	10 bits measurement result. In case just 8 bits are converted, the 8-bit value is left-shifted by two (multiplied by 4). In case 9 bit are converted, the 9-bit result is left-shifted by 1 (multiplied by 2).	0 _B

4.25 FSTAT - FIFO Status Register

The global status register FSTAT is used to monitor the FIFO. It should be mentioned that for all status registers, STAT0, STAT1, and FSTAT, with the exception of the FIFO status and error flags, updates to each status register field can happen on different timing events relative to FSM states and the field content should be treated independently from one-another. In CW mode the status bits can be read properly after e.g. 100 μ s.

Figure 42 FSTAT Register

Table 45 FSTAT: Register Description

Symbol	Bits	Type	Description	RST
FOF_ERR	23	R	FIFO overflow error bit shows if more sample data are transferred to the FIFO than FIFO memory locations are available to store the data. The flag will be shown also in GSR0 as a part of FIFO over or underflow error bit FOU_ERR: 0 _B ... No FIFO overflow 1 _B ... FIFO had an overflow condition	0 _B
FULL	22	R	The FULL bit shows if the FIFO has fully filled up: 0 _B ... FIFO is not full 1 _B ... FIFO is full	0 _B
CREF	21	R	0 _B ... FIFO filling status below CREF 1 _B ... FIFO filling status is > CREF	0 _B
EMPTY	20	R	The FIFO empty bit EMPTY signals if the FIFO is empty: 0 _B ... FIFO stores at least one sample 1 _B ... FIFO is empty	1 _B
FUF_ERR	19	R	FIFO under flow error signals if the host was reading more sampling data from the FIFO than available. The flag will be shown also in GSR0 as a part of FIFO over or underflow error bit FOU_ERR: 0 _B ... No error 1 _B ... FIFO underflow occurred	0 _B
SPI BURST_ERR	18	R	In case of burst error this bit is set. Further details in the Note below and in chapter 5.85.8: 0 _B ... No error 1 _B ... Burst error occurred. Bit will be reset after HW or SW reset condition.	0 _B

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
CLK_NUM_ERR	17	R	Clock number error bit is set when SPI clocks do not fit the expected clock cycles. Further details in the Note below and in chapter 5.8: 0 _B ... No error 1 _B ... Burst error occurred. Bit will be reset after HW or SW reset condition.	0 _B
RSVD	16:14	R	Not used	0 _D
FILL_STATUS	13:0	R	FIFO filling status: 0x0 ... FIFO empty 0x1000 ... FIFO 50% filled 0x2000 ... FIFO full This bit field is for de-bugging only. It should not be evaluated while the MADC sampling and filing up the FIFO. It can be evaluated when the FSM status is held, for example, after an FSM reset or in a specific power mode, Deep Sleep e.g.	0 _D

Note:

FOF/FUF will be cleared after these resets:

- FIFO reset
- SW reset
- HW reset

4.26 Register CHIP ID #1

The unique CHIP ID consists of 48 bits. Register CHIP ID #1 provides the lower 24 bits of the ID.

Figure 43 **CHIP ID #1 Register**

Table 46 **CHIP ID #1: Register Description**

Symbol	Bits	Type	Description	RST
CHIP ID #1	23:0	R	Lower 24 bits of the CHIP ID (23:0)	

4.27 Register CHIP ID #2

The unique CHIP ID consists of 48 bits. Register CHIP ID #2 provides the upper 24 bits of the ID.

Figure 44 **CHIP ID #2 Register**

Table 47 **CHIP ID #2: Register Description**

Symbol	Bits	Type	Description	RST
CHIP ID #2	23:0	R	Upper 24 bits of the CHIP ID (47:24)	

4.28 **GSR0 - Global Status Register**

The global status register GSR0 is related to SPI read/write monitoring.

Figure 45 **GSR0 Register**

Table 48 **GSR0: Register Description**

Symbol	Bits	Type	Description	RST
RSVD	7:4	R	RSVD	1111 _B
FOU_ERR	3	R	Shows if FIFO overflow or underflow condition occurred. The error will be cleared after the following resets: FIFO reset or SW reset or HW reset: 1 _B ... Error condition occurred 0 _B ... No error	0 _B
MISO HS Read	2	R	SPI: MISO high speed mode activated	1 _B
SPI BURST_ERR	1	R	SPI burst error, defined within the SPI spec (see chapter 5.8): 0 _B ... No burst read/write error 1 _B ... Burst error	0 _B
CLOCK NUMBER	0	R	Defined within the SPI Spec:	0 _B

BGT60ATR24C Registers

Symbol	Bits	Type	Description	RST
ERROR			0 _B ... No clock number error 1 _B ... Error condition occurred	

5 Data Organization and SPI Interface

5.1 Data Header

The main FSM is capable of generating a data header to be attached to the actual radar raw data. The structure of the header is shown in Figure 46 and in Table 49. The data header can be disabled by controlling the bit SFCTL: PREFIX_EN (see chapter 4.8).

A sync-word is sent at the beginning of each acquisition to make the radar raw-data from each shape unique. This can be useful in case of broken communication with the application processor or in case of errors. Supposing the FIFO will generate a “FIFO overflow flag” the sync-word 0x000000 can be evaluated by the host controller and used to resync with the BGT60ATR24C and discard the data received before this sync word (if header or sync-word not used then the controller should reset the FIFO, discarding the actual FIFO data). On “FIFO underflow flag”, the received data bits from the host are 1111111111_B.

Following, the header includes also the frame counter and shape group counter, as well as the actual APU/APD value (see chapter 4.16) and temperature value.

Figure 46 Data header

Table 49 Data Header Description

Symbol	Reg	Bits	Description	RST
SYNC_WORD1	#0	23:12	The sync-word can be used to identify the start of a new chirp. In case the MADC will output also a sequence of 0x000000, to make the sync-word unique, the data from the MADC will be automatically changed to 0x001 before transferring it to the FIFO.	0 _D
SYNC_WORD0	#0	11:0	See SYNC_WORD1.	0 _D
FRAME_CNT	#1	23:12	Same as STAT1: FRAME_CNT (see chapter 4.5). <i>Note: FRAME_CNT info should not be used by the host when endless mode is enabled (please check CCR2:MAX_FRAME_CNT).</i>	0 _D
SHAPE_GRP_CNT	#1	11:0	Same as STAT1: SHAPE_GRP_CNT (see chapter 4.5).	0 _D
CHIRP_LEN	#2	23:12	Number of MADC samples inside the chirp (APU/APD value of related chirp).	0 _D
SADC_VAL	#2	11:2	10 bits of sensor ADC output data (e.g. temperature).	0 _D
CS	#2	1:0	Indicates the channel shape number to which the following sampling data belongs to.	
Data 0	#3	23:12	MSB data (see chapter 5.2).	
Data 1	#3	11:0	LSB data (see chapter 5.2).	

