

# TLE92108-231QX

## Multiple MOSFET Driver IC

## 1 Overview

### Features

- Eight half-bridge gate drivers for external N-channel MOSFETs
- Control of reverse battery protection MOSFET
- Adaptive MOSFET gate control
  - Improved electromagnetic emission
  - Reduced switching losses in PWM mode
- 24-bit Serial Peripheral Interface
- Two current sense amplifiers with configurable gain
  - High-side and low-side capable for protection and diagnosis
- Drain-source monitoring for short circuit detection
- Overtemperature warning and shutdown
- Timeout watchdog
- Detailed off-state diagnostic (open load, short circuit to battery or short circuit to GND) via SPI
- Three PWM inputs
  - High-side and low-side PWM capable
  - Active free-wheeling
  - Up to 25 kHz PWM frequency
- Low current consumption in sleep mode
- Leadless power package with support of optical lead tip inspection
- Green Product (RoHS compliant)
- AEC Qualified

### Potential applications

- Seat control and extended functions (steering column adjustment, gas pedal adjustment)
- Central door lock
- Body control module (cargo cover, washer pump, window lift, rear wiper ...)

### Product validation

Qualified for automotive applications. Product validation according to AEC-Q100.

## Overview

## Description

The TLE92108-231QX is a Multi-MOSFET driver IC dedicated to control up to sixteen n-channel MOSFETs. It includes eight half-bridges for DC motor control applications such as automotive power seat control or other applications.

A 24-bit Serial Peripheral Interface (SPI) is used to configure the TLE92108-231QX and to control the half-bridges. It also allows the read out of the status registers for diagnostic purpose.

The TLE92108-231QX offers a wide range of diagnostic features such as the monitoring of the supply voltage, the charge pump voltage, temperature warning and over-temperature shutdown. Each gate driver monitors independently its external MOSFET drain-source voltage for fault conditions.

The device is housed in a VQFN-48 with exposed pad supporting lead tip inspection. The package provides a good thermal performance and minimizes the required PCB space.

Type	Package	Marking
TLE92108-231QX	PG-VQFN-48	TLE92108-231QX

## Block diagram

### 2.1 Voltage and current definition

**Figure 2** shows terms used in this datasheet, with associated convention for positive value.

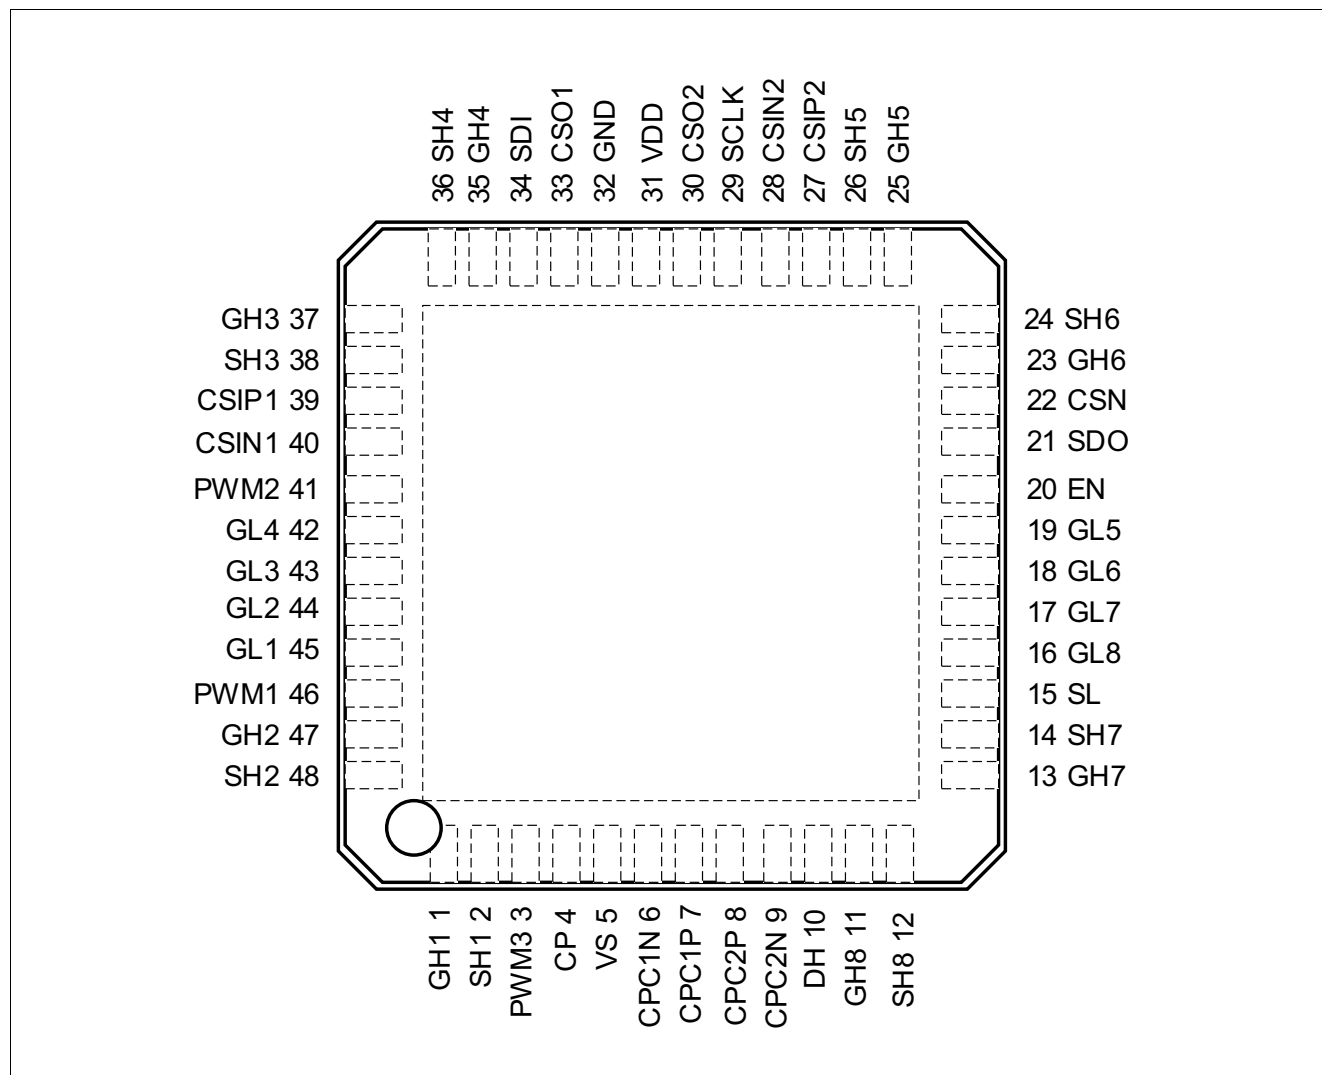

**Figure 2 Voltage and current definition**

## Pin configuration

### 3 Pin configuration

#### 3.1 Pin assignment

**Figure 3 Pin configuration TLE92108-231QX**

## Pin configuration

### 3.2 Pin definitions and functions

**Table 1** Pin configuration TLE92108-231QX

Pin	Symbol	Function
1	GH1	<b>Gate high-side 1</b> Analog I/O pin to turn on/off high-side MOSFET 1. Connect to the gate of high-side MOSFET 1.
2	SH1	<b>Source high-side 1</b> Connection to source of high-side MOSFET 1.
3	PWM3	<b>PWM input 3</b>
4	CP	<b>Charge Pump Output</b>
5	VS	<b>Supply Voltage</b> Device supply voltage. Connect this pin to the supply (battery) voltage with a reverse battery protection circuit.
6	CPC1N	<b>Negative connection to Charge Pump Capacitor 1</b>
7	CPC1P	<b>Positive connection to Charge Pump Capacitor 1</b>
8	CPC2P	<b>Positive connection to Charge Pump Capacitor 2</b>
9	CPC2N	<b>Negative connection to Charge Pump Capacitor 2</b>
10	DH	<b>Drain input for high-sides</b> Input for the drains of high-side MOSFETs. Refer to <a href="#">Chapter 7.3</a> .
11	GH8	<b>Gate high-side 8</b>
12	SH8	<b>Source high-side 8</b>
13	GH7	<b>Gate high-side 7</b>
14	SH7	<b>Source high-side 7</b>
15	SL	<b>Source low-side</b> Common connection to the source of the low-side MOSFETs.
16	GL8	<b>Gate low-side 8</b>
17	GL7	<b>Gate low-side 7</b>
18	GL6	<b>Gate low-side 6</b>
19	GL5	<b>Gate low-side 5</b>
20	EN	<b>Enable input</b> with internal pull-down
21	SDO	<b>Serial Data Output</b>
22	CSN	<b>Chip Select Not</b> with internal pull-up
23	GH6	<b>Gate high-side 6</b>
24	SH6	<b>Source high-side 6</b>
25	GH5	<b>Gate high-side 5</b>
26	SH5	<b>Source high-side 5</b>
27	CSIP2	<b>Non-Inverting input of the Current Sense Amplifier 2</b>
28	CSIN2	<b>Inverting input of the Current Sense Amplifier 2</b>
29	SCLK	<b>Serial Clock Input</b> with internal pull-down
30	CSO2	<b>Current Sense Amplifier Output 2</b>

## Pin configuration

**Table 1 Pin configuration TLE92108-231QX**

Pin	Symbol	Function
31	VDD	<b>Logic supply</b>
32	GND	<b>Ground connection</b>
33	CSO1	<b>Current Sense Amplifier Output1</b>
34	SDI	<b>Serial Data Input</b> with internal pull-down
35	GH4	<b>Gate high-side 4</b>
36	SH4	<b>Source high-side 4</b>
37	GH3	<b>Gate high-side 3</b>
38	SH3	<b>Source high-side 3</b>
39	CSIP1	<b>Non-inverting input of the Current Sense Amplifier 1</b>
40	CSIN1	<b>Inverting input of the Current Sense Amplifier 1</b> . This pin can be used as reference for the high-side MOSFET drain if CSA1 is configured as high-side. Refer to <a href="#">Chapter 7.3</a>
41	PWM2	<b>PWM input 2</b>
42	GL4	<b>Gate low-side 4</b>
43	GL3	<b>Gate low-side 3</b>
44	GL2	<b>Gate low-side 2</b>
45	GL1	<b>Gate low-side 1</b>
46	PWM1	<b>PWM input 1</b>
47	GH2	<b>Gate high-side 2</b>
48	SH2	<b>Source high-side 2</b>
	E.P.	<b>Exposed pad</b> For cooling purpose only, do not use as electrical GND <sup>1)</sup> .

- 1) The exposed pad at the bottom of the package allows better power dissipation from TLE92108-231QX via the PCB. The exposed pad must be left floating or connected to GND (recommended) for best EMC and thermal performance.

## 4 General product characteristics

### 4.1 Absolute maximum ratings

**Table 2 Absolute maximum ratings<sup>1)</sup>**

$T_j = -40^{\circ}\text{C}$  to  $150^{\circ}\text{C}$ ; all voltages with respect to ground, positive current flowing into pin  
(unless otherwise specified)

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Voltages							
Supply voltage	$V_S$	-0.3	–	40	V	–	P_4.1.1
PWM input voltages (PWMx)	$V_{\text{PWMx}}$	-0.3	–	$V_{\text{DD}} + 0.3$	V	$ I  < 10 \text{ mA}$	P_4.1.2
Logic input voltages (SDI, SCLK, CSN, EN)	$V_{\text{SDI}}, V_{\text{SCLK}}, V_{\text{CSN}}, V_{\text{EN}}$	-0.3	–	$V_{\text{DD}} + 0.3$	V	$ I  < 10 \text{ mA}$	P_4.1.3
Voltage range and SDO	$V_{\text{SDO}}$	-0.3	–	$V_{\text{DD}} + 0.3$	V	$ I  < 10 \text{ mA}$	P_4.1.4
Voltage range at CSIPx and CSINx	$V_{\text{CSIP}}, V_{\text{CSIN}}$	-8.0	–	40	V	–	P_4.1.5
Differential input voltage range CSIPx - CSINx	$V_{\text{CSIDiff}}$	-8.0	–	8.0	V	–	P_4.1.21
Voltage range at DH	$V_{\text{DH}}$	-0.3	–	40	V	–	P_4.1.6
Voltage range at SL	$V_{\text{SL}}$	-8.0	–	6.0	V	–	P_4.1.7
Voltage range at SHx	$V_{\text{SH}}$	-8.0	–	48	V	–	P_4.1.8
Voltage range at GHx	$V_{\text{GH}}$	-8.0	–	48	V	–	P_4.1.9
Voltage range at GLx	$V_{\text{GL}}$	-8.0	–	24	V	–	P_4.1.10
Voltage difference between GLx and SL	$V_{\text{GS\_LS}}$	-0.3	–	16	V	–	P_4.1.11
Voltage difference between GHx and SHx	$V_{\text{GS\_HS}}$	-1.0	–	16	V	2)	P_4.1.23
Voltage range at charge pump pins CP	$V_{\text{CP}}$	$V_S - 0.3$	–	$V_S + 15$	V	–	P_4.1.12
Voltage range at charge pump pins CPC1N, CPC1P, CPC2N, CPC2P	$V_{\text{CPCx}}$	$V_{\text{CP}} - 0.3$	–	$V_{\text{CP}} + 0.3$	V	–	P_4.1.22
Logic supply voltage	$V_{\text{DD}}$	-0.3	–	5.5	V	–	P_4.1.13
Voltage at CSOx	$V_{\text{CSOx}}$	-0.3	–	$V_{\text{DD}} + 0.3$	V	–	P_4.1.14

### Temperatures

Junction temperature	$T_j$	-40	–	150	$^{\circ}\text{C}$	–	
Storage temperature	$T_{\text{stg}}$	-55	–	150	$^{\circ}\text{C}$	–	P_4.1.16

**General product characteristics**

**Table 2 Absolute maximum ratings<sup>1)</sup>** (cont'd)

$T_j = -40^{\circ}\text{C}$  to  $150^{\circ}\text{C}$ ; all voltages with respect to ground, positive current flowing into pin  
(unless otherwise specified)

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
ESD susceptibility							
ESD susceptibility all pins	$V_{\text{ESDHBM1}}$	-2	–	2	kV	HBM <sup>3)</sup>	P_4.1.17
ESD susceptibility of VS and DH pins versus GND	$V_{\text{ESDHBM2}}$	-4	–	4	kV	HBM <sup>3)</sup>	P_4.1.18
ESD susceptibility all pins	$V_{\text{ESDCDM1}}$	-500	–	500	V	CDM <sup>4)</sup>	P_4.1.19
ESD susceptibility pin corner pins	$V_{\text{ESDCDM2}}$	-750	–	750	V	CDM <sup>4)</sup>	P_4.1.20

1) Not subject to production test, specified by design.

2)  $V_{\text{GS\_GH}}$  may be between -1.0 and -0.3V only if the current injected into SHx is below 4 mA

3) ESD susceptibility, HBM according to ANSI/ESDA/JEDEC JS001 (1.5 kΩ, 100 pF).

4) ESD susceptibility, Charged Device Model “CDM” according JEDEC JESD22-C101.

**Notes**

1. Stresses above the ones listed here may cause permanent damage to the device. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.
2. Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as “outside” normal operating range. Protection functions are not designed for continuous repetitive operation.

**4.2 Functional range**

**Table 3 Functional range**

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Supply voltage range for normal operation	$V_{\text{S(nor)}}$	6.0	–	28	V	–	P_4.2.1
Extended supply voltage range	$V_{\text{S(ext)}}$	5.5	–	6	V	<sup>1)</sup> Parameter deviations possible	P_4.2.7
Extended supply voltage range	$V_{\text{S(ext)}}$	28	–	$V_{\text{SOV\_OFF2 (max)}}$	V	<sup>1)</sup> Parameter deviations possible	P_4.2.2
Supply voltage transients slew rate	$dV_{\text{S}}/dt$	-10	–	10	V/μs	<sup>1)</sup>	P_4.2.3
Logic supply voltage	$V_{\text{DD}}$	3.0	–	5.5	V	–	P_4.2.4
SPI logic input voltage	$V_{\text{SDI}},$ $V_{\text{SCLK}},$ $V_{\text{CSN}}$	0	–	$V_{\text{DD}}$	V	–	P_4.2.5
Junction temperature	$T_j$	-40	–	150	°C	–	P_4.2.6

**General product characteristics**

1) Not subject to production test, specified by design.

*Note: Within the functional or operating range, the IC operates as described in the circuit description. The electrical characteristics are specified within the conditions given in the Electrical Characteristics table.*

**General product characteristics**

**4.3 Thermal resistance**

*Note:* This thermal data was generated in accordance with JEDEC JESD51 standards. For more information, go to [www.jedec.org](http://www.jedec.org).

**Table 4 Thermal resistance**

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Junction to case	$R_{thJC}$	–	4.4	–	K/W	1)	
Junction to ambient	$R_{thJA}$	–	27	–	K/W	1)2)	

1) Not subject to production test, specified by design.

2) Specified  $R_{thJA}$  value is according to Jedec JESD51-2,-5,-7 at natural convection on FR4 2s2p board; The Product (Chip+Package) was simulated on a 76.2 × 114.3 × 1.5 mm board with 2 inner copper layers (2 × 70 mm Cu, 2 × 35 mm Cu). Where applicable a thermal via array under the exposed pad contacted the first inner copper layer.