5.2 FIFO and Dataflow

The memory in the BGT60ATR24C is based on a FIFO. The FIFO consists of a circular shift register organized in 8192 words of 24 bits each. Four dataflow modes from MADC to the FIFO are supported by the FSM (see Figure 47):

- Mode 1: Only one ADC active (can be any ADC from 1 to 3)
 - Data from 1st sample, 12 bits, are temporarily stored in a buffer
 - When the 2nd sample, 12 bits, are available, both, 1st and 2nd, 24 bits, are stored into one data word
- Mode 2: Two ADCs active (can be any ADC from 1 to 3)
 - Data from active ADCs, 12+12 bits, are occupying one data word in the FIFO
- Mode 3: Three ADCs active
 - Data from first two channels are stored into a data word while data from third channel is buffered. On the consecutive trigger the buffered data and the one from first channel are stored in a data word while the data of the second channel is buffered. On the next trigger the buffered data plus the data from the third channel are stored in a third data word, etc.
- Mode 4: Four ADCs active
 - Data from active ADCs are occupying 2 subsequent datawords in memory

Data Organization and SPI Interface

		23	12	11	0
Mode 1	0x00	Trig1:ADC1		Trig2:ADC1	
	0x01	Trig3:ADC1		Trig4:ADC1

	0x01	Trig1:ADC3		Trig1:ADC4	
	0x02	Trig2:ADC1		Trig2:ADC2	
	0x02	Trig2:ADC3		Trig2:ADC4	

Figure 47 **FIFO organization**

Readout from the FIFO is done from the SPI block. Due to max frequency of SPI clock, 50 MHz, the readout rate from the FIFO is:

- $50 \text{ MHz} / \text{SPI Mode} / 24 \text{ bit} = 480 \text{ ns} = 40 \text{ cycles (in the 80 MHz domain)}$

Readout from the FIFO should be executed from the host controller using memory address with correct data length and SPI burst reads. Data length can be derived from the data header or based on the “sync-word”.

Note:

An illegal write to memory address space will lead to lost FIFO data!

5.3 SPI – Serial Peripheral Interface Module

The SPI is the basic communication interface between the host and the BGT60ATR24C. It enables the host to read to, or write (program) from the registers as well as reading from the FIFO.

Figure 48 SPI module

The device supports two different SPI modes,

- Normal SPI
- Quad-SPI (QSPI)

In order to enter the expected mode, do the following.

Normal SPI

BGT60ATR24C features four I/O pins for SPI communication and one for chip reset. DIO[x] pins are pulled up to logic high inside the pad.

- CS_N to be connected to $\overline{SS}$ of the SPI master
- CLK to be connected to CLK of the SPI master
- DIO0, DI to be connected to MOSI of the SPI master
- DIO1, DO to be connected to MISO of the SPI master
- DIO2 not available in normal SPI mode
- DIO3 to be connected to reset

Table 50 SPI pins

Pin Name	Standard SPI Mode Function	Remarks
CS_N	CS_N	Chip select or Slave Select
CLK	CLK	SPI clock
DIO0	DI	HiZ, bidirectional
DIO1	DO	HiZ, bidirectional
DIO2	N.A.	Not available in normal SPI mode
DIO3	RESET	HiZ, bidirectional

The SPI interface can be clocked up to 50 MHz. To meet the timing requirements for higher SPI clock frequencies (e.g. > 25MHz) BGT60ATR24C offers an additional high speed mode (SFCTL:MISO_HS_RD) which increases the timing budget on SPI master side by sending out data via DO with the rising edge instead of the falling edge of the CLK.

Data Organization and SPI Interface

Quad SPI (QSPI)

After SPI_CSN is active low, the address is transferred. Therefore, the first working edge of SPI_CLK transfers the four upper MSB address bits from SPI_DIO[3:0] into the shift register. On the second working edge of SPI_CLK, the four LSB address bits are transferred into the shift register.

In case if the received address in the shiftregister is address < 0xC0, then the QSPI mode is activated and the normal SPI mode is disabled during SPI_CSN is active low.

An address $\geq 0xC0$ is not allowed.

For details of Quad SPI operation see chapter 5.9

5.3.1 Standard SPI Timing

The timing diagram for normal SPI mode (SFCTL: MISO_HS_RD = 0_b) is presented in Figure 49. A SPI transfer is started with a falling edge of chip select signal CSN generated by the SPI master. At the same time the SPI master shall drive the level of the data input signal DI /MOSI (Master Output Slave Input) according to the first bit. Also with the falling edge of the chip select signal CSN the SPI slave applies the level of the data on the output signal DO / MISO (Master Input Slave Output) according to the first bit which shall be transferred to the SPI master, the level becomes stable after the period $t(ds)$. The SPI master has to wait for the time $t(L)$ before the clock signal CLK can be generated.

With the rising edge of CLK the SPI slave captures the level of DI. The SPI master must keep the DI level stable for $t(sis)$ before and for $t(sih)$ after the rising edge of CLK to ensure valid setup and hold time of the SPI slave. With the falling edge of CLK the SPI master shall set the level of DI according to the next bit the master wants to send.

The SPI master is supposed to read the level of DO with the rising edge of CLK. The SPI slave keeps the DO level stable for $t(soh)$ after the falling edge of CLK. With the falling edge of CLK the SPI slave drives the level of DO according to the next bit, DO becomes stable after latest $t(sov)$.

After the last bit has been transferred and CLK has gone to low level, the SPI master must set CSN to high level to stop the transfer. The master must take care that the period between the last rising edge of CLK and the rising edge of CSN is not shorter than $t(T)$. Within the period $t(dh)$ after the rising edge of CSN the SPI slave drives DO to high impedance state again.

Figure 49 SPI interface timing diagram for SFCTL: MISO_HS_RD = 0_b

Data Organization and SPI Interface

Figure 50 SPI interface timing diagram for SFCTL: MISO_HS_RD = 1_b

BGT60ATR24C can operate at SPI clock frequencies up to 50MHz, but the maximum achievable SPI clock frequency is limited by DI related setup and hold times of SPI master and SPI slave. If for example the SPI master requires a longer setup time than $T/2 - t(\text{sov})$, the SPI clock speed in normal SPI mode must be reduced. Alternatively, BGT60UTR11DAiP can be switched to SPI high speed mode by setting SFCTL: MISO_HS_RD = 1_b.

The timing diagram for high-speed SPI mode is presented in Figure 50. In this mode the SPI master is still supposed to capture the level of DO with the rising edge of CLK. The SPI slave keeps the level of DO stable for $t(\text{soh})$ after the rising edge of CLK, and then sets the level of DO according to the next bit which is send out.