## General description

## 5 General description

### 5.1 Power supply

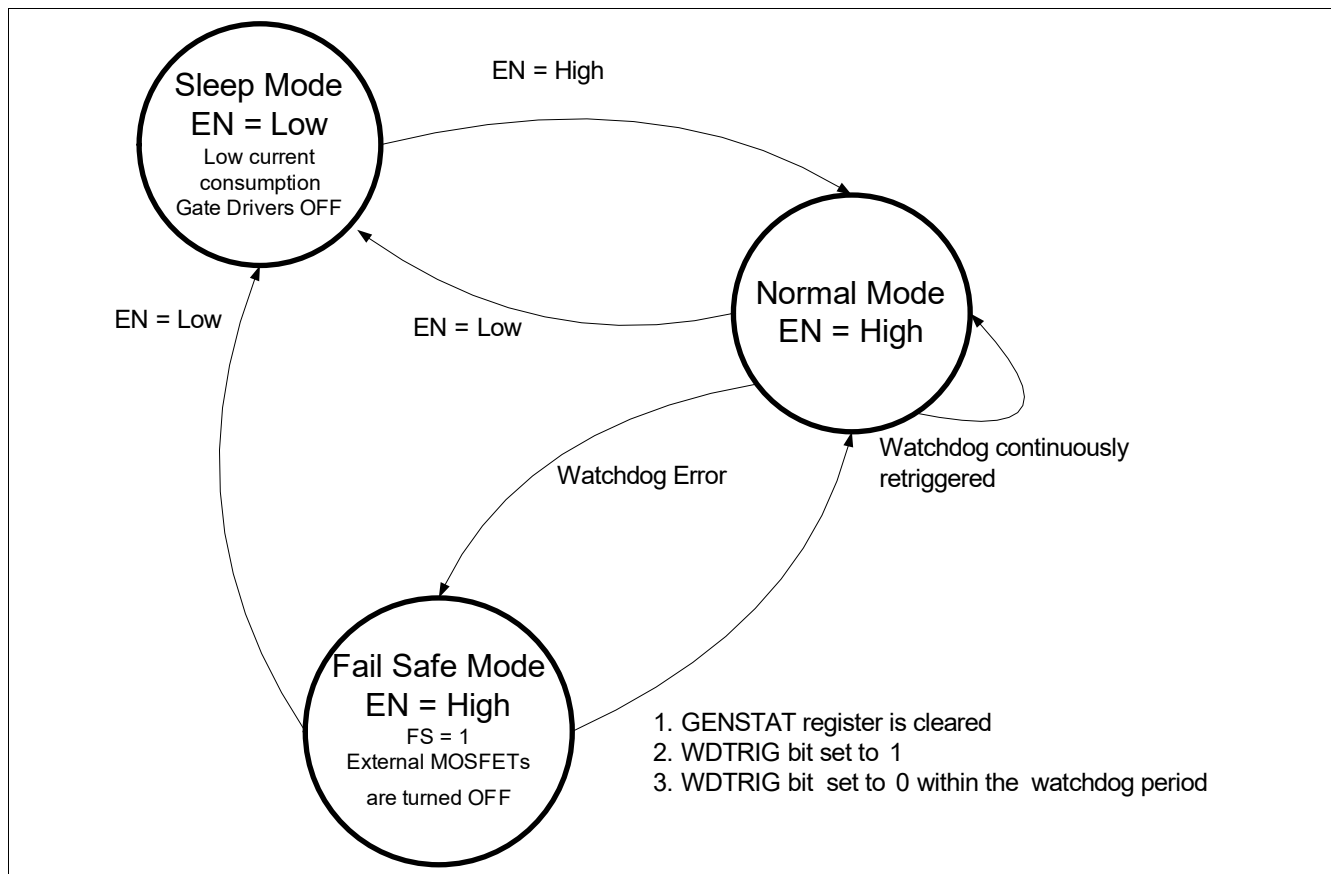

The Multiple MOSFET Driver IC requires two power supplies:  $V_S$  and  $V_{DD}$ .

$V_{DD}$  supplies the I/O buffers (including the SPI pins) and the internal voltage regulator for the logic.  $V_{DD}$  allows the flexibility of a 3.3 V or a 5.0 V logic interface.

$V_S$  supplies the charge pump for the MOSFET gate drivers. The  $V_S$  pin must be connected to the battery through a reverse battery protection.

Both supplies are separated so that the information stored in the logic remains intact in the event of voltage drop on  $V_S$ .  $V_{DD}$  and  $V_S$  should be decoupled with ceramic capacitors connected close to the supply and ground planes.

### 5.2 Operation modes

**Figure 4 State diagram**

*Note:* The state diagram is valid for  $V_S$  and  $V_{DD}$  within the nominal operating range. For  $V_S$  and  $V_{DD}$  outside of the nominal range, refer to [Chapter 7.7](#), respectively [Chapter 5.2.2](#).

#### 5.2.1 Normal mode

The TLE92108-231QX enters Normal Mode by setting EN pin to High and waiting for the SPI setup time  $t_{SET\_SPI}$ . In normal mode, the MOSFET gate drivers are enabled and can be configured through the SPI interface,

## General description

provided that the voltages applied to  $V_{DD}$  and  $V_S$  are within the operating range. The watchdog must be retriggered correctly in order to stay in Normal Mode (see [Chapter 7.9](#)).

### 5.2.2 Sleep mode

The Multiple MOSFET Driver IC enters Sleep Mode by setting EN pin to Low. The transition to the sleep mode is delayed by  $t_{DSLEEP}$ <sup>1)</sup> (max  $t_{CCP}$  of active half-bridges + 3  $\mu$ s) in order to actively turn-off the external MOSFETs. In this mode, the internal regulator and the internal circuitry are deactivated, and the SPI registers are reset.

The current consumption of  $V_{DD}$  is reduced to  $I_{DD\_Q}$ . The current consumption of  $V_S$  is reduced to  $I_{SQ}$  or  $I_{SQ} + I_{SQ\_BRAKE}$ .

The  $V_S$  current consumption is  $I_{SQ}$  if  $V_S$  never drops below  $V_{SLEEP\_SET}$  after entering sleep mode.

The  $V_S$  current consumption is  $I_{SQ} + I_{SQ\_BRAKE}$  if  $V_S$  has recovered from a voltage below  $V_{SLEEP\_SET}$  (i.e.  $V_S$  has ramped up from a voltage below  $V_{SLEEP\_SET}$  or  $V_S$  has dropped below  $V_{SLEEP\_SET}$ )

The internal resistors  $R_{GGND}$  between GHx/GLx and GND are activated to discharge the gate of the external MOSFETs.

*Note: If EN is set to Low for a duration shorter than ( $t_{ENL\_FLT}$ , 8  $\mu$ s max.), and EN is set to High again, then device does not go in sleep mode and the registers are not reset. The half-bridges are reactivated according to the settings of the control registers when EN is High.*

### 5.2.3 Fail Safe Mode

In case of watchdog error (see [Chapter 7.9](#)), the device enters Fail Safe Mode, FS bit is set (see [Global status byte](#)) and the external MOSFETs are actively discharged with the static discharge current ([Chapter 6.2](#)) during the max. configured  $t_{HBxCCP}$  active ([Chapter 7.4.1](#)). Then the bridge driver is set to passive mode (the passive discharge path is activated, [Chapter 6.4](#), all external MOSFETs are latched off, and the charge pump is deactivated). To resume Normal Mode the microcontroller must execute the following sequence<sup>2)</sup>:

1. Clear **GENSTAT** register.
2. Write WDTRIG bit to 1 (**GENCTRL1**) within the watchdog period.
3. Write WDTRIG bit to 0 within the watchdog period<sup>3)</sup>.

In fail safe mode, the control registers are frozen to their default value, at the exception of **WDTRIG**, **CCSO**, **CSA1L**, **CSA2L**. Any write command (except for WDTRIG bit) or clear command (except for GENSTAT) will be discarded in this mode and sets SPIE bit ([Global status byte](#)).

A clear command to **GENSTAT** in fail safe mode does not reset any failure flag reported by this status register. The control and status registers can be read in this mode before the start of the exit sequence without SPIE bit being set.

1) SPI Frames are ignored during  $t_{DSLEEP}$ .

2) The exit sequence must be strictly followed to leave fail safe mode. If a SPI frame not belonging to the sequence is added, then the device stays in fail safe mode and the microcontroller must restart the complete sequence to enter normal mode.

3) During Fail Safe Mode, the charge pump is deactivated and **CPUV** is set. Therefore, recovering from Fail Safe Mode, **GENSTAT** must be cleared again at the end of the Fail Safe exit sequence to re-activate of the gate drivers.

## General description

### 5.3 Reset behavior

The following events trigger a Power On Reset:

#### **$V_{DD}$ undervoltage reset:**

If  $V_{DD} < V_{DD\ PoffR}$  the digital block is deactivated and the outputs are switched off. The digital block is reset once  $V_{DD} > V_{DD\ POR}$ . Then NPOR bit (negated power-on reset bit, see [Global status byte](#)) is reset to 0 to report the reset condition.

#### **Reset on EN pin:**

If the EN pin is pulled low, the logic content is reset and the device enters sleep mode. Once the device enters Normal Mode (after  $t_{SET\_SPI}$  with EN = high and  $V_{DD} > V_{DD\ POR}$ ), the NPOR bit is reset to 0 to report the reset condition.

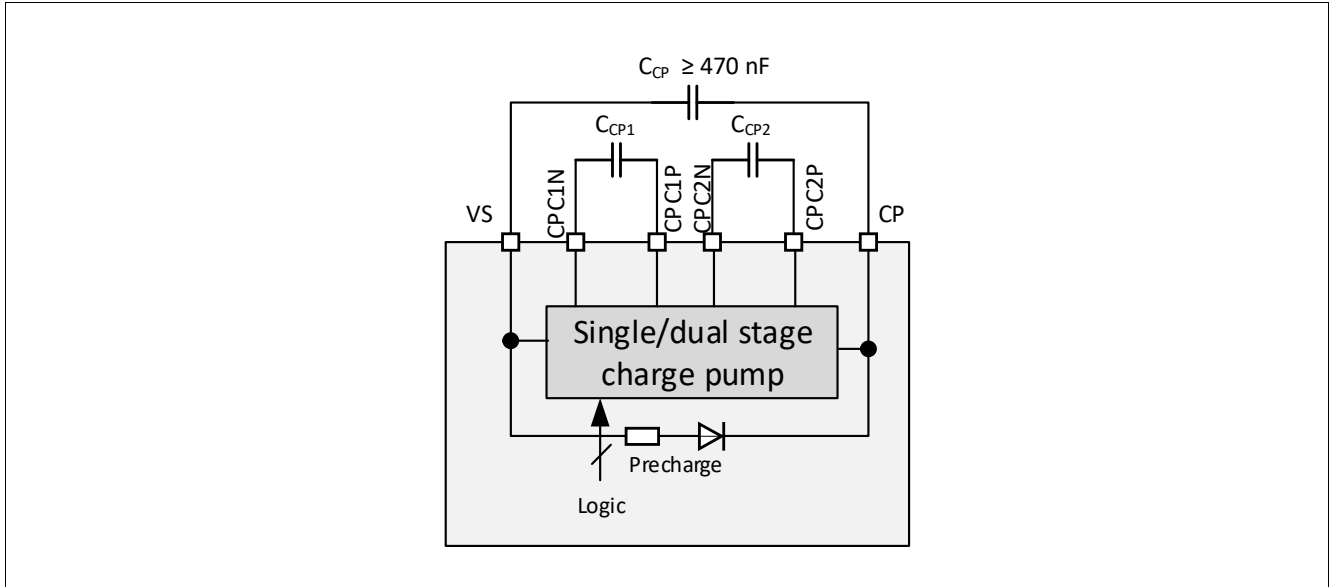

NPOR is set to 1 when [GENSTAT](#) is cleared.

## General description

### 5.4 Charge pump

A dual-stage charge pump supplies the gate drivers for the high-side and low-side MOSFETs. It requires three external capacitors connected between CPC1N and CPC1P, CPC2N and CPC2P, VS and CP.

**Figure 5** Charge pump

CPSTGA = 0 (default, see [GENCTRL2](#)), the device operates with the dual-stage charge pump.

If CPSTGA = 1 ([GENCTRL2](#)), the device switches automatically to single-stage or dual-stage charge pump automatically:

- If  $V_S > V_{CPSO\ DS}$ : the TLE92108-231QX switches from a dual-stage to a single-stage charge pump.
- If  $V_S < V_{CPSO\ SD}$ : the TLE92108-231QX switches from single-stage to dual-stage charge pump.

The operation with the single-stage charge pump reduces the current consumption from the VS pin.

### 5.5 Frequency modulation

A modulation of the charge pump frequency can be activated to reduce the peak emission. The modulation frequency can be selected based on the resolution bandwidth of the peak detector during EMC testing.

The modulation frequency is set by the control bit FMODE in [GENCTRL1](#)

- FMODE = 0: No modulation.
- FMODE = 1: Modulation frequency = 15.6 kHz (default).

## General description

### 5.6 Electrical characteristics

#### 5.6.1 Electrical characteristics: supply

**Table 5** Electrical characteristics: supply

$V_S = 6.0\text{ V}$  to  $18\text{ V}$  if  $V_{SOVTH} = 0$ ,  $V_S = 6.0\text{ V}$  to  $28\text{ V}$  if  $V_{SOVTH} = 1$ ;  $V_{DD} = 3.0\text{ V}$  to  $5.5\text{ V}$ ,  $T_j = -40^\circ\text{C}$  to  $150^\circ\text{C}$ , all voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

Parameter	Symbol	Values			Unit	Note or Test Condition	Number
		Min.	Typ.	Max.			
Current consumption, EN = LOW)							
Supply quiescent current	$I_{SQ}$	–	2	5	μA	$T_j < 85^{\circ}\text{C}$ , $V_S = 13.5\text{ V}$	P_5.5.1
Supply quiescent current	$I_{SQ2}$	–	5	7	μA	$T_j < 85^{\circ}\text{C}$ , $V_S < 25\text{ V}$	P_5.5.61
Additional supply quiescent current, brake enabled	$I_{SQ\_BRAKE}$	–	5	7.5	μA	$T_j < 85^{\circ}\text{C}$ , $V_S = 13.5\text{ V}^{1)}$	P_5.5.60
Logic Supply quiescent current	$I_{DD\_Q}$	–	1	3	μA	$T_j < 85^{\circ}\text{C}$	P_5.5.3

## Floating gate drivers

### 6 Floating gate drivers

The TLE92108-231QX integrates sixteen floating gate drivers capable of controlling a wide range of n-channel MOSFETs. They are configured as eight high-sides and low-sides, building eight half-bridges.

This section describes the MOSFET control by the gate drivers.

After power-on reset, the bridge driver is in passive mode (default value of **BD\_PASS** = 1 and all HBxMODE=00<sub>B</sub>). Refer to [Chapter 6.4](#) and [Chapter 6.5](#).

The bridge driver is in active mode by setting **BD\_PASS** to 0. [Chapter 6.1](#), [Chapter 6.2](#) and [Chapter 6.3](#) describes the static and PWM control in active mode.

**Attention:** *It is highly recommended to have all HBxMODE bits set to 00<sub>B</sub> or 11<sub>B</sub> before setting **BD\_PASS** to 0 in order to avoid wrong drain-source overvoltage detection.*

**Table 8**      **Operating modes of the gate driver**

EN	<b>BD_PASS</b>	HBxMODE[1:0]	Gate driver	Comment	Chapter
High	0	x	Active <sup>1)</sup>		<a href="#">Chapter 6.1</a> <a href="#">Chapter 6.2</a> <a href="#">Chapter 6.3</a>
High	1	One HBxMODE = 01 <sub>B</sub> or 10 <sub>B</sub>	Active <sup>1)</sup>	Equivalent to EN=High and <b>BD_PASS</b> = 0	<a href="#">Chapter 6.1</a> <a href="#">Chapter 6.2</a> <a href="#">Chapter 6.3</a>
High	1	All HBxMODE=00 <sub>B</sub> or 11 <sub>B</sub>	Passive		<a href="#">Chapter 6.5</a>
Low	x	x	Passive		<a href="#">Chapter 6.5</a>

1) Provided that no VS overvoltage, VS undervoltage, CP undervoltage or overtemperature failure are detected, and TLE92108-231QX is not in Fail Safe Mode.

Floating gate drivers

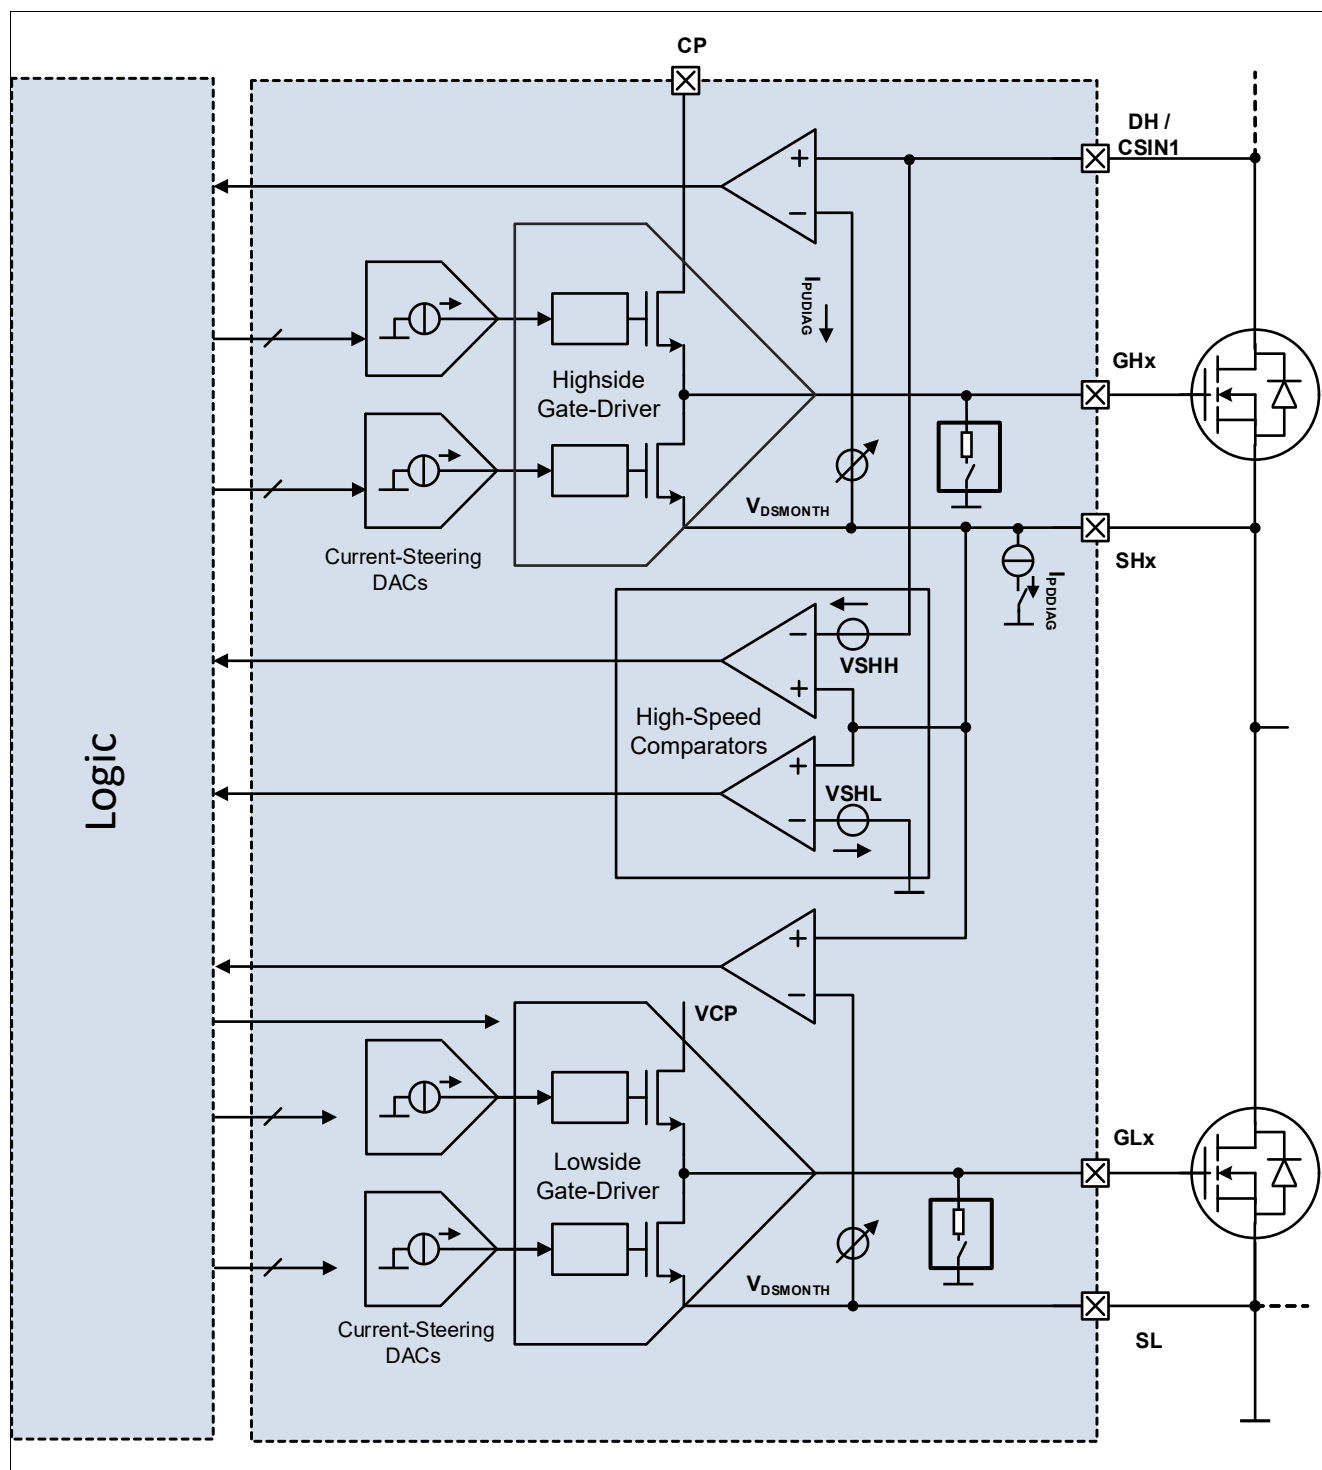

Figure 6 Block diagram - Gate driver for one half-bridge

## Floating gate drivers

### 6.1 MOSFET control with bridge driver in active mode (**BD\_PASS** = 0 and **EN** = High)

Depending on the configuration bits HBxMODE[1:0] (**HBMODE**, [Table 9](#) and [Table 11](#)), each high-side and low-side MOSFETs can be:

- deactivated
- activated (statically, no PWM)
- activated in PWM mode ([Chapter 6.3, PWMSET](#))

**Table 9 Half-bridge mode selection**

HBxMODE[1:0] <sup>1)</sup>	Configuration of HSx/LSx <sup>1)</sup>
00 <sub>B</sub>	LSx and HSx MOSFETs are actively kept OFF (default)
01 <sub>B</sub>	LSx MOSFET is ON (static or PWM, refer to <a href="#">Table 11</a> ), HSx MOSFET is actively kept OFF
10 <sub>B</sub>	HSx MOSFET is ON (static or PWM, refer to <a href="#">Table 11</a> ), LSx MOSFET is actively kept OFF
11 <sub>B</sub>	Reserved - LSx and HSx MOSFETs are actively kept OFF

1) x = 1 ... 8.

### 6.2 Static activation with bridge driver in active mode (**BD\_PASS** = 0)

In this section, we consider the static activation of the high-side and low-side MOSFET of the half-bridge x, x = 1...8. Refer to [Table 11](#) for the setting of a high-side or low-side in the static or PWM operation.

If HBx is not mapped to any activated PWM channel, the low-side or high-side MOSFET of HBx is statically activated (no PWM) by setting HBxMODE[1:0] to respectively (0,1) or (1,0).

The configured cross-current protection and the Drain-Source overvoltage blank times for the Half-Bridge x are noted  $t_{HBxCCP\ Active}$  and  $t_{HBxBLANK\ Active}$  (refer to [Chapter 7.4](#)).

The charge and discharge currents applied to the static controlled Half-Bridge x are noted ICHGSTx ([ST\\_ICHG](#)).

IHARDOFF is the maximum current that the gate drivers can sink. It corresponds to the discharge current when IDCHGx[4:0] = 31<sub>D</sub> (See [PWM\\_IDCHG\\_ACT](#)). This current is used to keep a MOSFET off, when the opposite MOSFET of the same half-bridge is being turned on. This feature avoids parasitic cross-current conduction.

ICHGSTx is the current sourced, respectively sunk, by the gate driver to turn-on the high-side x or low-side x. ICHGSTx is configured in the control register [ST\\_ICHG](#).

**Table 10 Static charge and discharge currents**

ICHGSTx[3:0] <sup>1)</sup>	Nom. charge current [mA] <sup>2)</sup>	Nom. discharge current [mA] <sup>3)</sup>	Max. deviation to typ. values
0000 <sub>B</sub>	1.0	1.0	+/- 60%
0001 <sub>B</sub>	2.0	2.8	+/- 60 %
0010 <sub>B</sub>	4.5	5.7	+/- 60 %
0011 <sub>B</sub>	8.0	9.4	+/- 38 %
0100 <sub>B</sub>	12.5	14.2	+/- 38 %
0101 <sub>B</sub>	17.8	19.7	+/- 38 %

## Floating gate drivers

**Table 10 Static charge and discharge currents**

ICHGSTx[3:0] <sup>1)</sup>	Nom. charge current [mA] <sup>2)</sup>	Nom. discharge current [mA] <sup>3)</sup>	Max. deviation to typ. values
0110 <sub>B</sub>	23.9	26.0	+/- 38 %
0111 <sub>B</sub>	30.0	32.0	+/- 28 %
1000 <sub>B</sub>	37.1	39.5	+/- 28 %
1001 <sub>B</sub>	44.3	46.8	+/- 28 %
1010 <sub>B</sub>	52.3	54.7	+/- 28 %
1011 <sub>B</sub>	60.2	62.5	+/- 28 %
1100 <sub>B</sub>	68.3	70.6	+/- 28 %
1101 <sub>B</sub>	76.8	78.5	+/- 28 %
1110 <sub>B</sub>	86.0	87.0	+/- 28 %
1111 <sub>B</sub>	96.0	95.0	+/- 25 %

1) Refer to **ST\_ICHG**

2)  $V_S \geq 8V$  and  $V_{GS} \leq V_{GS(ON)1}$  if ICHGSTx  $\leq 7_D$ ,  $V_S \geq 8V$  and  $V_{GS} \leq V_{GS(ON)2}$  if ICHGSTx  $\geq 8_D$

3)  $V_{GS} \geq V_{GS(OFF)1}$  if ICHGSTx  $\leq 7_D$ ,  $V_{GS} \geq V_{GS(OFF)2}$  if ICHGSTx  $\geq 8_D$

IHOLD is the hold current used to keep the gate of the external MOSFETs in the desired state. This parameter is configurable with the **IHOLD** control bit in **GENCTRL2**.

If **IHOLD** = 0:

- the MOSFETs are kept ON with the current  $I_{CHG8}$  (12.5 mA typ.)
- the MOSFETs are kept OFF with the current  $I_{DCHG8}$  (14.2 mA typ.)

If **IHOLD** = 1:

- the MOSFETs are kept ON with the current  $I_{CHG12}$  (23.9 mA typ.)
- the MOSFETs are kept with the current  $I_{DCHG12}$  (26.0 mA typ.)

**The static discharge current is applied to turn off the MOSFETs when the bridge driver is in active mode when the following failures occur:**

- $V_S$  undervoltage/overvoltage
- Overtemperature
- $V_{DS}$  overvoltage
- Charge pump undervoltage
- Overcurrent if OCEN = 1

### 6.2.1 Static activation of a high-side MOSFET

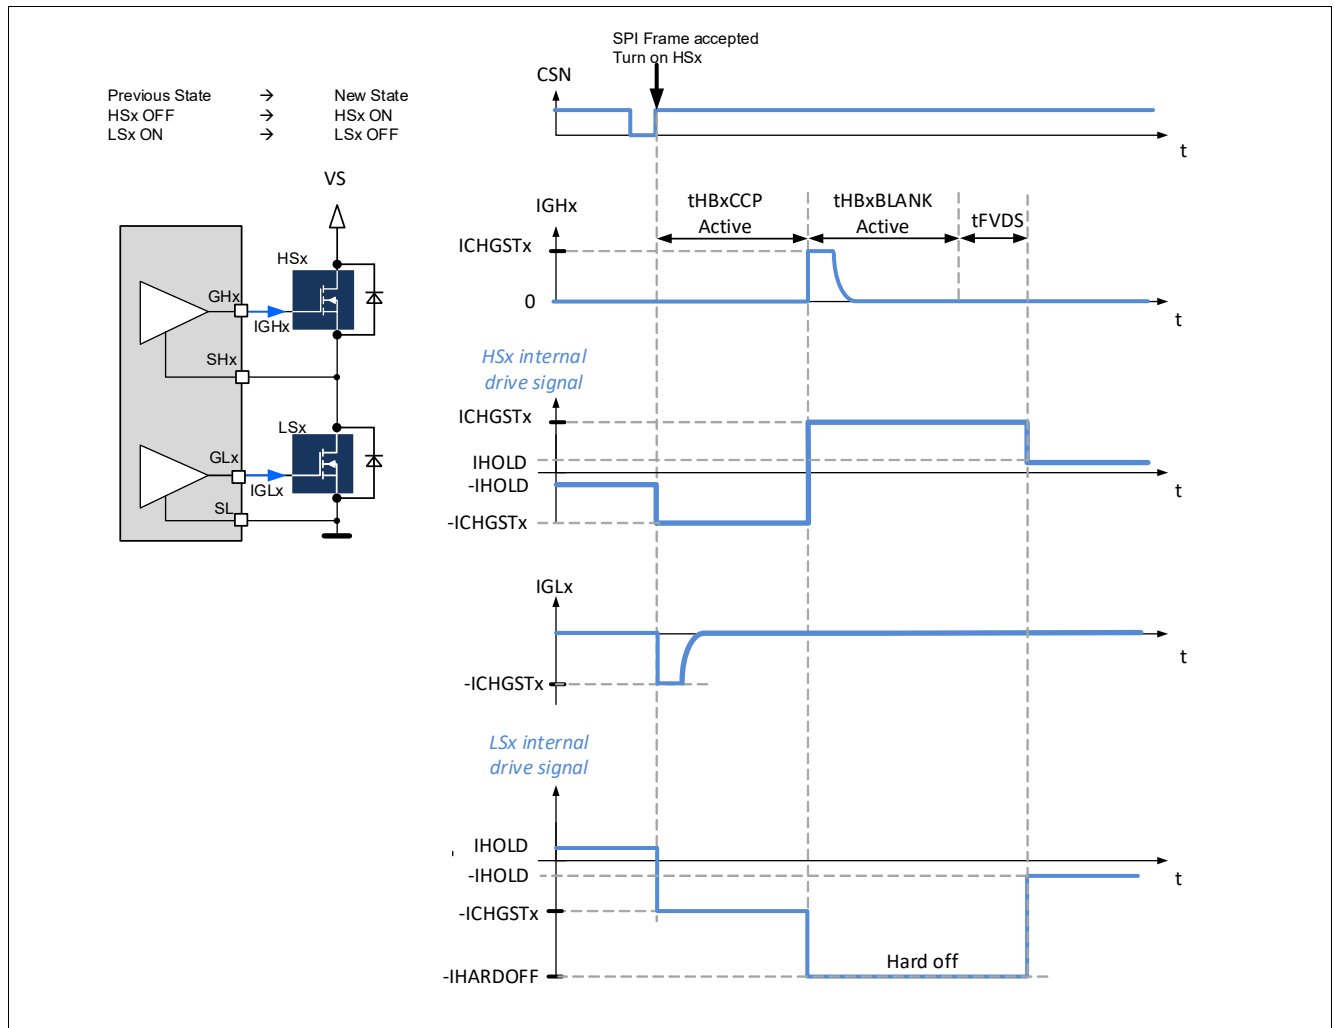

#### Turn-on with cross-current protection

If LSx is ON (HBxMODE[1:0] = 01<sub>B</sub>), before the activation of HSx (HBxMODE[1:0] = 10<sub>B</sub>) then the high-side MOSFET is turned on after a cross-current protection time (refer to **Figure 7**):

- after the CSN rising edge and for the duration  $t_{HBxCCP Active}$ :
  - the high-side MOSFET is kept OFF with the current -ICHGSTx
  - the gate of the low-side MOSFET is discharged with the current -ICHGSTx

## Floating gate drivers

- at the end of  $t_{HBxCCP \text{ Active}}$  and for the duration  $t_{HBxBLANK \text{ Active}} + t_{FVDS}$ :
  - the gate of the high-side MOSFET is charged with the current  $ICHGSTx$
  - low-side MOSFET is kept OFF with the current  $-IHARDOFF$  (hard off phase)
- at the end of  $t_{FVDS}$ :
  - the drive current of the high-side MOSFET is reduced to  $IHOLD$
  - the drive current of the low-side MOSFET is set to  $-IHOLD$

**Figure 7 Turn-on of a high-side MOSFET with cross-current protection**

**Note:** The CSN rising edge must be synchronized with the device logic. Therefore SPI commands are executed with a delay of up to 3  $\mu$ s after the CSN rising edge.

## Floating gate drivers

### Turn-on without cross-current protection

If LSx is OFF ( $\text{HBxMODE}[1:0] = 00_{\text{B}}$ ), before the activation of HSx ( $\text{HBxMODE}[1:0] = 10_{\text{B}}$ ), then the high-side MOSFET is turned on without cross-current protection (refer to **Figure 8**):

- after the CSN rising edge and for a duration  $t_{\text{HBxBLANK Active}} + t_{\text{FVDS}}$ :
  - the gate of the high-side MOSFET is charged with the current  $\text{ICHGSTx}$
  - the low-side MOSFET is kept OFF with the current  $-\text{IHARDOFF}$
- at the end of  $t_{\text{FVDS}}$ :
  - the drive current of the high-side MOSFET is reduced to  $\text{IHOLD}$
  - the drive current of the low-side MOSFET is set to  $-\text{IHOLD}$

**Figure 8** Turn-on of a high-side MOSFET without cross-current protection

**Note:** The CSN rising edge must be synchronized with the device logic. Therefore SPI commands are executed with a delay of up to  $3 \mu\text{s}$  after the CSN rising edge.