Table 51 SSPI Timing Requirements, VDDD= 1.71 to 1.89 V, T_b = -40 to +105°C

Spec	Symbol	Unit	Value			Number	Condition
			Min	Typ	Max		
Parameter			Min	Typ	Max		
SPI clock period: 50 MHz, with 1% clock jitter	T	ns	20			5.3.1	
Clock high	t(ch)	ns	9.0			5.3.2	
Clock low	t(cl)	ns	9.0			5.3.3	
Slave input setup	t(sis)	ns	5.0			5.3.4	
Slave input hold	t(sih)	ns	5.0			5.3.5	
Slave output valid	t(sov)	ns			15.0	5.3.6	(see Note 2)
Slave output hold	t(soh)	ns	1.0			5.3.7	
Lead time before the first working clock edge occurs	t(L)	ns	9.0			5.3.8	
Tailing time after the last working clock edge	t(T)	ns	1			5.3.9	
Data setup time after the DO goes in low impedance state	t(ds)	ns			5.0	5.3.10	Defined by design
Data hold time before the DO goes in high impedance state.	t(dh)	ns			5.0	5.3.11	Defined by design

Data Organization and SPI Interface

Note:

1. If *SFCTL: MISO_HS_RD* is not set properly then data read on MISO may not be correct.
2. The timing is ensured for worst case condition: $V_{DDD} = 1.71\text{ V}$, $T_b = +70^\circ\text{C}$, output load of $C_{load} = 50\text{ pF}$.

5.3.2 Logic Levels

The digital inputs and outputs are fully CMOS compatible (reported in Table 52). All IO input / output timings are based on 50% voltage reference levels (see Figure 51). I/O interfaces are shown in Figure 54, input pins, and Figure 55, output pins, which include internal pull-ups.

Figure 51 AC timing input/output reference levels

The input logic hysteresis prevents input buffers from oscillation. The minimum hysteresis range V_{HYST} is in between the lower ($0.3 \times V_{DDD}$) and upper logic level ($0.7 \times V_{DDD}$) boundaries (see Figure 52). Above $0.7 \times V_{DDD}$ the input signal is a logical '1' while below $0.3 \times V_{DDD}$ it is a logical '0' regardless of hysteresis. Due to temperature drifts and device variation the hysteresis range V_{HYST} can be up to $0.7 \times V_{DDD}$ or down to $0.3 \times V_{DDD}$ but typically around $0.5 \times V_{DDD}$. Parameters are reported in Table 52 and Table 53.

Figure 52 Logic input levels and hysteresis

The digital output pads have a fixed output pad strength that gives a specific slew-rate for rising signals, dV_{TR} , and falling signals, dV_{TF} (see Figure 53). Minimum slew rates were simulated considering a total capacitive load of 15pF. Results reported in Table 52 and Table 53.

Figure 53 Rise/Fall Time, Slew Rate specified between $0.2 \times V_{DDD}$ and $0.8 \times V_{DDD}$

Data Organization and SPI Interface

Table 52 **Logical Levels for Pins SPI_CLK, CS_N, DI, DO, DIO2, DIO3**, VDDD= 1.71 to 1.89 V, T_b = -40 to +105°C, ambient temperature not below -40°C; all voltages with respect to VSSD digital ground, positive current flowing into pin (unless otherwise specified)

Figure 55 Interface for output pins IRQ, DI, DO, DIO2, DIO3

5.4 Overshoot and Undershoot Waveform Definition

During operation the applied signals and supply levels should not exceed absolute maximum DC levels specified in datasheet. Digital signals can have positive or negative overshoots due to inductive and/or capacitive loads. The following Table 54 reports the allowed overshoot timings and signal levels for all logic signals.

Table 54 Overshoot and Undershoot Signal Levels

Spec	Symbol	Unit	Value			Number	Condition
			Min	Typ	Max		
Maximum absolute overshoot voltage level	Vos	V			VDDD+ 0.5 V	5.4.1	see Note:
Maximum absolute undershoot voltage level	Vus	V			VSS - 0.5 V	5.4.2	see Note:

Note: Maximum pad current not exceeding ± 5 mA (see also Table 53). No slew rate limitation existing on digital signals for overshoots / undershoots.

5.5 IBIS Model

A BGT60ATR24C IBIS Model is available under NDA upon request. It is based on timing simulations. In order to better reflect the real timing behavior, different pad models for input/output signals are used and summarized in Table 55. The driver strength for all pads are fix (PRG0=0).

Table 55 IBIS Pad Types and Models (see Ibis model)

Pin	Ibis PAD Model
CSN	IN: MODEL_654_7345_110
CLK	IN: MODEL_654_7345_110
DIO0 / DI	IN: MODEL_8138_4982_52 OUT: MODEL_8138_4982_59
DIO1 / DO	IN: MODEL_8138_4982_52 OUT: MODEL_8138_4982_59
DIO2	IN: MODEL_8138_4982_52 OUT: MODEL_8138_4982_59
DIO3 / Reset	IN: MODEL_8138_4982_52 OUT: MODEL_8138_4982_59
IRQ	OUT: MODEL_8138_4982_55

5.6 SPI Functionality

Each word transferred over the SPI bus has a length of 1 command byte + 3 data Bytes. The communication is done bitwise. First the address is transferred with MSB first. The address is followed by the R/W-bit and then followed by the data which is sent MSB first, too. At the same time, while command byte is received, a freely from system level configurative global status register (8 bits, GSR0) is serial shifted out on DO (MSB first). On the following 24 clock cycles the selected register content is shifted out on DO, MSB first.

Depending on sent R/W-bit there are two different operation modes available, the write mode and the read mode. Every write mode is a read mode too.

Write-Mode

After the start condition the desired address is sent. The address is 7 bits long followed by a bit that is a data direction bit (read/write). A one indicates a write operation (see Figure 56).

Figure 56 SPI timing write mode

BGT60ATR24C

60 GHz radar sensor

Data Organization and SPI Interface

Read-Mode

After the start condition, the desired address is sent like in the write operation. A zero of the R/W-bit indicates a read access. The data on DI after the command byte may contain any value. The DO behavior is the same as in write mode.

Figure 57 SPI timing read mode

5.7 SPI Burst Mode

The burst mode can be used to read or write out several registers or some data from the FIFO instead of reading just single registers or data. The burst mode command is sent by the host. The burst mode command consists of several bit fields and is shown in Figure 58.

Figure 58 Burst mode command

The following Table 56 shows a detailed description on the burst mode command bit fields.