## Floating gate drivers

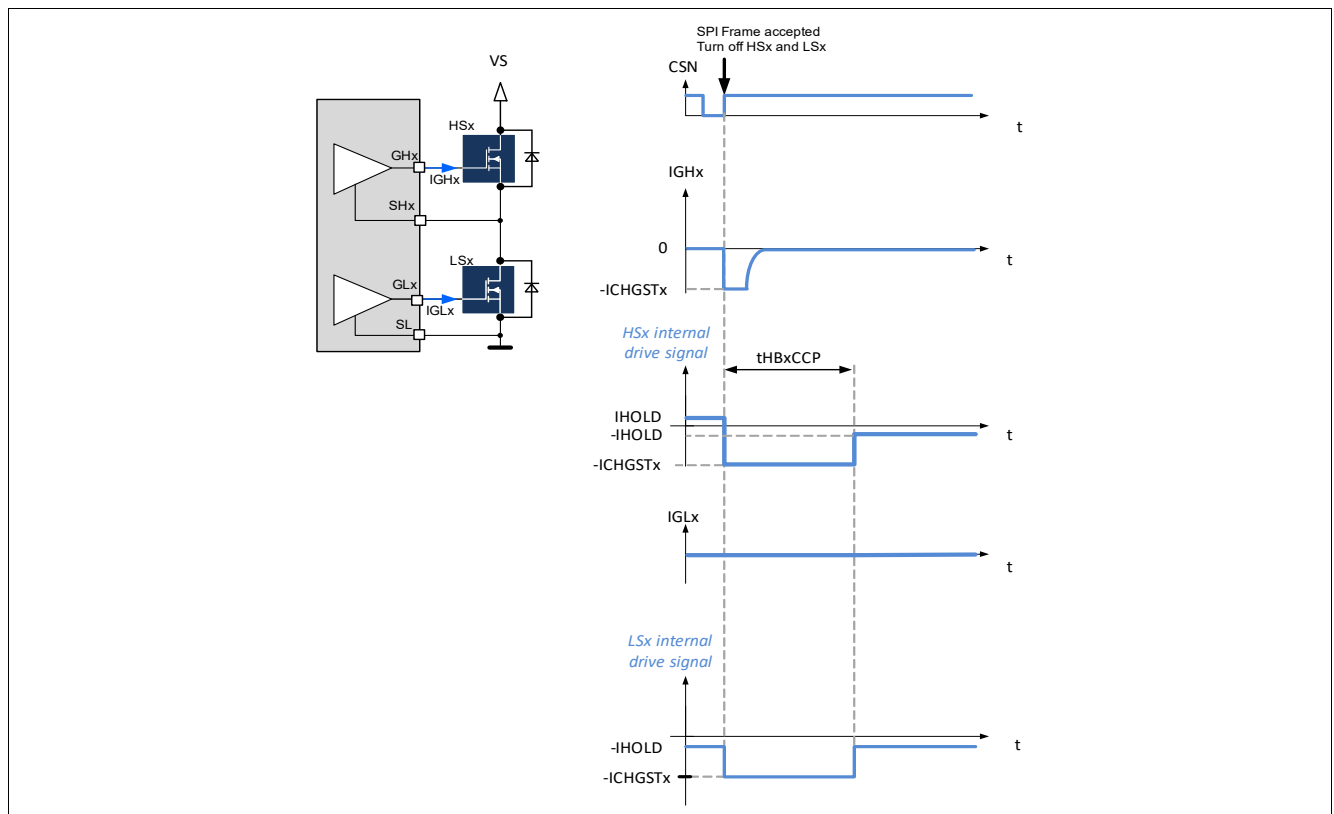

### 6.2.2 Static activation of a low-side MOSFET

The description of the static activation of a low-side x differs from the description of [Chapter 6.2.1](#) only by exchanging high-side x and low-side x.

### 6.2.3 Turn-off of the high-side and low-side MOSFETs of a half-bridge

When the TLE92108-231QX receives a SPI to turn-off both the high-side and low-side MOSFETs of the half-bridge x (HBxMODE[1:0] = (0,0) or (1,1)):

- the gate of HSx and LSx are discharged with the current  $-ICHGSTx$  for the duration  $t_{HBxCCP Active}$  ([Figure 9](#))
- at the end of  $t_{HBxCCP Active}$ , the drive current of HSx and LSx are reduced to  $-IHOLD$

**Figure 9** Turn-off of the high-side and low-side MOSFETs of a half-bridge

*Note:* The CSN rising edge must be synchronized with the device logic. Therefore SPI commands are executed with a delay of up to 3  $\mu$ s after the CSN rising edge.

## Floating gate drivers

### 6.3 PWM operation with bridge driver in active mode (**BD\_PASS** = 0)

The TLE92108-231QX integrates three PWM channels. The pins PWM1, PWM2 and PWM3 provide the PWM signal for each PWM channel.

One half-bridge can be mapped to one of the PWM channels according to the settings of the control registers **HBMODE** and **PWMSET** (see **Table 11**):

- PWMxEN in **PWMSET**, enables or disables the PWM channel x
- The control bits PWMx\_HB[2:0] in **PWMSET** select the half-bridge
- The control bits HBMODE[1:0] (**HBMODE**) of the half-bridge selected by PWMx\_HB[2:0] configures the low-side or the high-side MOSFET in PWM mode

Example: the following bits must be set to map the low-side of HB3 to the PWM channel 2 (start sequence with PWM):

1. Set HB3MODE[1:0] to (0,0): HB3 is in high impedance
2. Set PWM2\_HB[2:0] to (0,1,0) and set PWM2EN to 1 (HB3 stays in high impedance, independently from the signal present at the PWM2 pin)
3. Set HB3MODE[1:0] to (0,1): PWM2 is applied to the low-side of HB3

**Table 11** PWM channel settings

PWMxEN <sup>1)</sup>	PWMx_HB[2:0] 1)	HByMODE[1:0] <sup>2)</sup>	PWMx channel setting <sup>1)</sup>
0 <sub>B</sub>	don't care	don't care	no PWM operation
don't care	don't care	00 <sub>B</sub>	no PWM operation on the selected HB
don't care	don't care	11 <sub>B</sub>	no PWM operation on the selection HB
1 <sub>B</sub>	000 <sub>B</sub>	01 <sub>B</sub>	Low-side of HB1 is mapped to PWMx
1 <sub>B</sub>	001 <sub>B</sub>	01 <sub>B</sub>	Low-side of HB2 is mapped to PWMx
1 <sub>B</sub>	010 <sub>B</sub>	01 <sub>B</sub>	Low-side of HB3 is mapped to PWMx
1 <sub>B</sub>	011 <sub>B</sub>	01 <sub>B</sub>	Low-side of HB4 is mapped to PWMx
1 <sub>B</sub>	100 <sub>B</sub>	01 <sub>B</sub>	Low-side of HB5 is mapped to PWMx

1 <sub>B</sub>	111 <sub>B</sub>	10 <sub>B</sub>	High-side of HB8 is mapped to PWMx

1) x = 1...3

2) the half-bridge y is selected by the PWMx\_HB[2:0] bits

## Floating gate drivers

**Note:** An SPI error is reported if one half-bridge is mapped to several activated PWM channels. In this case the external MOSFETs of the impacted half-bridge are turned-off and the corresponding status bit (HBxPWME) of the **HBVOUT\_PWMERR** register is set.

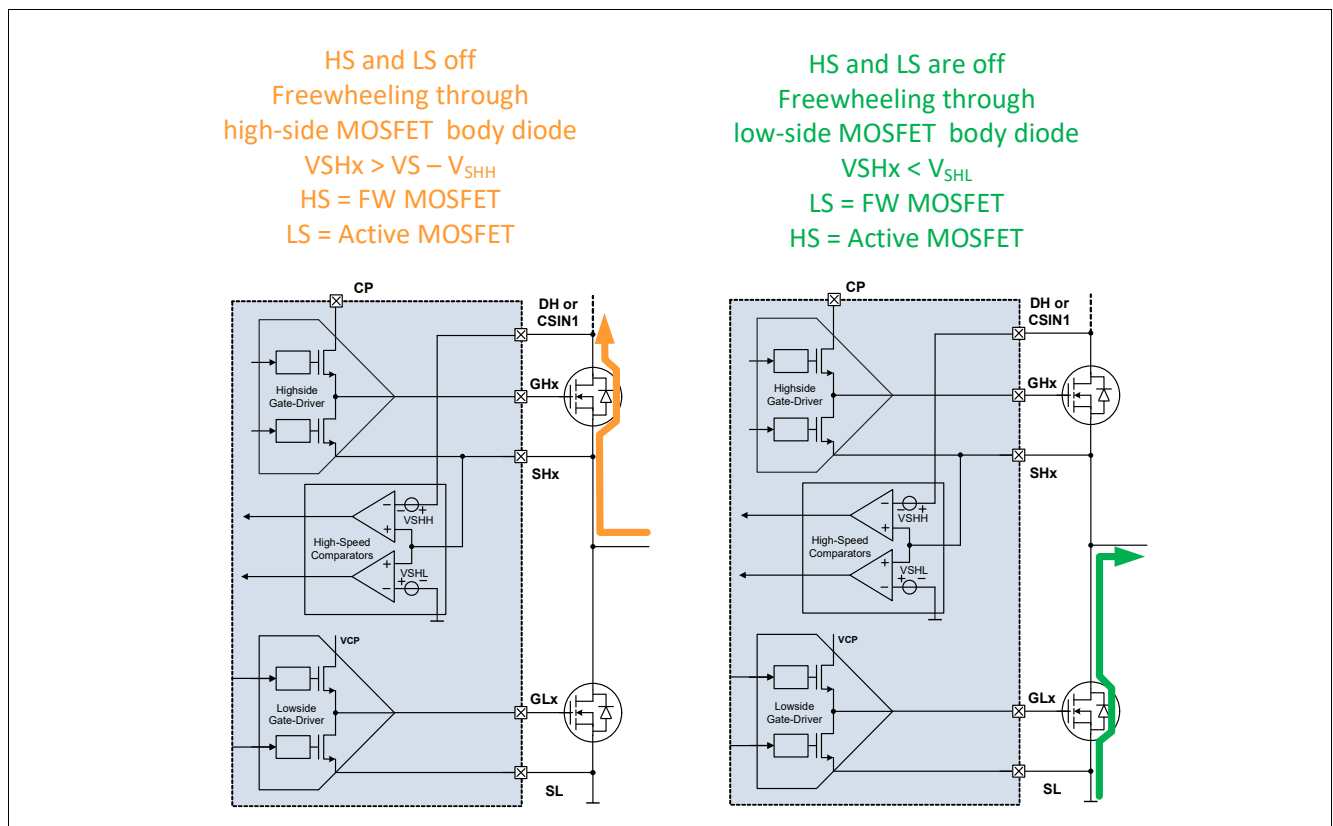

### 6.3.1 Determination of the active and free-wheeling MOSFET

An active free-wheeling is automatically implemented when a half-bridge is activated in PWM mode to reduce the power dissipation of the free-wheeling (FW) MOSFET: If the active MOSFET is OFF, the opposite (free-wheeling) MOSFET of the same half-bridge is actively turned on. See [Figure 11](#), [Figure 12](#), [Figure 13](#), [Figure 14](#), .

If **EN\_GEN\_CHECK** = 0: the PWM MOSFET is considered as the active MOSFET and the opposite MOSFET of the same half-bridge is considered as the free-wheeling MOSFET.

If **EN\_GEN\_CHECK** = 1: At the end of the cross-current protection times (tHBxCCP Active, tHBxCCP FW) of each MOSFET (both MOSFETs are supposed to be off) the device detects which MOSFET of the half-bridge is the active MOSFET and which MOSFET is the FW MOSFET ([Figure 10](#)).

- If  $V_{SHx} > V_{SHH}$ : The high-side MOSFET is the FW MOSFET and the low-side MOSFET is the active MOSFET
- If  $V_{SHx} < V_{SHL}$ : Then the low-side MOSFET is the FW MOSFET and the high-side MOSFET is the active MOSFET
- If  $V_{SHL} < V_{SHx} < V_{SHH}$ : No clear distinction between the FW MOSFET and the active MOSFET. The MOSFET to be turned on is considered as the active MOSFET.

**Figure 10** Detection principle of the active and freewheeling MOSFET

## Floating gate drivers

**Note:** The PWM signal is applied to the MOSFET selected by HBxMODE[1:0], independently from the free-wheeling and the active MOSFET.

**Note:** It is not possible to determine the active or FW MOSFET if the PWM on-time is shorter than  $t_{HBxCCP\ FW}$ , or if the PWM-off-time is shorter than  $t_{HBxCCP\ Active}$  (Refer to [Chapter 6.3.5](#)). In this case, the PWM MOSFET is considered as the active MOSFET. In other words, it is assumed that the motor operates as load.

**Figure 11, Figure 12** show examples of free-wheeling and active MOSFET when the motor operates as load.

**Figure 11** Active freewheeling on HB1: PWM1EN = 1. PWM applied to HS1 (HB1MODE[1:0] = 10<sub>B</sub>). The motor operates as load: HS1 is the active MOSFET, LS1 is the FW MOSFET.

**Figure 12** Active freewheeling on HB2: PWM1EN = 1. PWM applied to LS2 (HB2MODE[1:0] = 01<sub>B</sub>).

## Floating gate drivers

The motor operates as load: LS2 is the active MOSFET, HS2 is the FW MOSFET.

Figure 13 and Figure 14 show examples of free-wheeling and active MOSFET when the motor operates as generator.

Figure 13 Active freewheeling on HB1: PWM1EN = 1. PWM applied to HS1 (HB1MODE[1:0] = 10<sub>B</sub>). The motor operates as generator: LS1 is the active MOSFET, HS1 is the FW MOSFET.

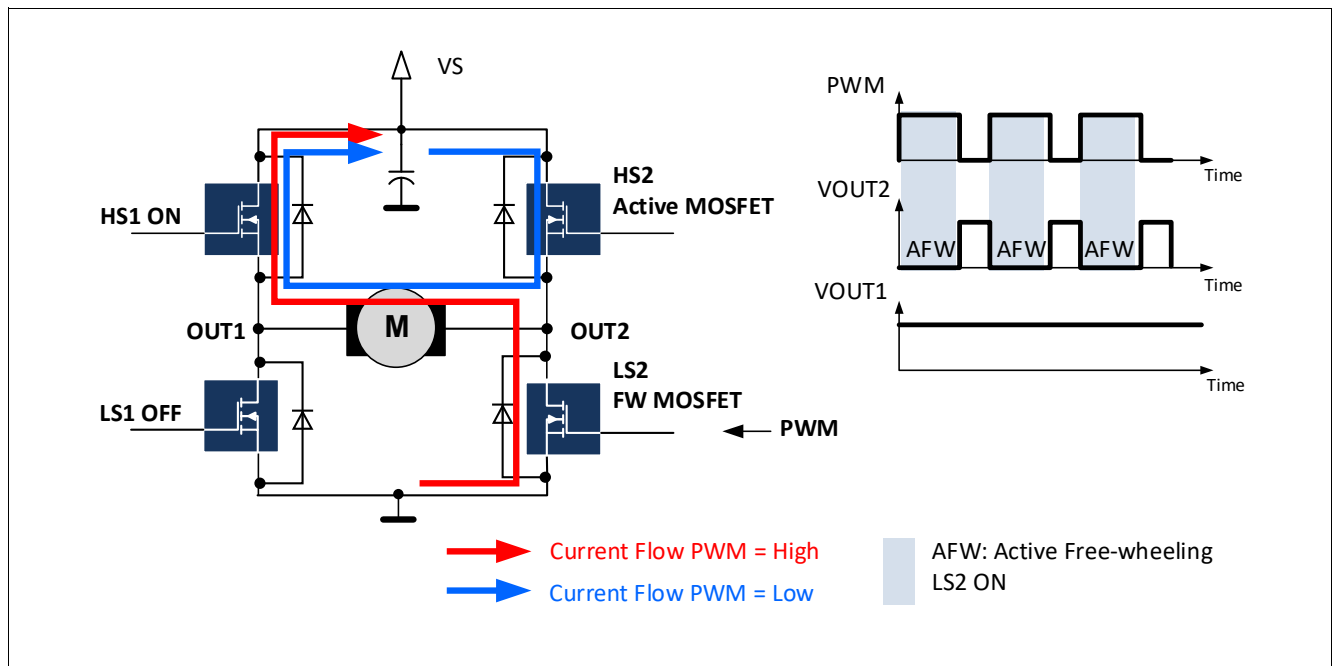

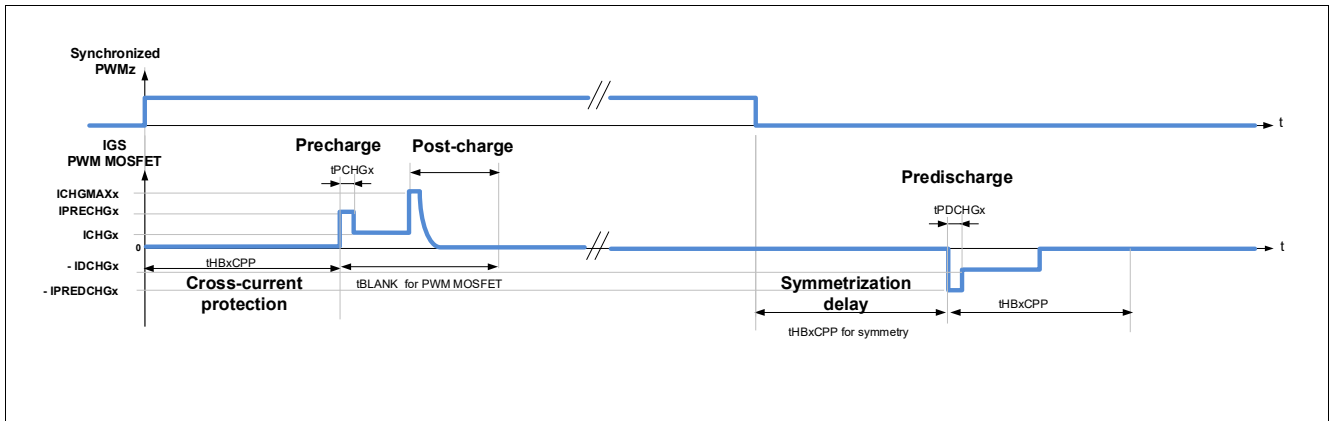

Figure 14 Active freewheeling on HB2: PWM1EN = 1. PWM applied to LS2 (HB2MODE[1:0] = 01<sub>B</sub>). The motor operates as generator: HS2 is the active MOSFET, LS2 is the FW MOSFET.

## Floating gate drivers

### 6.3.2 Configuration in PWM mode

The following sections describe the different control schemes in PWM mode. They differ during the pre-charge and pre-discharge phases (**Figure 15**):

- Adaptive gate control (AGC[1:0] = (1,0) or (1,1), **GENCTRL2**): in this mode a pre-charge current and a pre-discharge current are applied to the gate of the PWM MOSFET. These currents are used to regulate the effective turn-on and turn-off delays to the respective target values. Refer to **Chapter 6.3.3**.
- No adaptive gate control (AGC[1:0] = (0,0)): in this mode, the pre-charge and pre-discharge phases are deactivated. Refer to **Chapter 6.3.4.1**.
- No adaptive gate control (AGC[1:0] = (0,1)). In this mode:
  - the pre-charge phase is deactivated
  - during the pre-discharge phase, the gate of the PWM MOSFET mapped to the PWM channel x, x = 1...3, is discharged with the configured current IPCHGINIT (Refer to **PWM\_PCHG\_INIT** and **Chapter 6.3.4.2**)

**Figure 15** PWM overview showing pre-charge, pre-discharge and post charge phases, AGC[1:0] = 10<sub>B</sub> or 11<sub>B</sub>, POCHGDIS = 1<sub>B</sub>.

## Floating gate drivers

### 6.3.3 PWM operation with adaptive gate control

This section describes the MOSFETs control during high-side or low-side PWM operation when the adaptive gate control is enabled ( $AGC[1:0] = (1,0)$  or  $(1,1)$ , [GENCTRL2](#)).

*Note: Unless otherwise specified, the description of the regulation of the pre-charge and pre-discharge currents are applicable for*

Refer to [Chapter 6.3.1](#) for the definition of the active and of the freewheeling MOSFET according to the setting of [AGC](#).

Assumption: a high-side or low-side MOSFET driver is mapped to the PWM channel  $z$ ,  $z = 1, 2$  or  $3$ .

Refer to [Figure 16](#) for high-side PWM and [Figure 19](#) for low-side PWM for the description of the switching phase.

The TLE92108-231QX adapts the pre-charge current, respectively the pre-discharge current, in order to match the effective turn-on delay ( $t_{DON}$ ) and turn-off delay ( $t_{DOFF}$ ) to the configured values.

The configured turn-on and turn-off delays of the respective PWM MOSFETs are set by the registers [TDON\\_OFF1](#), [TDON\\_OFF2](#), [TDON\\_OFF3](#).

The effective turn-on and turn-off delays of the respective active MOSFETs are read out from the status registers [EFF\\_TDON\\_OFF1](#), [EFF\\_TDON\\_OFF2](#), [EFF\\_TDON\\_OFF3](#).

**Table 12 Abbreviations for adaptive turn-on and turn-off phases in PWM configuration**

Abbreviation	Definition
Suffix $x$	Related to the half-bridge $x$ ( $x = 1 \dots 8$ )
Suffix $z$	Related to the PWM channel $z$ ( $z = 1, 2$ or $3$ )
VGS_HS $x$	Gate-Source voltage of high-side MOSFET $x$
IGS_HS $x$	Gate current of high-side MOSFET $x$ IGS_HS $x$ is positive when the current flows out of GH $x$ .
VGS_LS $x$	Gate-Source voltage of low-side MOSFET $x$
IGS_LS $x$	Gate current of low-side MOSFET $x$ IGS_LS $x$ is positive when the current flows out of GL $x$ .
tHBxCCP ACTIVE	Active cross-current protection time of HB $x$ . See control registers <a href="#">CCP_BLK1</a> , <a href="#">CCP_BLK2_ACT</a> , <a href="#">PWM_ICHGMAX_CCP_BLK3_ACT</a> and <a href="#">Chapter 7.4</a> .
tHBxBLANK ACTIVE	Active Drain-source overvoltage blank time of HB $x$ . See control registers <a href="#">CCP_BLK1</a> , <a href="#">CCP_BLK2_ACT</a> , <a href="#">PWM_ICHGMAX_CCP_BLK3_ACT</a> and <a href="#">Chapter 7.4</a> .
tHBxCCP FW	Freewheeling cross-current protection time of HB $x$ . See control registers <a href="#">CCP_BLK1</a> , <a href="#">CCP_BLK2_FW</a> , <a href="#">PWM_ICHGMAX_CCP_BLK3_FW</a> and <a href="#">Chapter 7.4</a>
tHBxBLANK FW	Freewheeling drain-source overvoltage blank time of HB $x$ . See control registers <a href="#">CCP_BLK1</a> , <a href="#">CCP_BLK2_FW</a> , <a href="#">PWM_ICHGMAX_CCP_BLK3_FW</a> and <a href="#">Chapter 7.4</a>
PWM $z$	External PWM signal applied to the input pin PWM $z$ .
ICHGMAX $z$	Maximum drive current of the half-bridge mapped to PWM channel $z$ during the pre-charge and pre-discharge phases. See control registers <a href="#">PWM_ICHGMAX_CCP_BLK3_ACT</a> and <a href="#">PWM_ICHGMAX_CCP_BLK3_FW</a> ICHGMAX $z$ is also the drive current for the post-charge phase IPRECHG $z$ and IPREDCHG $z$ are limited to ICHGMAX $z$ .

**Floating gate drivers**

**Table 12 Abbreviations for adaptive turn-on and turn-off phases in PWM configuration**

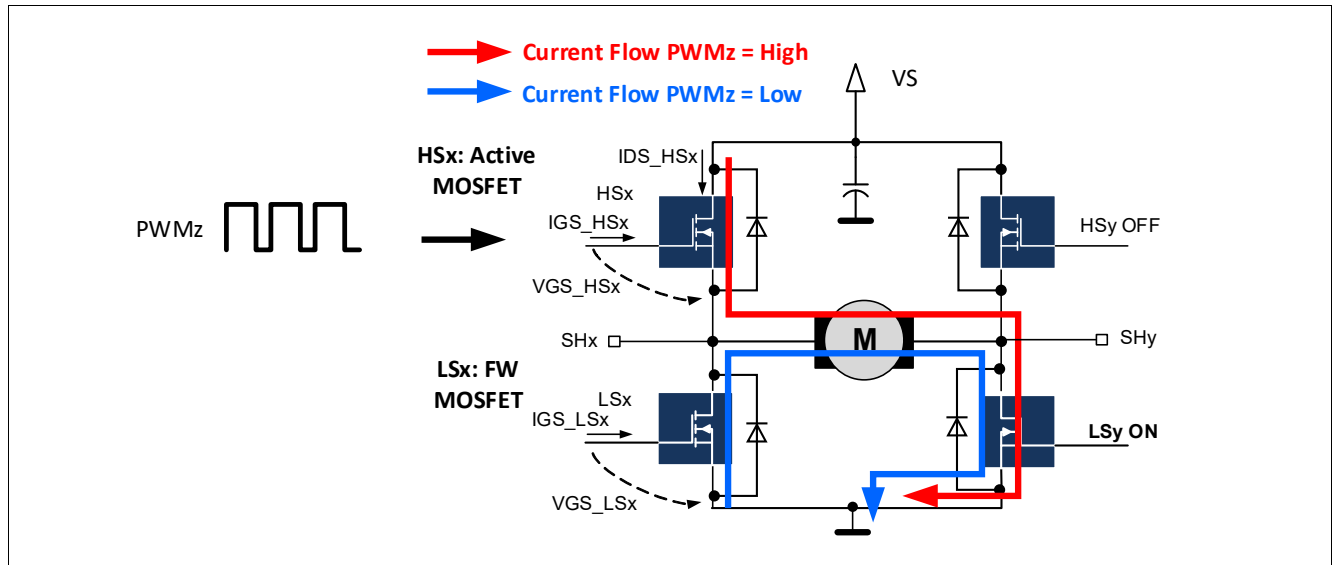

Abbreviation	Definition
IPRECHGz	Pre-charge current sourced by the gate driver mapped to the PWM channel z during tPCHGz. Internal and self-adaptive parameter (if <b>AGC</b> = (1,0) or (1,1), <b>GENCTRL2</b> ) IPRECHGz is clamped between $I_{CHG0}$ and ICHGMAXz.
IPCHGINITz	Initial value of IPRECHGz. Refer to <b>PWM_PCHG_INIT</b>
IPREDCHGz	Pre-discharge-current sunk by the gate driver mapped to the PWM channel z during tPDCHGz. Internal and self-adaptive parameter. ( <b>AGC</b> = (1,0) or (1,1), <b>GENCTRL2</b> ) IPREDCHGz is clamped between $I_{DCHG0}$ and IDCHGMAXz.
IPDCHGINITz	Initial value of IPREDCHGz. Refer to <b>PWM_PDCHG_INIT</b>
ICHGz	Current sourced by the gate driver mapped to the PWM channel z during the charge phase. See control register <b>PWM_ICHG_ACT</b> .
IDCHGz	Current sunk by the gate driver mapped to the PWM channel z during the discharge phase. See control register <b>PWM_IDCHG_ACT</b> .
ICHGFWz	Current source or sunk by the gate driver to turn on / turn off the freewheeling MOSFET of the half-bridge mapped to the PWM channel z. See <b>PWM_ICHG_ACT</b> .
tPCHGz	Duration of the pre-charge phase of PWM channel z. tPCHGz is configurable by SPI. See control register <b>TPRECHG</b> , configuration bits TPCHGz[1:0].
tPDCHGz	Duration of the pre-discharge phase of PWM channel z. tPDCHGz is configurable by SPI. See control register <b>TPRECHG</b> , configuration bits TPDCCHGz[1:0].
tDONz	Turn-on delay of the PWM MOSFET mapped to the PWM channel z: <ul style="list-style-type: none"> <li>for high-side PWM: time between the end of the cross-current protection and when VSHx increases to <math>V_{SHL}</math> (<b>Figure 17</b>).</li> <li>for low-side PWM: time between the end of the cross-current protection and when VSHx decreases to <math>V_{SHH}</math>.</li> </ul>
tDOFFz	Turn-off delay of the PWM MOSFET mapped to the PWM channel z: <ul style="list-style-type: none"> <li>for high-side PWM: time between the end of the symmetrization delay (<math>t_{HBxCCP}</math>) and when VSHx decreases to VSHH (<b>Figure 18</b>).</li> <li>for low-side PWM: time between the end of the symmetrization delay (<math>t_{HBxCCP}</math>) and when VSHx increases to VSHL.</li> </ul>
IHOLD	Hold current sourced or sunk by the gate driver to keep the MOSFET in the desired state. See IHOLD control bit in <b>GENCTRL2</b> .
IHARDOFF	IHARDOFF is the maximum current that the gate drivers can sink. It corresponds to the discharge current when IDCHGx[4:0] = 31 <sub>D</sub> (100 mA typ.).
TFVDS	Drain-Source overvoltage filter time. See <b>GENCTRL2</b> .

## Floating gate drivers

### 6.3.3.1 High-side PWM with adaptive gate control, motor operating as load

The following section describes the MOSFET control when the PWM signal is applied to the high-side MOSFET of one half-bridge while the motor operates .

Assumption: the PWM channel  $z$ ,  $z = 1, 2$  or  $3$ , is applied to the high-side MOSFET of the half-bridge  $x$ ,  $x = 1 \dots 8$ .

**Figure 16** PWM channel  $z$  is mapped to high-side  $x$ , motor operating as load

**Floating gate drivers**

**Figure 17 Adaptive turn-on, high-side PWM, AGC[1:0] = (1,0) or (1,1), motor operating as load**

## Floating gate drivers

### Adaptive turn-on during high-side PWM

The turn-on of the high-side MOSFET is done in four phases (Refer to [Figure 17](#)):

1. **Cross-current protection phase:** The cross-current protection tHBxCCP FW starts at the rising edge of the internal PWMz signal<sup>1)</sup>. During tHBxCCP FW, the low-side MOSFET x is turned off with the discharge current - ICHGFWx, while the high-side MOSFET x is kept off. .
2. **Pre-charge:** Once tHBxCCP FW has elapsed, the gate of the high-side MOSFET x is pre-charged with the current IPRECHGz for a duration tPCHGz. IPRECHGz<sup>2)</sup> is an internal parameter, which is self-adaptive (see next phase).
3. **Charge:** After tPCHGz, the charge current is decreased from IPRECHGz down to ICHGz. The effective tDONz<sup>3)</sup> is measured and compared to the configured tDONz for the automatic adaptation of IPRECHGz (see [Adaptive control of pre-charge current](#)). The charge phase ends up when  $V_{SHx}$  reaches  $V_{SHH}$ .
4. **Post-charge:** After the charge phase, the control signal for the charge current of HSx is increased by one current step every 62.5 ns typ. to ICHGMAXx.

*Note:* The postcharge phase is deactivated by setting [POCHGDIS](#) to 1. Refer to [GENCTRL2](#).

### Adaptive control of pre-charge current

Refer to [Chapter 6.3.6](#) for information on the pre-discharge currents.

The pre-charge current IPRECHGz is a self-adaptive parameter if AGC[1:0] = (1,0) or (1,1) (see [GENCTRL2](#)). It is applied during tPCHGz (see [TPRECHG](#)). The TLE92108-231QX adapts IPRECHGz to match the effective tDONz to the configured value.

IPRECHGz is clamped between  $I_{CHG0}$  (1 mA typ.) and ICHGMAXz (see [PWM\\_ICHGMAX\\_CCP\\_BLK3\\_ACT](#)).

IPRECHGz is initialized to min(IPCHGINITz, ICHGMAXz) (refer to [PWM\\_PCHG\\_INIT](#)) when the TLE92108-231QX receives an SPI command setting PWMz\_EN to 1 (see [PWMSET](#)).

The following adaptive schemes can be selected:

AGCFILT = 0 ([GENCTRL2](#)): No filter is applied

- If the effective tDONz is longer than the configured tDONz, then IPRECHGz is increased during the next pre-charge phase.
- If the effective tDONz is shorter than the configured tDONz, then IPRECHGz is decreased during the next pre-charge phase.
- The pre-charge current is increased or decreased by one, respectively by two current steps ([Chapter 6.3.6](#)) if the control bit IPCHGADT in the control register [GENCTRL1](#) is set to 0 respectively 1.

AGCFILT = 1: The filter is applied

- If the effective tDONz **of the last two PWM cycles** are longer than the configured tDONz, then IPRECHGz is increased during the next pre-charge phase.

1) The external PWMz signal is synchronized with the internal device clock, resulting in the delay  $t_{PWM\_SYNCH}$  between the internal and the external PWMz signals.

2) IPRECHGz is clamped between ICHGMAXz and  $I_{CHG0}$ .

3) The effective tDON can be read out. Refer to [EFF\\_TDON\\_OFF1](#), [EFF\\_TDON\\_OFF2](#), [EFF\\_TDON\\_OFF3](#)

### **Floating gate drivers**

- If the effective tDONz **of the last two PWM cycles** are shorter than the configured tDONz, then IPRECHGz is decreased during the next pre-charge phase.
- The pre-charge current is increased or decreased by one, respectively by two current steps ([Chapter 6.3.6](#)) if the control bit IPCHGADT in the control register **GENCTRL1** is set to 0 respectively 1.
- If none of the two cases are applicable, then IPRECHGz is unchanged during the next pre-charge phase.

## Floating gate drivers

**Figure 18 Adaptive turn-off, high-side PWM, AGC[1:0] = (1,0) or (1,1), motor operating as load**

## Adaptive turn-off during high-side PWM

## Floating gate drivers

The turn-off of the high-side MOSFET is done in four phases (Refer to [Figure 18](#)):

1. **Turn-off delay time for symmetrization** of the PWM signal: The turn-off of HSx is delayed by tHBxCCP FW after the falling edge of the internal PWMz signal<sup>1)</sup>, in order to compensate the distortion caused by the cross-current protection time at turn-on.
2. **Pre-discharge**: once tHBxCCP FW for symmetrization has elapsed, the gate of the high-side MOSFET x is pre-discharged with the current - IPREDCHGz for a duration tDPCHGz. IPREDCHGz is a device internal parameter, which is self-adaptive (See next phase).
3. **Discharge**: After tPREDCHGz, the pre-discharge current is decreased in absolute value from IPREDCHGz<sup>2)</sup> down to IDCHGz. The effective tDOFF<sup>3)</sup> is measured and compared to the configured tDOFFz for the automatic adaptation of IPREDCHGz (see [Adaptive control of pre-discharge current](#)). The discharge phase ends up at expiration of tHBxCCP active for cross-current protection.
4. **Cross-current protection phase**: The cross-current protection is concurrent to the pre-discharge and discharge of the high-side MOSFET. The cross-current protection phase starts when the turn-off delay for symmetrization ends up. It has the duration tHBxCCP active. During tHBxCCP active, the low-side MOSFETx is kept OFF. When tHBxCCP active has elapsed, the gate of the low-side MOSFET x is charged with the current ICHGFWz until the end of tFVDS, provided that  $V_{SHx} < V_{SHL}$ .