Table 56 Burst Mode Command Bit Field Description

Bit field	Bit	Description	RST
ADDR	31:25	To enter the burst mode the following address is used: 0x7F ... request the burst read/write.	
RW	24	Read/Write register access: Fixed to 1 _B ... write to address 0x7F	
SADDR	23:17	Starting address where the burst starts processing: < 0x62 Register access == 0x62 FIFO access > 0x62 Reserved - Address is incremented automatically inside a burst.	
RWB	16	Burst read or write: 0 _B ... Perform a read burst	

Data Organization and SPI Interface

Bit field	Bit	Description	RST
		1 _B ... Perform a write burst, (writes to FIFO not supported)	
NBURSTS	15:9	Number of processed data blocks: 0x00... “unbounded” burst accesses 0x01 to 0x7E ... number of words to transfer	

Note:

A single data block is 24 bits width for both, the sampling memory and the registers.

Burst Mode Operation

After the start condition the 32 bits burst mode command is sent from the SPI master on DI. At the same time, the status register GSR0 (four 1_B bits + four status bits) followed by 24 padding bits set to 0_B is shifted out on DO. After the command sequence is done, the register/FIFO data is shifted out to the SPI master on DO. In burst write mode, the register data to be written is shifted in from the SPI master (application processor e.g.).

Burst Mode Read Sequence:

In the read sequence, the SPI master reads from the device.

Figure 59 Burst mode read sequence

Burst Mode Write Sequence:

In the burst write mode, the SPI master writes to the device.

Figure 60 Burst mode write sequence

Sampling Data Arrangements in Data Blocks

The data from the FIFO are streamed out during the burst read request, starting from the FIFO address zero. The 1st ADC is the ADC channel with the lowest channel number. As far as the sampling memory is organized in 24 bits

Data Organization and SPI Interface

and up to four ADC channels are selectable through the ADC channel selection bits (CSx: BBCH_SEL, see chapter 4.10) the data blocks are arranged as follows.

In case a single ADC is selected, the data blocks are shown in Figure 61.

Figure 61 Single ADC channel selected

In case two ADCs are selected, the data blocks are arranged as shown in Figure 62.

Figure 62 Two ADC channels selected

In case three ADCs are selected, the data blocks are arranged as shown in Figure 63.

Figure 63 Three ADC channels selected

In case four ADCs are selected, the data blocks are arranged as shown in Figure 64.

Figure 64 Four ADC channels selected

Example: Burst Mode Read Sampling Memory Sequence

The following burst mode command is sent from the host to initialize the burst mode to read from the FIFO an undefined number of sampling data:

BMCMD_RS = (ADDR = 0x7F, RW = 0x01, SADDR = 0x62, RWB = 0x0, NBURSTS = 0)

REMARK:

For each burst read request to the sampling memory, the sampling-memory address pointer is reset to the initial value. So that memory can be read out from the beginning until the application processor stops burst reading.

Example: Burst Mode Read Registers Sequence

The following burst mode command is sent from the host to initialize the burst mode to read out 10 registers starting from register address 3:

BMCMD_RR10 = (ADDR = 0x7F, RW = 0x01, SADDR = 0x3, RWB = 0x0, NBURSTS = 10)

5.8 SPI Error Detection

SPI BURST_ERR and CLK_NUM_ERR (see also Table 45) will be cleared after these resets:

- SW reset
- HW reset

SPI BURST_ERR and CLK_NUM_ERR are reported in the global status bits of the next SPI transaction and latched as sticky bits in the FSTAT register.

In order to understand if the captured sample data are corrupted, the host can evaluate the bit field CLK_NUM_ERR and SPI BURST_ERR as reported in Table 57.

Table 57 SPI BURST_ERR and CLK_NUM_ERR Definitions

Length Range	Transaction	SPI BURST_ERR	CLK_NUM_ERR	Behavior on read/write
0	Null command	0 _B	0 _B	Ignored
1-31	Short length error in single	0 _B	1 _B	Command ignored
>32	Long length error in single	0 _B	1 _B	Extra bits ignored
1-31	Short length error in SPI burst header	0 _B	1 _B	Command ignored

Data Organization and SPI Interface

Only 1 command is supported:

- Command = same as read address (either registers or FIFO). An address $\geq 0xC0$ is not allowed.
- During burst read, the provided address will be incremented internally, the following data are taken from the address related location ($<0x62$ read from register, afterwards read from FIFO)

QSPI can be

- burst read of registers (≥ 2 wait cycles)
- burst read of FIFO (≥ 2 wait cycles)
- burst read over $0x62$ border (≥ 2 wait cycles)

5.10 Hardware Reset Sequence

After power up, the chip is not in a default reset condition and requires a dedicated HW reset as described below. Only after the HW reset also other reset sequences can be triggered via SPI (e.g. SW, FIFO and FSM- reset). For such SPI triggered resets an external OSC_CLK (see Table 2) needs to be applied, while the HW reset does not require any external OSC_CLK.

HW Reset Sequence: While CS_N is = '1_B' DIO3 must perform a $1_B \rightarrow 0_B \rightarrow 1_B$ transition

The behavior is presented in Figure 66 with:

$T_{CS_BRES} = 100 \text{ ns}$

$T_{RES} = 100 \text{ ns}$

$T_{CS_ARES} = 100 \text{ ns}$

Figure 66 Hardware reset Sequence

5.11 Software Triggered Resets

Besides the hard reset, three reset sequences are supported and can be triggered in the ISO register (see also 4.2). They are defined according to the following hierarchy:

Soft reset → FIFO reset → FSM reset

- **Software Reset**

- Resets all registers to default state
- Resets all internal counters (shape, frame e.g.)
- Perform FIFO reset
- Performs FSM reset
- A delay of 100 ns after the SW_RESET is needed before the next SPI command is sent

- **FIFO Reset**

- Reset the read and write pointers of the FIFO
- Array content will not be reset, but cannot be read out
- FIFO empty is signaled, filling status = 0
- Resets register FSTAT
- Performs an implicit FSM reset

- **FSM Reset**

- Resets FSM to deep sleep mode
- Resets FSM internal counters for channel/shape set and timers
- Resets STAT0 and STAT1 register
- Reset PLL ramp start signal
- Reset PA_ON
- Terminates frame (shape and frame counters incremented although maybe not complete)

6 PLL Domain Functional Specification

The PLL is designed to generate high performance frequency chirps in the range of 58 GHz to 62 GHz. The modulation is performed inside the PLL bandwidth (in-band-modulation) with an analog charge pump based fractional-N RF-PLL architecture. It furthermore features a shape generator with high flexibility to allow different ramp shapes and duration times. The loop requires a low noise reference clock with a nominal frequency of 80 MHz.