### Adaptive control of pre-discharge current

Refer to [Chapter 6.3.6](#) for information on the pre-discharge currents.

The pre-discharge current IPREDCHGz is a self-adaptive parameter if AGC[1:0] = (1,0) or (1,1) (see [GENCTRL2](#)). The TLE92108-231QX adapts the IPREDCHGz to match the measured  $t_{DOFFz}$  to the configured value.

IPREDCHGz is clamped between  $I_{DCHG0}$  (1 mA typ.) and ICHGMAXz (see [PWM\\_ICHGMAX\\_CCP\\_BLK3\\_ACT](#)).

IPREDCHGz is initialized to min(IPDCHGINITz, ICHGMAXz) (refer to [PWM\\_PDCHG\\_INIT](#)) when the TLE92108-231QX receives a SPI command setting PWMz\_EN to 1 (see [PWMSET](#))

The pre-discharge current is increased or decreased by one, respectively by two current steps ([Chapter 6.3.6](#)) if the control bit IPCHGADT in the control register [GENCTRL1](#) is set to 0 respectively 1.

The following adaptive schemes can be selected:

AGCFILT = 0 ([GENCTRL2](#)): No filter is applied

- If the effective tDOFFz is longer than the configured tDOFFz, then IPREDCHGz is increased during the next pre-discharge phase
- If the effective tDOFFz is shorter than the configured tDOFFz, then IPREDCHGz is decreased during the next pre-discharge phase
- The pre-charge current is increased or decreased by one, respectively by two current steps ([Chapter 6.3.6](#)) if the control bit IPCHGADT in the control register [GENCTRL1](#) is set to 0 respectively 1.

AGCFILT = 1: The filter is applied

1) The external PWMz signal is synchronized with the internal device clock, resulting in the delay  $t_{PWM\_SYNCH}$  between the internal and the external PWMz signals.

2) IPREDCHGz is clamped between ICHGMAXz and  $I_{DCHG0}$ .

3) The effective tDOFF can be read out. Refer to [EFF\\_TDON\\_OFF1](#), [EFF\\_TDON\\_OFF2](#), [EFF\\_TDON\\_OFF3](#).

### **Floating gate drivers**

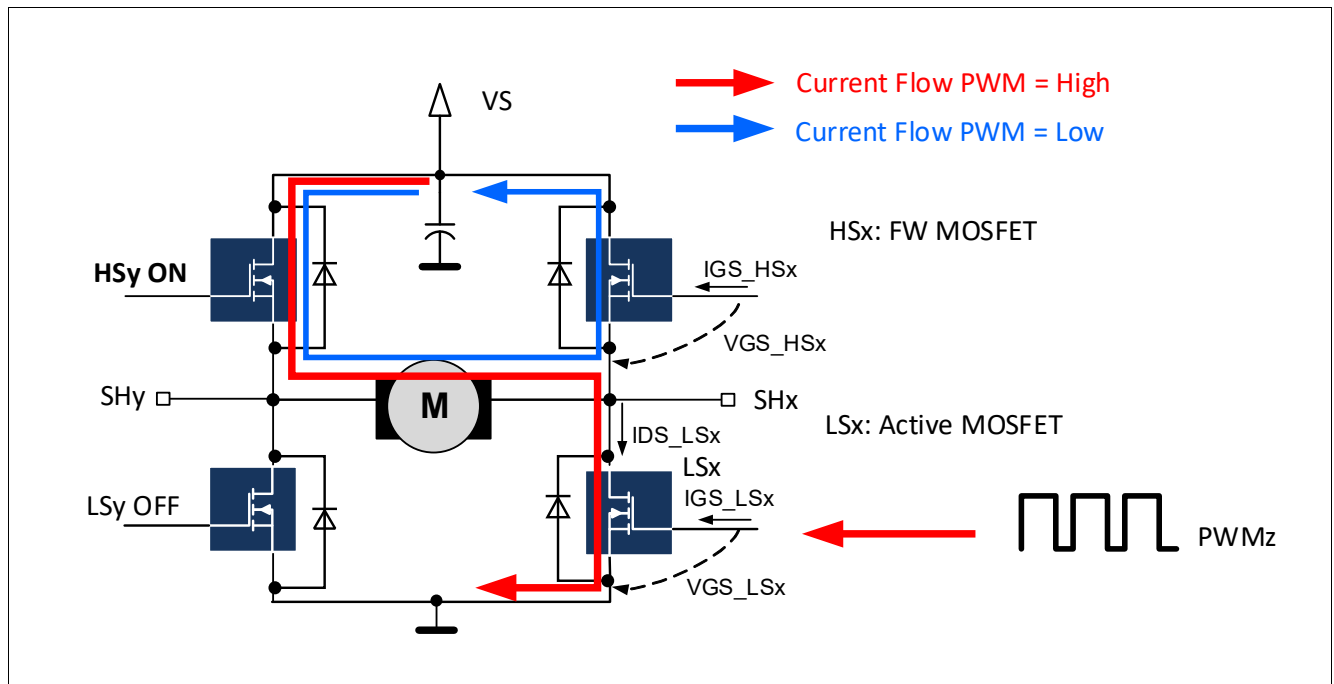

- If the effective tDOFFz **of the last two PWM cycles** are longer than the configured tDOFFz, then IPREDCHGz is increased during the next pre-charge phase.
- If the effective tDOFFz **of the last two PWM cycles** are shorter than the configured tDOFFz, then IPREDCHGz is decreased during the next pre-charge phase.
- If none of the two cases are applicable, then IPRECHGz is unchanged during the next pre-charge phase.
- The pre-charge current is increased or decreased by one, respectively by two current steps if the control bit IPCHGADT is set to 0 respectively 1.

## Floating gate drivers

### 6.3.3.2 Low-side PWM with adaptive gate control, motor operating as load

The following section describes the MOSFET control when the PWM signal is applied to the low-side MOSFET of one half-bridge.

Assumption: the PWM channel  $z$ ,  $z = 1, 2$  or  $3$ , is applied to the low-side MOSFET of the half-bridge  $x$ ,  $x = 1 \dots 8$  (**Figure 19**).

**Figure 19** PWM Channel  $z$  is mapped to low-side  $x$ , motor operating as load

The description of the control of the PWM half-bridge differs from the description of **Chapter 6.3.3.1** only by exchanging high-side  $x$  and low-side  $x$  and the thresholds  $V_{SHH}$  and  $V_{SHL}$ .

Floating gate drivers

Figure 21 Adaptive turn-on, high-side PWM, AGC[1:0] = (1,0) or (1,1), motor operating as generator

Floating gate drivers

Figure 23 Adaptive turn-off with high-side PWM, AGC[1:0] = (1,0) or (1,1), motor operating as generator

## Floating gate drivers

### 6.3.3.5 Status bits for regulation of turn-on and turn-off delay times

The control bits TDREGx (**GENSTAT**) indicate if tDONx and tDOFFx of the PWM channel x using the adaptive gate control scheme (AGC[1:0] = 10<sub>B</sub> or 11<sub>B</sub>) is in regulation.

The PWM channel is considered in regulation if one of the following conditions are met:

- the effective turn-on and turn-off delays are equal to the configured delays for at least eight consecutive PWM cycles
- the error between the effective and configured delay changes its sign at least three times during the last 8 PWM cycles

### 6.3.3.6 Precharge and predischage phases with **EN\_DEEP\_AD = 1**

This section is valid if **EN\_DEEP\_AD** = 1. Enabling this feature leads to a lower granularity of the resulting precharge and and predischage currents.

This principle is illustrated with an example during the precharge phase on **Figure 24**. The same principle is applied to the predischage phase.

If **EN\_DEEP\_AD** = 1:

- The precharge phase can be divided in two parts, during which different precharge current steps are applied
- The predischage phase can be divided in two parts, during which different predischage current steps are applied

The device exits the “deep adaptation mode” if  $t_{\text{DON}}$ , respectively  $t_{\text{DOFF}}$ , cannot be regulated and the resolution of the precharge time cannot be further divided. Then, one single current step is applied during the precharge time (**Figure 25**).

Floating gate drivers

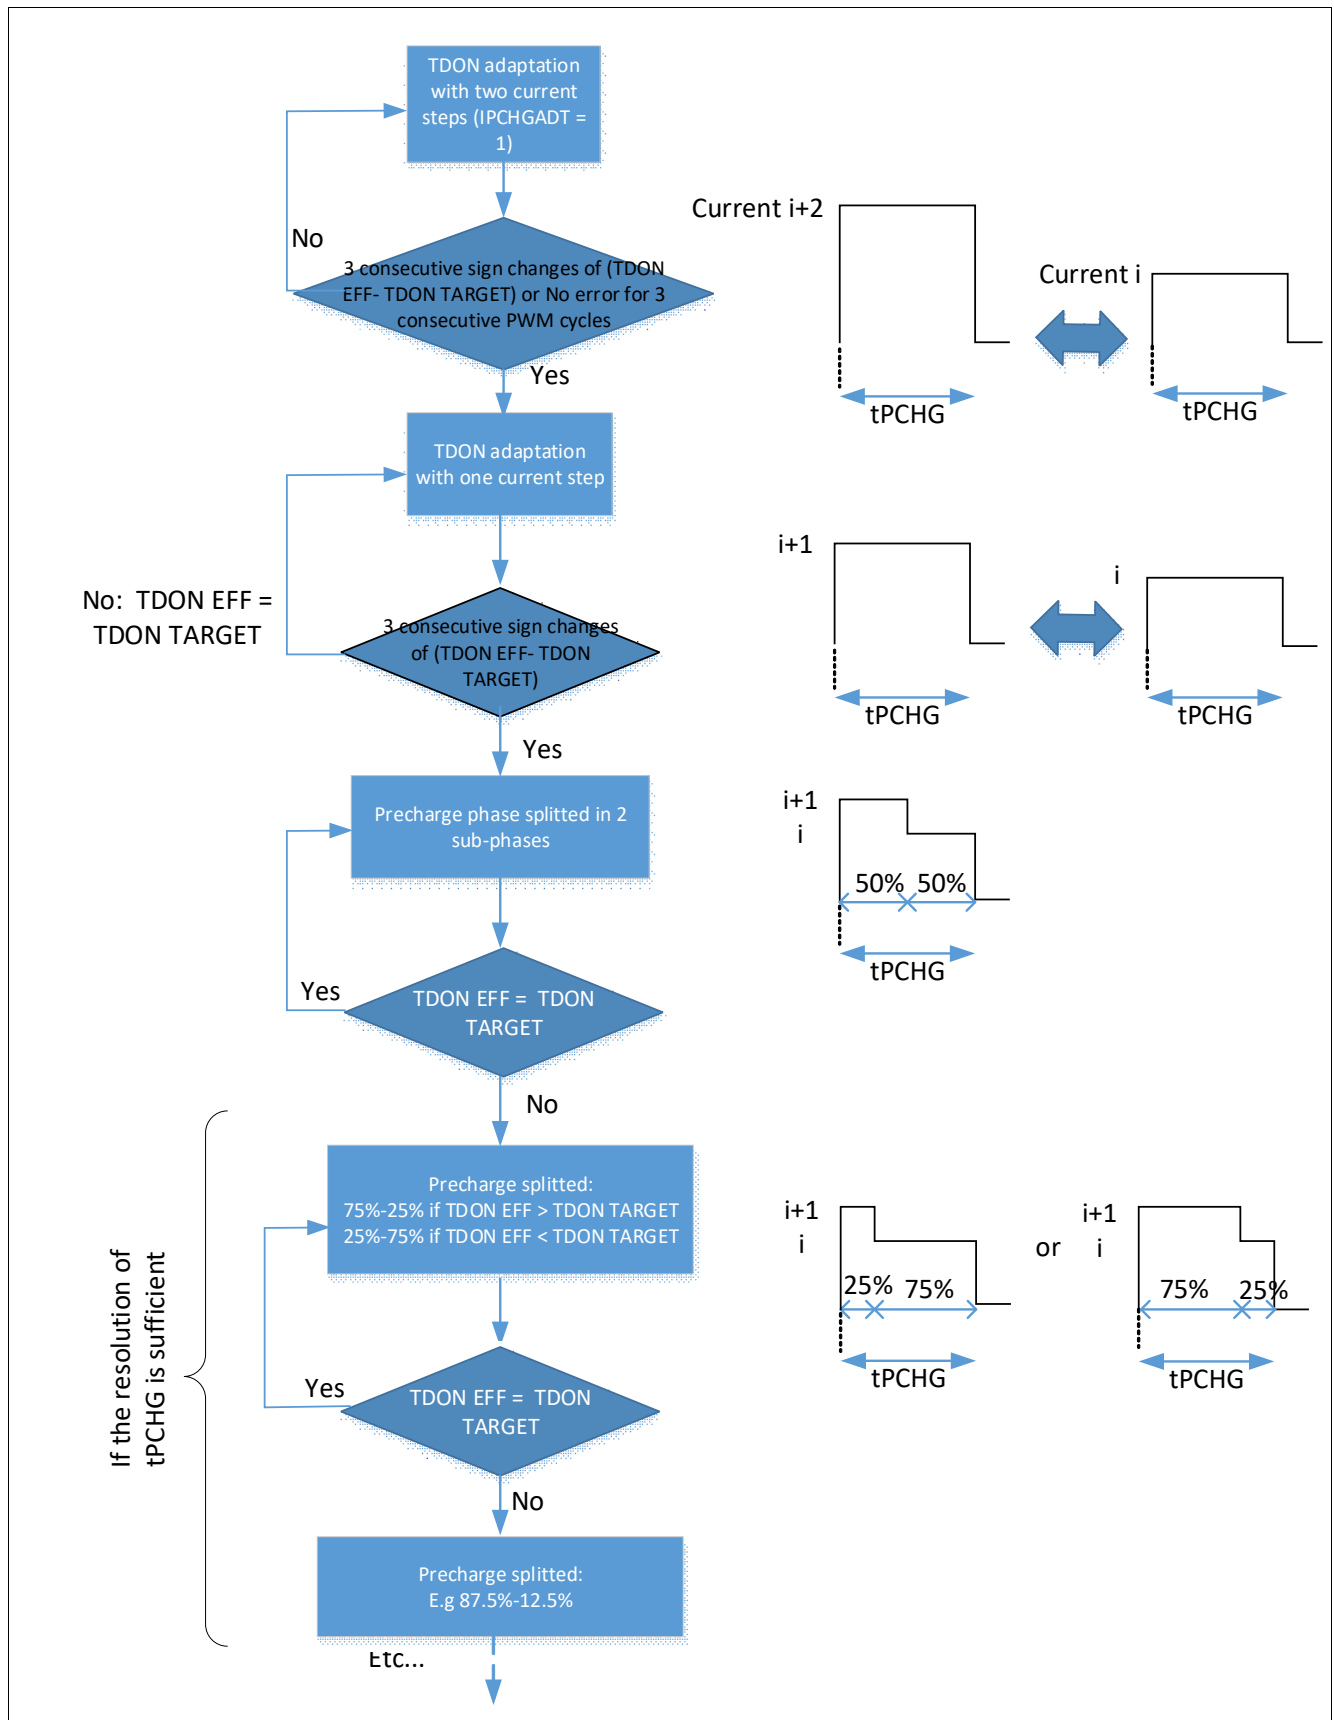

Figure 24 Example of precharge current modulation during the precharge phase,  $EN\_DEEP\_AD = 1$