6.1 PLL Interfaces and Clock Distribution:

Figure 67 shows the interfaces to the PLL and the distribution of the 80 MHz reference clock.

6.2 Reference Clock Distribution

The external 80 MHz reference clock signal is provided via a short, low jitter path directly to the input of the PLL analog part. From there the clock is distributed to the reference clock buffer of the PLL and also via another path to the STS, which is the defined interface between the PLL analog and the digital part. These paths are independent from each other since the clock provided through the STS to the output of the PLL macro ("osc_clk2dig") serves as the clock for the main FSM. It must be available even when the PLL is put into power down. Therefore, the usage of internally generated supplies of the PLL is avoided. The main FSM clock can be gated via a dedicated register bit called PACR1.OSCCLKEN (see chapter 4.6) which quiets the clock path already at its beginning.

Figure 67 PLL and 80 MHz clock interface to the main FSM

6.2.1 Interfaces to the PLL

Most static settings and control signals dedicated to the analog part of the PLL are treated as asynchronous signals and are passed from the register bank to the STS of the PLL. This applies to digital signals that are not timing critical. Ramp generation parameters provided from the main FSM to the digital part of the PLL are registered inside the PLL digital. The start signal of the ramp also acts as a synchronization signal of the ramp parameters. This is required since the PLL digital runs on the divided clock of the PLL which ensures a known and synchronous timing relation between the sigma-delta bit stream and the analog part of the PLL that realizes the ramping behavior. The divided clock is only available if the PLL macro and the VCO are activated. Other control signals from PLL digital to the analog part are kept asynchronous. In order to close the PLL loop the analog part of the PLL core has interfaces to the RF-macro where the VCO and a part of the divider chain are located.

6.3 PLL Parameters and Specification

Table 58 summarizes the target parameters of the PLL-based frequency generator.

Table 58 PLL Specifications, VDDPLL= 1.71 to 1.89 V, VDDLDF= 2.5 to 3.63 V, T_b = -40 to +105°C

Spec	Symbol	Unit	Value			Number	Condition/Note
			Min	Typ	Max		
Parameter							
Reference Clock							
Reference Frequency	f _{ref}	MHz	75	80	85	6.3.1	f _{ref} = f _{SYS_CLK} See 2.2 78 MHz not allowed
Rise and Fall Time of Reference Clock	t _{rs, fs, clk}	ns			6	6.3.2	1.8 V CMOS clock
PLL Chirp Parameters							
Output Frequency Range	f _{RF}	GHz	58		62	6.3.4	Range depends on the VDDLDF value
Continuous FM-Chirp Bandwidth	BW	GHz	0		4	6.3.5	PLL tuning range
VDDLDF Range	VDDLDF	V	2.5		3.63	6.3.6	4 GHz modulation BW requires at least VDDLDF= 3.3 V
Chirp slope	Slope	MHz/μs			400	6.3.7	
Frequency Ramp Linearity Error	Error	%			1	6.3.8	For 2 GHz BW minimum See 6.3.1, Figure 13, Table 15
Frequency Ramp Settling Time (fast chirp feature active)	t _{PLL, settle}	μs		5		6.3.9	See 6.3.2
PLL Phase Noise Single Sideband	PN _{PLL, 100kHz}	dBc/Hz		-80	-70	6.3.10	@100 kHz offset

6.3.1 Frequency Ramp Linearity Definition:

Frequency ramp linearity error is defined to be <1% of the FM-chirp bandwidth. The linearity error is calculated as the deviation from an “ideal” frequency ramp. The specification needs to be fulfilled after the frequency ramp settling time (see also chapter 3.3). The assumed worst-case FM-chirp bandwidth for linearity evaluations is 2 GHz.

Figure 68 Frequency linearity definition

The max. frequency error expected, assuming 2 GHz minimum BW and a max. deviation of 1%, will be 20 MHz.

6.3.2 Frequency Ramp Settling Time

It is the time required by the PLL to damp undershoot and overshoot in case of saw-tooth shapes. A qualitative view is shown in Figure 69. See chapter 3.3 for a more detailed definition of the timings.

Figure 69 Chirp settling time

7 Analog-RF Domain Functional Specification

In the analog functional specification all analog components like RF frontend (RF FE), baseband amplifiers, and filters are described in more details.

The register definitions for the components are in chapter 4.

Figure 70 Analog domain simplified block diagram

7.1 RF Frontend (RF FE)

In the RF frontend, all features to enable the radar functionality are implemented.

Figure 71 Simplified block diagram of BGT60ATR24C transceiver frontend

7.1.1 On-Chip Analog Sensor Output

The analog sensor outputs are connected to the SADC. See chapter 4.9 for the SADC input configuration. See also chapter 4.9 for enable pins definition.

7.1.2 RF FE Specifications

In the table below the target specifications for the RF frontend measured at die PAD interface.

Analog-RF Domain Functional Specification

Table 59 RF FE Specifications, min and max values cover the specified frequency range, f_{RF} = 58.0 to 62.0 GHz. Temperature range, T_b = -40 to +105°C, and voltage supply range, V_{DDRF} = 1.71 to 1.89 V (unless otherwise specified)

Spec	Symbol	Unit	Value			Number	Condition

- 1) power to voltage gain
- 2) on Evalboard

Output power can be evaluated by sampling the level of the peak detector at the output of the TX power amplifier. This signal has to be compared to a reference to de-embed thermal drift of the sensor. Therefore, both signals on channel SADC:CH12 & CH14 (pd_out) and SADC:CH11 & CH13 (pd_outx) are sampled by the SADC in two consecutive steps (pd_outx – pd_out). See chapter 4.9.

Note: The 80 MHz spur clock signal could affect the SADC the readout ($\pm 10 \text{ mW}$). In order to have a more stable read out for the sensors, 16 avg for each sensor measurement are recommended.

7.2 Analog Baseband: Amplifiers and Filters

The baseband amplifiers and filters adjust the IF signals to fulfill the system requirements. They set the signal levels to drive full scale the ADC inputs without clipping.

Figure 72 Baseband amplifiers and filters block diagram

7.2.1 Baseband Characteristics

The baseband block consists of four channels. Each channel consists of a high pass filter (HPF), a variable gain amplifier (VGA), and anti-aliasing filter (AAF) plus a driver for the ADC (see Figure 74).

Figure 73 Baseband characteristic

Analog-RF Domain Functional Specification

The high pass filter is used in order to remove the DC-offset at the output of the RX mixer and also suppress the reflected signal from close in unwanted targets (radome, e.g.).

7.2.2 Baseband Requirements

The high pass filter can be tuned to accommodate different cutoff frequencies f_{cHPF} according to different modulation parameters. As presented in Table 60 four different settings are possible.