Floating gate drivers

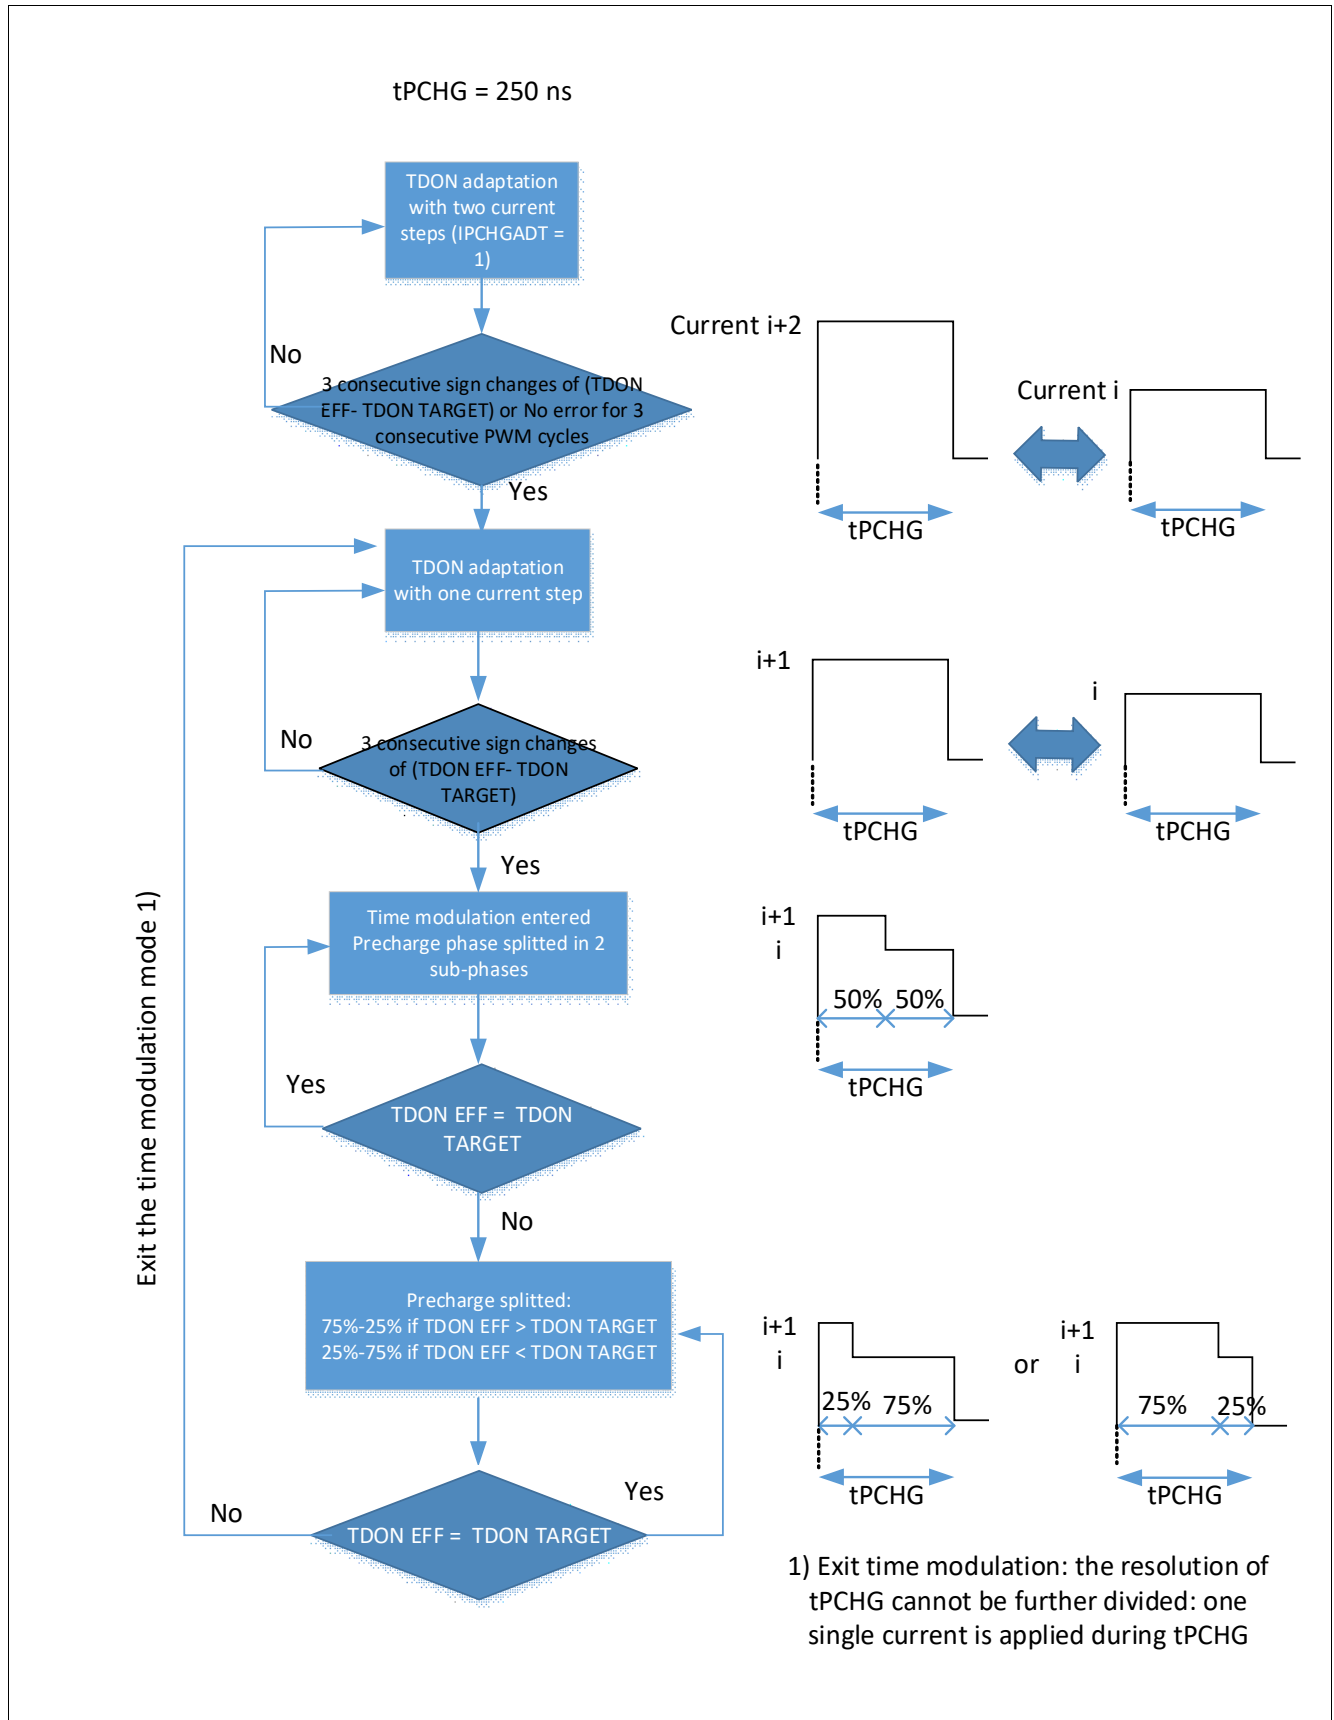

Figure 25 Criteria to exit the time modulation,  $EN\_DEEP\_AD = 1$

## **Floating gate drivers**

### **6.3.4 PWM operation without adaptive gate control**

The adaptive gate control is disabled if AGC[1:0] is set to (0,0) or (0,1). The effective turn-on and turn-off delays of the PWM MOSFETs are not regulated. Two modes can be selected.

The target turn-on and turn-off delay times of PWM MOSFETs (configured in [TDON\\_OFF1](#), [TDON\\_OFF2](#), [TDON\\_OFF3](#)) are no longer regulated. Nevertheless the status registers [EFF\\_TDON\\_OFF1](#), [EFF\\_TDON\\_OFF2](#), [EFF\\_TDON\\_OFF3](#) still report the effective turn-on and turn-off times of the PWM MOSFET.

#### **6.3.4.1 PWM operation without adaptive gate control, AGC[1:0] = (0,0)**

When AGC[1:0] = (0,0) (see [GENCTRL2](#)), the control of the gate drivers in PWM mode differs from the description of [Chapter 6.3.3, PWM operation with adaptive gate control](#), only by the suppression of the pre-charge and pre-discharge phases.

**Floating gate drivers**

**6.3.4.2 PWM operation without adaptive gate control, AGC[1:0] = (0,1)**

When AGC[1:0] = (0,1) (see [GENCTRL2](#)), the control of the gate drivers in PWM mode differs from the description of [Chapter 6.3.4.1, PWM operation without adaptive gate control, AGC\[1:0\] = \(0,0\)](#), only by the addition of a pre-discharge phase. During tPDCHGz, the gate of the PWM MOSFET mapped to the PWM channel z is discharged with the current -IPDCHGINITz (Refer to [PWM\\_PDCHG\\_INIT](#)).

Refer to [Figure 26](#) for the turn-off of the PWM MOSFET with high-side PWM.

## Floating gate drivers

**Figure 26** High-side PWM operation - turn-off without adaptive gate control, AGC[1:0] = (0,1)

## Floating gate drivers

### 6.3.5 PWM operation at high and low duty cycles

This section describes the internal PWM signal of the active and FW MOSFET when the motor operates as load or generator. In particular, at low and high duty cycles, the active free-wheeling is disabled.

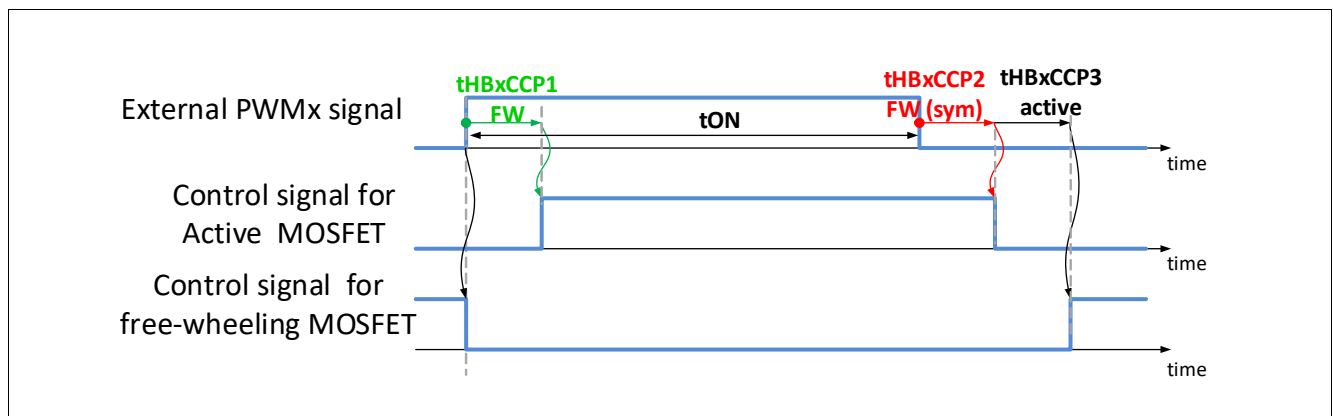

**Note:** It is recommended to clear **EN\_GEN\_CHECK** (**EN\_GEN\_CHECK** to 0) at very high and very low duty cycles:  $t_{ON} > t_{HBxCCP\ FW}$  and  $t_{OFF} < t_{HBxCCP\ active}$ . Under these conditions, a generator mode cannot be correctly detected. The control scheme of the active MOSFET and of the freewheeling MOSFET can therefore be inverted.

**Note:** The device cannot measure the switching times  $t_{DON}$ ,  $t_{DOFF}$ ,  $t_{RISE}$  and  $t_{FALL}$  at very high and very low duty cycles:  $t_{ON} > t_{HBxCCP\ FW}$  and  $t_{OFF} < t_{HBxCCP\ active}$ .

#### General case, motor operating as load, $t_{ON} > t_{HBxCCP\ FW}$ and $t_{OFF} > t_{HBxCCP\ active}$

**Figure 27** shows the internal control signals of the PWM MOSFETs and the freewheeling MOSFET while the motor operates as load :

- $t_{ON}$  is longer than the FW cross-current protection time ( $t_{HBxCCP\ FW}$ )
- $t_{OFF}$  is longer than the active cross-current protection time ( $t_{HBxCCP\ Active}$ )

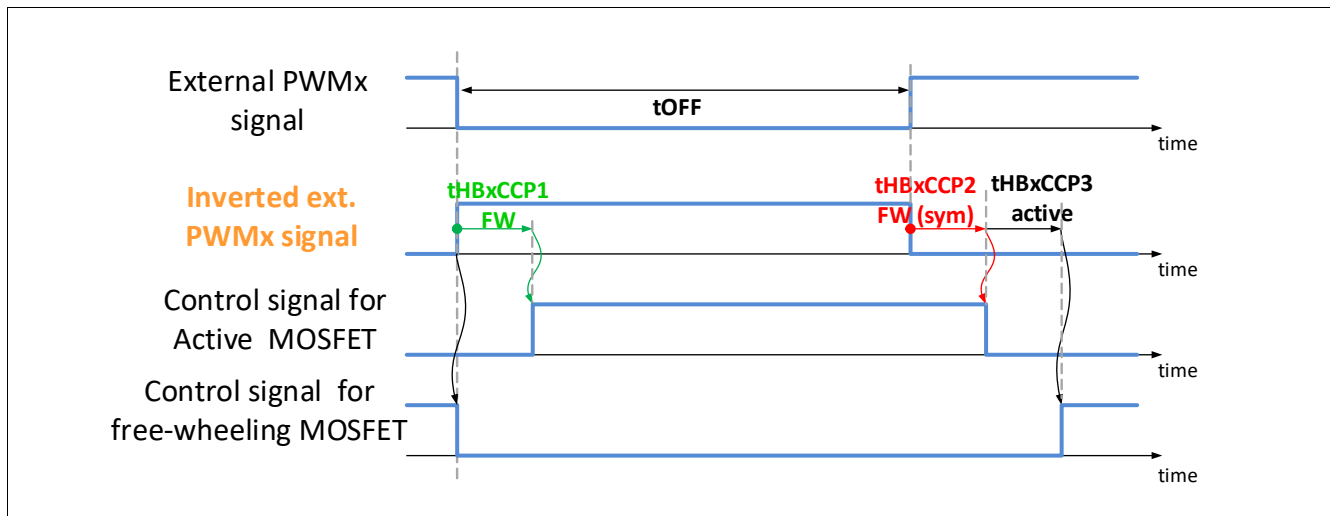

**Figure 27 Internal signals for PWM operation - General case  $t_{ON} > t_{HBxCCP\ FW}$ ,  $t_{OFF} > t_{HBxCCP\ active}$ , motor operating as load**

#### General case, motor operating as generator, $t_{OFF} > t_{HBxCCP\ FW}$ and $t_{ON} > t_{HBxCCP\ active}$

**Figure 28** shows the internal control signals of the PWM MOSFETs and the freewheeling MOSFET while the motor operates as generator:

- $t_{OFF}$  is longer than the FW cross-current protection time ( $t_{HBxCCP\ FW}$ )
- $t_{ON}$  is longer than the active cross-current protection time ( $t_{HBxCCP\ Active}$ )

**Floating gate drivers**

**Figure 28 Internal signals for PWM operation - General case:  $t_{OFF} > t_{HBxCCP\ FW}$ ,  $t_{ON} > t_{HBxCCP\ active}$ , motor operating as generator**

## Floating gate drivers

### High duty cycle: $t_{OFF} < t_{HBxCCP \text{ active}}$

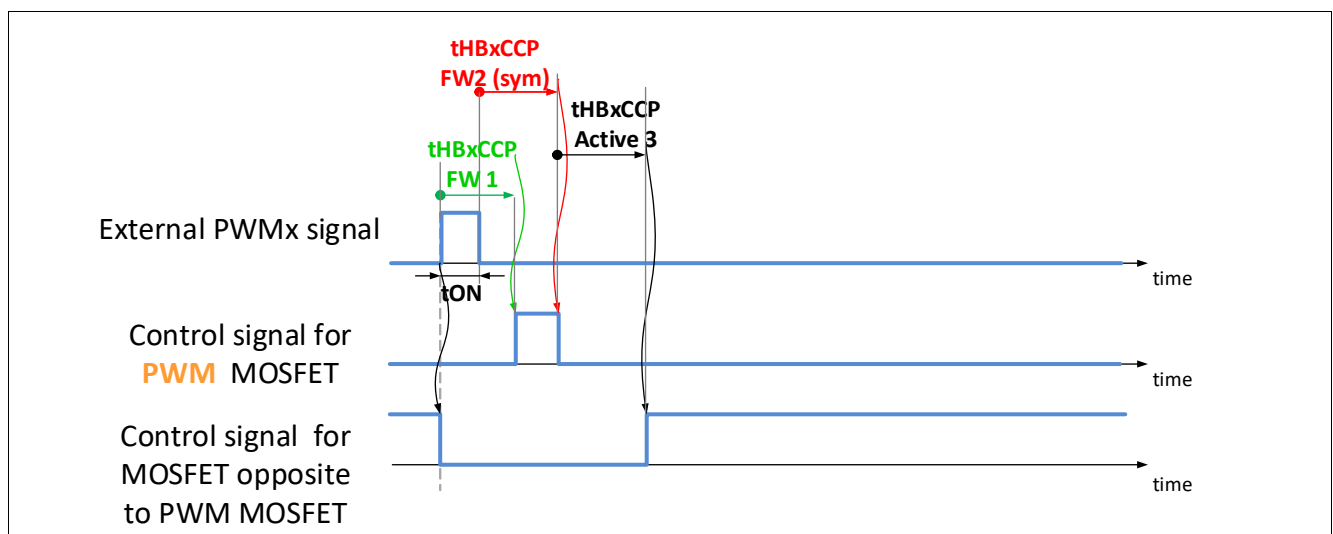

No distinction between active MOSFET and FW MOSFET is possible, when the OFF-time of the external PWM signal is shorter than the configured active cross-current protection time. Therefore the PWM MOSFET (selected by HBxMODE[1:0]) is controlled as the active MOSFET. In other words, it is assumed that the motor operates as load. The control signal of the PWM MOSFET is shifted by one FW cross-current protection time compared to the external PWM signal. The MOSFET opposite to the PWM MOSFET stays OFF (passive FW). Refer to [Figure 29](#).

**Figure 29** Internal signals for PWM operation at high duty cycle,  $t_{OFF} < t_{HBxCCP \text{ active}}$

### Low duty cycle: $t_{ON} < t_{HBxCCP \text{ FW}}$

No distinction between active MOSFET and FW MOSFET is possible, when the ON-time of the external PWM signal is shorter than the configured FW cross-current protection time. Therefore the PWM MOSFET (selected by HBxMODE[1:0]) is controlled as the active MOSFET. In other words, it is assumed that the motor operates as load. The control signal of the PWM MOSFET is shifted by one cross-current protection time compared to the external PWM signal. The MOSFET opposite to the PWM MOSFET stays off (passive FW). Refer to [Figure 30](#).

**Figure 30** Internal signals for PWM operation at low duty cycle,  $t_{ON} < t_{HBxCCP \text{ FW}}$

## Floating gate drivers

### 6.3.6 Gate driver current

Each gate driver is able to source and sink currents from 1.0 mA to 100 mA, with 32 steps according to [Figure 31](#) and [Figure 32](#).