Given the expected power levels the radar system will deal with, the HPF should not degrade the linearity of the system.

Figure 74 Baseband simplified block diagram, one for each channel

After the AC-coupling, the IF signals are amplified by the first amplifier stage. The first stage shows a selectable voltage gain of 18 or 30 dB. The gain can be adjusted in the VGA in 6 steps of 5 dB each up to a maximum gain of 30 dB. The VGA is followed by a two-stages, four-poles antialiasing filter. The signal is then applied to an ADC driver amplifier, which has a gain of 1. Overall, the baseband chain can be set to a maximum gain of 60 dB.

The specific parameters of the baseband chain are summarized in Table 60, Table 61 and Table 62.

Table 60 High Pass Filter Selection. VDDRF= 1.71 to 1.89 V, $T_b = -40$ to $+105^\circ\text{C}$

Spec	Unit	Value			Number	Description

LPF_Order			2 nd		7.2.9	Four poles, by design
LPF_Flatness	dB		1		7.2.10	In band flatness, defined by design

8 MADC Domain Functional Specification

The multichannel ADC (MADC) block consists of four differential SAR ADCs. The four ADCs are capturing the four differentials IF output signals from the baseband and convert them into a digital representation of the same. The one 1.5 V supply (VDDC) is internally generated by a dedicated LDO (see Figure 5). This block is enabled by bit MADC_EN in Table 30, parameters are set in 4.3. Each channel of the MADC can be enabled/disabled together with the respective baseband channel by the bits BBCH_SEL in Table 30. To simplify the dataflow to the memory the ADC channels to be used can be selected via the BBCH_SEL in Table 30. See also APU and APD in Table 37 and paragraph 5.2.

Figure 75 MADC block diagram

8.1 MADC Supply Voltage Requirements

The voltage supply to the ADC domain is provided on pin VDDA and the output of the internal ADC reference voltage is provided on pin VAREF. In order to filter out the voltage ripples due to switching effects a low ESR bypass capacitor with a value of $C_{b2} = 470 \text{ nF}$ should be used on the PCB.

MADC Domain Functional Specification

Figure 76 MADC input pin requirements

Both ground connection pins VSSA and VAGND share the same analog ground connection on PCB. The bypass capacitors should be mounted as close as possible to those pins.

Table 63 MADC Voltage Reference, VDDA= 1.71 to 1.89 V, T_b = -40 to +105°C

Spec	Symbol	Unit	Value			Number	Condition
			Min	Typ	Max		
Positive reference voltage with respect to VAGND, generated internally	VREFP	V	1.14	1.2	1.26	8.1.1	
Negative analog reference voltage	VAGND	V	0		0.1	8.1.2	Refers to board design ground plane

8.2 MADC Specifications

Table 64 below specifies the ADC parameters. The numbers include one over-conversion. All parameters are only valid with executed startup calibration. No parameter is targeted for production test.

Note:

$$f_{ADC_CLK} = f_{SYS_CLK}$$

REMARK:

If the ADC starts sampling before the bandgap is powered up (BG_EN in Table 32), the results will show some gain errors. To avoid this, follow the bandgap power up timing presented in chapter 8.4.

MADC Domain Functional Specification

Table 64 MADC Specifications, VDDA= 1.71 to 1.89 V, T_b = -40 to +105°C¹⁾

Spec	Symbol	Unit	Value			Number	Condition
Parameter			Min	Typ	Max

Startup calibration time ^{2,3)}	T _{SUCAL}	Counts of clk	3361	6049	16801	8.2.10	ADC0: DSCAL= 0 _B Typical conditions: ADC0: STC=1 _b ADC0: MSB_CTRL= 1 _b
Setup time common mode input voltage	T _{VCM}	μs			1	8.2.11	
Power supply Rejection Ration on VDDS	PSRR	dB	20			8.2.12	

1) Parameters ensured by design

2) $T_{SUCAL} = (1792 * 2^A(ADC0:STC) + 896 * ADC0:MSB_CTRL + 1569) * 1/f_{SYS_CLK}$

3) Overall wake up time when calibration time is enabled = T_{WUADC} + T_{SUCAL}

8.3 MADC Timing Diagrams

The interface is fully synchronized to the main clock. Figure 77 shows the 12 bits conversion timing in case of one tracking and no oversampling. Thus, the maximum speed of the ADC is set to 2.5 MSps at 80 MHz clock input. Figure 77 shows the SAR ADC timing.

MADC Domain Functional Specification

Important: all configuration signals must be stable during a running conversion (between start_adc and one cycle before eoc).

Figure 77 SAR ADC conversion timing diagram, 12 bit

8.4 MADC Startup Sequence

The following figure shows the startup sequence for the complete ADC.

Figure 78 MADC start-up timing constraints

After a reset and trigger from the host, the FSM will move from the deep sleep mode into the idle mode. Here T_{WKUP} represents the overall time required by the bandgap to settle and it is the longest time required in the settling of the ADC.

The following Table 65 shows the start-up timing constraints:

MADC Domain Functional Specification

Table 65 MADC Timing Constraints, VDDA= 1.71 to 1.89 V, T_b = -40 to +105°C

Spec	Symbol	Unit	Value			Number	Condition
			Min	Typ	Max		
Parameter							
Wake up time	T _{WUADC}	μs		8.25		8.4.1	@80 MHz
Setup time common mode input voltage	T _{VCM}	μs			1	8.4.2	
Wake-up time for bandgap and bandgap reference buffer	T _{WU}	μs	300		1000	8.4.3	

8.5 MADC Conversion Rate

The ADC clock input is f_{ADC_CLK}= f_{SYS_CLK}= 80 MHz and is derived from the system clock.

A conversion can include three different phases:

- Sampling
- Conversion
- Tracking

8.5.1 Sampling

During the first phase, the analog input voltage is sampled onto the input capacitor. The duration is controlled using the ADC0_STC bits. The following Table 66 shows the link between the register value ADC0_STC the clock periods STC_NUM and the sampling time.

Table 66 ADC0:STC Value Table (see chapter 4.3)

	Sampling clock periods	Sampling time in ns (f _{ADC_CLK} = 80 MHz)
ADC0:STC	STC_NUM	t _{sample}
0 _D	4	50
1 _D (default)	8	100
2 _D	16	200
3 _D	32	400

The sampling time is calculated as: N_{sample} = STC_NUM

8.5.2 Conversion

The charge from the sampling capacitor is redistributed to 13 + 2 capacitors. To identify the LSB bits of the result, 13 clock cycles are needed.

To identify the MSB bit of the result, one or two clock cycles are used, depending on register setting ADC0_MSB_CTRL:

- In case of MSB_CTRL is set to 0_B, just a single (1) clock cycle is used
- In case of MSB_CTRL is set to 1_B, two (2) clock cycles are used

The redistribution time is calculated as:

$$N_{\text{conv}} = (13 + 2 + \text{ADC0: MSB_CTL})$$

8.5.3 Tracking

In this mode, the ADC performs a single sample conversion followed by several tracking conversions, depending on the setting of bits ADC0: TRACK_CFG:

Table 67 ADC0: TRACK_CFG Value Table

ADC0: TRACK_CFG	Additional conversions TRACK_CFG_NUM	Remarks
0 _D	0	
1 _D	1	Default
2 _D	3	
3 _D	7	

The duration of one tracking conversion is:

$$N_{\text{track}} = 8$$

The duration of all tracking conversions for a single result is then:

$$N_{\text{track_all}} = 8 \times \text{TRACK_CFG_NUM}$$

8.5.4 ADC Conversion Rate

Based on what is defined in 8.5.1, 8.5.2 and 8.5.3 the following cycles are defined for a single conversion:

$$N_{\text{ADC_CONV}} = N_{\text{samp}} + N_{\text{conv}} + N_{\text{track_all}}$$

with N_{samp} the number of sampling, N_{conv} conversion and N_{track} tracking cycles, respectively.

All ADCs are synchronized to $f_{\text{SYS_CLK}}$.

8.5.5 ADC Sampling Rate

The ADC sampling rate is controlled by the ADC0: ADC_DIV value (see Table 22). The sampling rate of the ADC is given then by $f_{\text{ADC_SAMP}} = f_{\text{ADC_CLK}} / \text{ADC_DIV}$. ADC0: ADC_DIV value needs to be greater than the number of clock cycles needed by a single ADC conversion as described in 8.5.4.

The sampling rate of the ADC is:

$$f_{\text{ADC_SAMP}} = f_{\text{ADC_CLK}} / \text{ADC_DIV}$$

$$\text{with } \text{ADC_DIV} > N_{\text{ADC_CONV}}$$

Table 68 **ADC Sampling Rate**, VDDA= 1.71 to 1.89 V, T_b = -40 to +105°C

Spec	Symbol	Unit	Value			Number	Condition
			Min	Typ	Max		
Parameter							
ADC sampling rate	f _{ADC_SAMP}	MHz		2	4	8.5.1	
Effective number of bits resolution	ENOB	1		10.5		8.5.2	

9 SADC Domain Functional Specification

The Sensor ADC (SADC) is a single channel single-ended 8 bits SAR ADC.

The sensor ADC can be used to monitor the temperature output as well as the power detector outputs from the transmitter channels. Conversion data can be read out through the SADC register (see also chapter 4.24). The data can be added also to the header of MADC data frame in the FIFO (see also chapter 5.1). By default the SADC is set to read out the temperature sensor out (SADC_CTRL: SADC_CHSEL=0 in chapter 4.9). For additional settings please check chapter 4.9. See also Figure 79. The SADC can achieve a better resolution of 10 bits by means of oversampling (see chapter 9.2).

Due to the required conversion time, ADC data are not available during a shape but they would be available during next shape (there is a delay of one shape for these data).

Figure 79 SADC Integration

9.1 SADC Functionality

Four main tasks are performed by the FSM to control the SADC:

- Enabling:
 - The SADC module is enabled through the CSCx register in any phase of the FSM state (see also 4.10)
- Initialization:
 - The host selects the channel in the channel register from SADC_CTRL control register (see also chapter 4.9)
- Triggering:
 - Each chirp-start during the active phase of shapes will trigger the SADC sampling/conversion
 - or by sending a SADC_START to SADC_CTRL register (see chapter 4.9)
- Results:
 - The conversion results are stored in the result register SADC_RESULTS register (see chapter 4.24) after the sampling and conversion is completed

9.2 SADC Conversion Formula

The SADC clock signal is running at 20 MHz and is derived from $f_{\text{ADC_CLK}} = f_{\text{SYS_CLK}} = 80 \text{ MHz}$. The SADC startup time is 101 clock cycles without startup-calibration and 422 clock cycles with startup-calibration. If temperature or power supply conditions did not change dramatically, the startup-calibration can be avoided during frames.

Figure 80 SADC startup timing

The conversion time $N_{\text{CONV_LEN}}$ for a single analog to digital conversion into the result register SADC_RESULT (see chapter 4.24) is defined by the following relation:

$$N_{\text{CONV_LEN}} = (N_{\text{conv}} + N_{\text{sample_dflt}} + \text{SESP} \times N_{\text{spread_early_sample}}) \times \text{OVS}$$

Where:

$N_{\text{conv}} = 13$ clock cycles

$N_{\text{sample_dflt}} = 16$ clock cycles

$N_{\text{spread_early_sample}} = 16$ clock cycles

OVS ... see SADC_CTRL: OVERS_CFG (see chapter 4.9)

SESP ... see SADC_CTRL: SESP (see chapter 4.9).

The SADC conversion formula for 8 bits resolution is:

$$D_{\text{out}_{8b}} = ((2^8 \times V_{\text{Ain}}) / V_{\text{REFP}}) \times G_{\text{Ain}} \text{ with an error of } \pm 0.1\%$$

Where:

V_{Ain} is the analog input to the SADC

G_{Ain} is the gain of the ADC module and can be set either to 1 or 0.75 (see chapter 4.9)

$V_{\text{REFP}} = 1.21 \text{ V}$.

In order to achieve 10 bits resolution, the oversampling should be set to 32 (see chapter 4.9).

In order to measure correctly the power sensor output, see chapters 7.1.2 and 4.9.

Note: Disabling the SADC

To disable the SADC simply set in register CSCx (see chapter 4.11) SADC_ISOPD = '0_B' ($f_{\text{SYS_CLK}}$ has to be still provided for at least one additional cycle for the command to take effect).

10 Enhanced Functions

10.1 Chip ID Readout

Readout sequence:

1. Enable the EFUSE block by setting DFT0: EFUSE_EN = 1 with a single dedicated SPI write, while keeping all other fields in DFT0 with default values.
2. Initiate the sense operation by setting DFT0: EFUSE_SENSE = 1 and keeping DFT0: EFUSE_EN enabled
3. Wait for 2us or poll the register field DFT1: EFUSE_READY = 1.
4. Read out the device ID from CHIP ID #1 and CHIP ID #2.
5. Disable the EFUSE block DFT0: EFUSE_EN = 0.

10.2 Data Test Mode

A linear feedback shift register (LFSR) is built-in on chip. It will generate a pseudo random bit M-sequence that can be used to fill up the FIFO. This can be used to develop and test the complete pipeline from the FIFO on the BGT60ATR24C up to the Application Processor (AP) memory, including firmware and drivers, with a defined bit sequence.

The implemented LFSR is described by the following polynomial: $x^{12} + x^{11} + x^{10} + x^4 + 1$.

Figure 81 Digital pipeline simplified block diagram

The first ADC channel ADC_CH1 output data stream is bypassed by the data sequence coming from the LFSR generator.

The other channels can be disabled or used in normal operation.

- This test mode can be started with bit SFCTL: LFSR_EN= 1_B (see also 4.8):
- Activate test data instead of ADC data

Enhanced Functions

- Initialization with MAIN: FSM_RESET= 1_B

10.3 CW Mode

In the continuous wave (CW) mode the device will be set to provide a constant output frequency. During CW mode no shapes are executed.

During the execution of this mode:

- Freq/timing parameters defined in shape registers are ignored
- PLL / RF / ADC runs with values programmed in PLL DFT0 (4.18) and CSU1 (4.10).
- All other CSx / shape settings are not handed over to functional blocks
- The values for REPS/REPC/REPT and frame relevant timings are used to shape a “virtual frame”
- Data from the FIFO can be read out following the structure of that “virtual frame”

Note:

For test purposes the “virtual frame” definition should be kept simple: 1 shape, 1 CS, e.g.

10.3.1 Enabling the CW mode

The CW mode should be preceded by either an HW or SW reset.

After this in order to enable the CW mode, the steps below should be followed:

- Enable the MAIN: CW_MODE= 1_B (see 4.2)
- Initialize the chip registers according to defined “virtual frame” (settings in 4.10 and 4.16)
- Enable the clock: PACR1: OSCCLKEN (see 4.6)
- Set frequency via PLLx: FSU setting from shape 1
- Set channel set for CSD/CSI/CSU1 (see 4.11)
- set PLL DFT0: BYPRMPEN= 1_B (see 4.18)

By using the FRAME_START as trigger, the chip can be set in the different states of a shape as shown in Figure 82:

- TRIG#1: jump to 1 (DS -> IDLE)
- TRIG#2: jump to 2 (IDLE -> INIT0)
- TRIG#3: jump to 3 (INIT0 -> INIT1)
- TRIG#4: jump to 4
- TRIG#5: jump to 6
- TRIG#6: jump to 7
- Frequency update: at this stage the output frequency can be updated/programed (FSU) to any value and the current frequency will be updated immediately after PLL transition of DFT0: BYPRMPEN= 0_B -> 1_B.
- TRIG7: jump to 8
- At this stage the APU number of samples is generated by the ADC according to the ADC0 settings. In case if APU=0 no triggers are generated, manual triggering of MADC can be done via ADC0: TRIG_MADC. Once the APU number of samples is generated another automatic generation of samples can be done after FSM reset.
- TRIG8: jump to 10
- TRIG9: jump to 11
- TRIGx

Figure 82 Steps that can be followed during a “virtual frame”

The FSM-reset will set back the FSM to initial state to start again with TRIG1.

This specific mode is intended also to test the power consumption of the chip during a specific sequence. It will offer the opportunity to break the expected shape that should be run during the radar (active) mode in static steps where the current consumption can be measured.

10.3.2 Baseband and ADC Test Mode

A test-tone generator can be used together with the CW mode. A test signal source derived from the OSC_CLK input at 80 MHz can be activated in the analog receiver chain; the same in each Rx chain. This test signal can be programmed in the register RFT0 (see chapter 4.19). The test tone can propagate through to each baseband chain by enabling a dedicated path. The MADC is triggered by the TRIG7 in Figure 82 and will sample the number of samples specified in the APU1 (see chapter 4.16). To run a new measurement an FSM-Reset is required.

Figure 83 Baseband/ADC test block diagram

This feature represents a very convenient way to test and debug a complete system. The customer can program a dedicated frequency, set the baseband gain and cutoff filter of the HPF (0), set the ADC (see 4.3), and readout via SPI the sampled data into the application processor or microcontroller unit to verify if the complete baseband chain is working as expected.

In Figure 84 is reported one example of ADC readout when the baseband is fed with a test tone at 400kHz internally derived from the OSC_CLK input. Different readouts from different VGA settings are reported.

Figure 84 Example: ADC readout after FFT

10.4 IRQ Output

BGT60ATR24C provides one interrupt pin output (IRQ). In default mode, the IRQ signal is used to monitor the filling level of the FIFO as described below.

IRQ status definition:

- IRQ is high after:
 - CS_N goes high and FSTAT: FILL_STATUS $\geq$ SFCTL: FIFO_CREF (see also 4.8 and 4.25).
- IRQ is low (as a consequence of):
 - CS_N goes high and FSTAT: FILL_STATUS $<$ SFCTL: FIFO_CREF (see also 4.8 and 4.25).
 - or CS_N is active low

The following figure shows the IRQ signal in case of FIFO-burst reads.

Figure 85 IRQ status behavior during radar mode with FSM capturing data

Package

11 Package

BGT60ATR24C is housed in the PG-VFWLB-76-1 eWLB package with solder balls of 350 µm diameter and a minimum standoff of 250 µm. According to IPC/JEDEC's J-STD, the moisture sensitivity level, MSL, is 3. The package size is (6.0 x 6.0 x 0.83) mm³ with a general solder ball pitch of 500 µm except for the RF solder balls which are off-grid to support a RF package-to-PCB transition.

12 Abbreviations

Table 69 **Abbreviations**

Symbol	Description
AAF	Anti-aliasing filter
ADC	Analog to digital converter
AP	Application Processor
DAC	Digital to analog converter
ES	Engineering samples
EES	Early engineering samples
ESD	Electrostatic discharge
FMCW	Frequency modulated continuous wave
HBM	Human body model (related to ESD)
CDM	Charge device model (related to ESD)
HPF	High pass filter
IC	Integrated circuit
LPF	Low pass filter
MCU	Microcontroller Unit
PLL	Phase locked loop integrated circuit
RF	Radio Frequency
RSVD	Reserved
RX	Receiver
SPI	Serial peripheral interface
TX	Transmitter
LDO	Low dropout voltage regulator
RST	Reset or Default setting
MSB	Most significant bit
LSB	Least significant bit
VGA	Variable gain amplifier

13 Revision History

Revision History: 2023-11-20, Revision 1.6	
Page	Description of change
1	Added ordering information and product picture on cover page
48	SADC_CLK_DIV divider values corrected in Table 28
88	Changed maximum PLL phase noise from -75 dBc/Hz to -70 dBc/Hz (Number 6.3.10 in Table 58)
92	SADC channel numbers for power detector corrected below Table 59
110	Added package footprint and tape figures in chapter 11
*	Fixed typos