The charge and discharge currents of the active and the FW MOSFETs are configured separately by:

- The **REG\_BANK** bit (**GENCTRL1**)
- The control registers **PWM\_ICHG\_ACT**, **PWM\_IDCHG\_ACT**, **PWM\_ICHG\_FW**

The charge current of the active MOSFETs are configured by **PWM\_ICHG\_ACT** (**REG\_BANK** = 0)

The discharge current of the active MOSFETs are configured by **PWM\_IDCHG\_ACT** (**REG\_BANK** = 0)

The charge and discharge current of the FW MOSFET are configured by **PWM\_ICHG\_FW** (**REG\_BANK** = 1)

1)  $V_{GS} \geq V_{GS(OFF)1}$  if IDCHGx  $\leq 14_D$ ,  $V_{GS} \geq V_{GS(OFF)2}$  if IDCHGxFW  $\geq 15_D$

## Floating gate drivers

### 6.4 Passive discharge

Resistors ( $R_{GGND}$ ) between the gate of GHx and GND, and between GLx and GND, ensure that the external MOSFETs are turned off, when EN = Low or when  $V_{DD} < V_{DDPOFFR}$ .

During normal mode with **BD\_PASS** bit reset (**GENCTRL2**) without failure causing the deactivation of the gate drivers, these pull-down resistors are switched off. The MOSFET are actively kept off with the discharge current IHOLD.

During normal mode with failure leading to the deactivation of the gate drivers (charge pump undervoltage, VS undervoltage and overvoltage, thermal shutdown) or in fail safe mode,  $R_{GGND}$  are activated, independently from the setting of **BD\_PASS**.

### Gate driver power down

The gate driver is deactivated in normal mode with **BD\_PASS** set to 1 and all HBxMODE[1:0]=00 or 11. The current consumption of the VS input is reduced to  $I_{S\_BD\_PASS}$  and  $R_{GGND}$  are activated.

### 6.5 Bridge driver in passive mode

The bridge driver is in passive mode:

- If **BD\_PASS** = 1 in normal mode and all HBxMODE[1:0]=00<sub>B</sub> or 11<sub>B</sub>.
- In sleep mode (EN = Low).
- If  $V_{DD} < V_{DDPOFFR}$ .

All MOSFETs are in passive discharge (refer to **Passive discharge**):

- in normal mode
- in sleep mode as long as  $V_S > V_{SLEEP\_SET}$
- if  $V_{DD} < V_{DDPOFFR}$  as long as  $V_S > V_{SOVPASSOFF}$

Note that after a recovery of a  $V_S$  drops below  $V_{SLEEP\_SET}$  in sleep mode or when  $V_{DD} < V_{DDPOFFR}$ , LS1-LS4 are activated if  $V_S > V_{SOVPASSOFF}$  (overvoltage brake)

## Floating gate drivers

### 6.6 Electrical characteristics gate driver

The electrical characteristics related to the gate driver are valid for  $V_{CP} > V_S + 8.5 \text{ V}$ .

**Table 15 Electrical characteristics: gate drivers**

$V_S = 6.0 \text{ V}$  to  $18 \text{ V}$  if  $V_{SOVTH} = 0$ ,  $V_S = 6.0 \text{ V}$  to  $28 \text{ V}$  if  $V_{SOVTH} = 1$ ;  $V_{DD} = 3.0 \text{ V}$  to  $5.5 \text{ V}$ ,  $T_j = -40^\circ\text{C}$  to  $150^\circ\text{C}$   
 $V_{CP} > V_S + 8.5 \text{ V}$ , all voltages with respect to ground. Positive current flowing into pin except for  $I_{GLx}$  and  $I_{GHx}$  (unless otherwise specified).

Parameter	Symbol	Values			Unit	Note or Test Condition	Number

1) Not subject to production test, specified by design.

2)  $ICHGx[4:0] = 11111_B$  (100 mA typ.)

## **7 Protections and diagnostics**

### **7.1 Reverse polarity protection**

The output of the charge pump (CP pin) can be used to supply an external n-channel MOSFET, building an active reverse polarity protection. Refer to [Figure 50](#).

### **7.2 Safe switch (optional)**

The output of the charge pump (CP pin) can be used to supply an optional external n-channel MOSFET, operating as safe switch. The safe switch can be actively turned off for example by the microcontroller or a safety logic, in order to disconnect the MOSFET supply, independently from the TLE92108-231QX. Refer to [Figure 50](#).

### **7.3 Drain-source voltage monitoring with bridge driver in active mode**

When EN = High and **BD\_PASS** = 0 (bridge driver in active mode), voltage comparators monitor the activated MOSFETs to protect the high-side MOSFETs and low-side MOSFETs against a short circuit respectively to ground and to the battery during ON-state.

If a Drain-Source overvoltage is detected, the corresponding half-bridge is latched off.

If HBxD = 0, x = 1..8 (**VDS1** and **VDS2**): The half-bridge x is latched off if the voltage difference between DH and VSHx exceeds the threshold voltage configured by **VDS1**, and **VDS2** (see [Table 16](#)).

If HBxD = 1, x = 1..8 (see **VDS1** and **VDS2**): The half-bridge x is latched off if the voltage difference between CSIN1 and VSHx exceeds the threshold voltage configured by **VDS1**, and **VDS2** (see [Table 16](#)).

Short circuits of low-side MOSFETs to VS are detected by monitoring the voltage difference between VSHx and SL (see [Table 16](#)).

**Table 16 Drain-Source overvoltage threshold, EN = High, **BD\_PASS** = 0**

<b>HBxVDSTH<sup>1)</sup>[2:0]</b>	<b>Drain-Source overvoltage threshold for HSx and LSx<sup>1)</sup> (typical)</b>
000 <sub>B</sub>	150 mV
001 <sub>B</sub>	200 mV (default)
010 <sub>B</sub>	250 mV
011 <sub>B</sub>	300 mV
100 <sub>B</sub>	400 mV
101 <sub>B</sub>	500 mV
110 <sub>B</sub>	600 mV
111 <sub>B</sub>	2 V

1) x = 1 ... 8.

**Attention:** *HBxVDSTH[2:0] = 111<sub>B</sub> (2 V threshold) is dedicated for the diagnostic in off-state. It is highly recommended to select another drain-source overvoltage threshold once the routine of the diagnostic in off-state has been performed to avoid additional current consumption from VS and from the charge pump.*

## Protections and diagnostics

The device reports a Drain-Source overvoltage error if both conditions are met:

- After expiration of the blank time.
- If the Drain-Source voltage monitoring exceeds the configured threshold for a duration longer than the configured filter time (refer to [Table 17](#) and [GENCTRL2](#) TFVDS bits).

*Note:* Exception with **static activated** MOSFETs when the short circuit is applied **before the expiration of the blank time**: the MOSFETs are turned off after the **blank time + 2 x t<sub>FVDS</sub>**

**Table 17 Drain-Source overvoltage filter time**

TFVDS[1:0]	Drain-Source overvoltage filter time (typical)
00 <sub>B</sub>	0.5 μs (default)
01 <sub>B</sub>	1 μs
10 <sub>B</sub>	2 μs
11 <sub>B</sub>	3 μs

If a short circuit is detected by the Drain-Source voltage monitoring:

- The impacted half-bridge is latched off.
  - The discharge current is according to the settings of [ST\\_ICHG](#), as if the MOSFET was previously statically activated.
- The corresponding bit in the status register [DSOV](#) is set.
- The VDSE in Global Status Register [Global status byte](#) is set.

If a Drain-Source overvoltage is detected for one of the MOSFETs, then the status register [DSOV](#) must be cleared in order to re-enable the faulty half-bridge.

## 7.4 Cross-current protection and drain-source overvoltage blank time

All gate drivers feature a cross-current protection time and a Drain-Source overvoltage blank times.

The cross-current protection avoids the simultaneous activation of the high-side and the low-side MOSFETs of the same half-bridge.

During the blank time, the drain-source overvoltage detection is disabled, to avoid a wrong fault detection during the activation phase of a MOSFET.

### Notes

1. The setting of the cross-current protection and of the blank times may be changed by the microcontroller only if all PWMx\_EN bits are reset, x = 1 ... 3.
2. Changing the Drain-Source overvoltage of a half-bridge x (HBx) in on-state (HBxMODE[1:0]=(0,1) or (1,0)) may result in a wrong VDS overvoltage detection on HBx. Therefore it is highly recommended to change this threshold when HBxMODE[1:0]=(0,0) or (1,1).

### 7.4.1 Cross-current protection

Four pairs of cross-current protection and blank times ((tCCPx, tBLANKx), x = 1...4) can be mapped to each half-bridge with the control register [CCP\\_BLK1](#).

The cross-current protection time of the active MOSFET of the FW MOSFETs are set independently.

## Protections and diagnostics

- The cross-current protection times of the active MOSFETs are configured by the control bits TCCPx\_ACT (**CCP\_BLK2\_ACT**, **PWM\_ICHGMAX\_CCP\_BLK3\_ACT**) and **CCP\_BLK1**
- The cross-current protection times of the free-wheeling MOSFETs are configured by the control bits TCCPx\_FW (**CCP\_BLK2\_FW**, **PWM\_ICHGMAX\_CCP\_BLK3\_FW**) and **CCP\_BLK1**

**Table 18 Cross-current protection time**

TCCPx_ACT[2:0], TCCPx_FW[2:0], x = 1...4	Cross-current protection time tCCPx_ACT/tCCPx_FW, x = 1...4 (typical)
000 <sub>B</sub>	375 ns
001 <sub>B</sub>	625 ns
010 <sub>B</sub>	1 µs
011 <sub>B</sub>	1.5 µs
100 <sub>B</sub>	2 µs (default)
101 <sub>B</sub>	3 µs
110 <sub>B</sub>	4 µs
111 <sub>B</sub>	16 µs <sup>1)</sup>

1) When applying a cross-current protection time of 16 µs to a half-bridge, the max. drive current used for this half-bridge must be set below 30 mA to avoid an overheating of the gate driver.

### 7.4.2 Drain-source overvoltage blank time in bridge driver active mode

A configurable blank time (refer to **Table 19**) for the Drain-Source monitoring is applied at the turn-on of the MOSFETs. During the blank time, a Drain-Source overvoltage error is masked.

The blank time of the active MOSFET of the FW MOSFETs are set independently:

- The blank times of the active MOSFETs are configured by the control bits TBLANKx\_ACT (**CCP\_BLK2\_ACT**, **PWM\_ICHGMAX\_CCP\_BLK3\_ACT**) and **CCP\_BLK1**
- The blank times of the free-wheeling MOSFETs are configured by the control bits TBLANKx\_FW (**CCP\_BLK2\_FW**, **PWM\_ICHGMAX\_CCP\_BLK3\_FW**) and **CCP\_BLK1**

### Half-bridges in PWM mode

If the detection of the generator mode is disabled (**EN\_GEN\_CHECK** = 0):

- The blank time of the PWM MOSFET starts at the expiration of the cross-current protection time of the FW MOSFET (tHBxCCP FW). Refer to **Figure 33**.
- The blank time of the FW MOSFET starts after expiration of the cross-current protection time at turn-off of the PWM MOSFET (tHBxCCP Active). Refer to **Figure 33**.

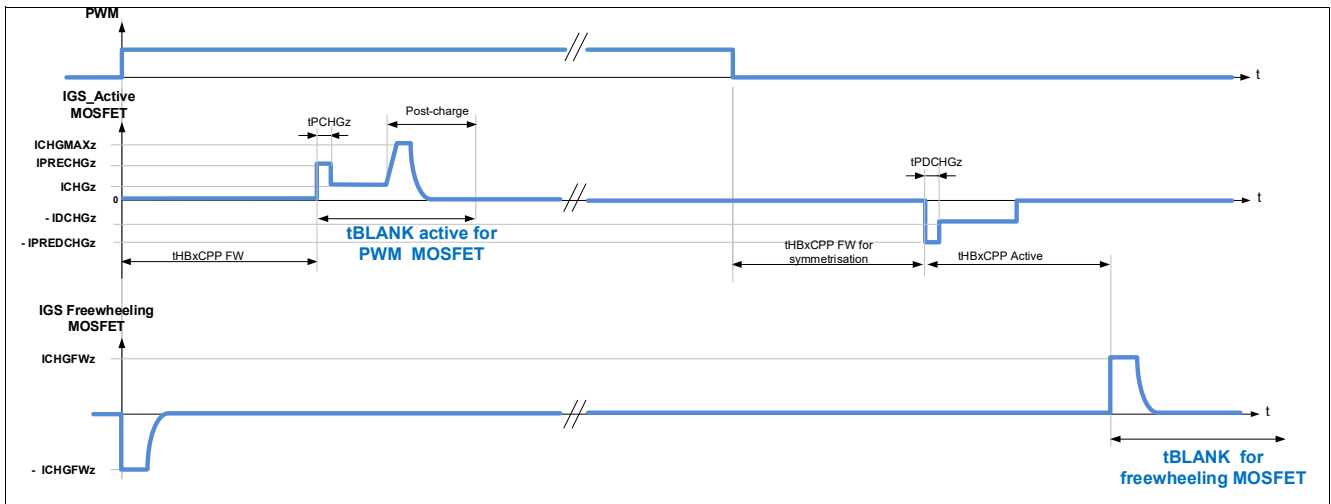

## Protections and diagnostics

**Figure 33** Blank time for half-bridges in PWM operation, detection of generator mode disabled ( $EN\_GEN\_CHECK = 0$ )

If the detection of the generator mode is enabled ( $EN\_GEN\_CHECK = 1$ ):

- The blank time of the Active MOSFET starts at the expiration of the cross-current protection time of the FW MOSFET ( $t_{HBxCPP}$  FW). Refer to [Figure 34](#) and [Figure 35](#).
- The blank time of the FW MOSFET starts after expiration of the cross-current protection time at turn-off of the Active MOSFET ( $t_{HBxCPP}$  Active). Refer to [Figure 34](#) and [Figure 35](#).

**Figure 34** Blank time for half-bridges in PWM operation, detection of generator mode enabled ( $EN\_GEN\_CHECK = 1$ ), motor operating as load

## Protections and diagnostics

**Figure 35** Blank time for half-bridges in PWM operation, detection of generator mode enabled (EN\_GEN\_CHECK = 1), motor operating as generator

For statically activated half-bridges, the blank time starts:

- Case 1: At expiration of the active cross-current protection ([Figure 7](#)), if the opposite MOSFET was previously activated.
- Case 2: Right after the decoding of the SPI command to turn on a MOSFET, if the half-bridge was in high impedance ([Figure 8](#)).

The blank times can be configured with the control registers **CCP\_BLK2\_ACT** and **PWM\_ICHGMAX\_CCP\_BLK3\_ACT** for the active MOSFETs and **CCP\_BLK2\_FW** and **PWM\_ICHGMAX\_CCP\_BLK3\_FW** for the freewheeling MOSFETs.

## Protections and diagnostics

**Table 19 Drain-source overvoltage blank time**

TBLANKx[2:0], x = 1...4	Drain-Source overvoltage blank time tBLANKx, x = 1...4 (typical)
000 <sub>B</sub>	625 ns
001 <sub>B</sub>	1 μs
010 <sub>B</sub>	1.25 μs
011 <sub>B</sub>	1.5 μs
100 <sub>B</sub>	2 μs (default)
101 <sub>B</sub>	3 μs
110 <sub>B</sub>	4 μs
111 <sub>B</sub>	16 μs <sup>1)</sup>

1) When applying a blank time of 16 μs to a half-bridge, the max. drive current used for this half-bridge must be set below 30 mA, to avoid an overheating of the gate driver.

**Note:** The blank time is implemented at every new activation of a MOSFET, including a recovery from VS undervoltage, VS overvoltage.

### 7.4.3 Mapping of cross-current protection and blank times

One of the pairs of cross-current protection and blank times are mapped to each half-bridge according to [Table 20](#), by configuring the control register [CCP\\_BLK1](#).

**Table 20 Mapping of tCCP and tBLANK to the half-bridges**

HBxCCPBLK[1:0], x=1..8	tCCP and tBLANK applied to HBx
00 <sub>B</sub>	(tCCP1,tBLANK1) are mapped to HBx <sup>1)</sup>
01 <sub>B</sub>	(tCCP2,tBLANK2) are mapped to HBx
10 <sub>B</sub>	(tCCP3,tBLANK3) are mapped to HBx
11 <sub>B</sub>	(tCCP4,tBLANK4) are mapped to HBx

1) Example: (tHBxCCP, tHBxBLANK) = (tCCP1, tBLANK1), x = 1 ... 4.

### 7.5 OFF-state diagnostic

In order to support the off-state diagnostic, the gate driver of each MOSFET provides pull-up (450 μA typ.) and a pull-down currents (1250 μA typ.) at the SHx pins when the driver driver is active ([BD\\_PASS](#) = 0). Under these conditions, the pull-up current sources are active.

**Attention:** The off-state diagnostic is possible only when the bridge driver is active ([BD\\_PASS](#)=0) and the corresponding half-bridge is off ([HBxMODE](#) = 00b or 11b).

The pull-down current of each gate driver are activated by the control bits HBxIDIAG ([HBIDIAG](#) register).

During the off-state diagnostic routine performed by the microcontroller, the drain-source overvoltage threshold of the relevant half-bridges must be set to 2 V nominal. Refer to [Table 16](#). Once the routine is finished, it is highly recommended to decrease the drain-source overvoltage threshold to a lower value, avoiding additional current consumption from the VS input.

The following failures can be detected:

### **Protections and diagnostics**

- MOSFET short circuit to GND.
- MOSFET short circuit the battery.
- Open load (disconnected motor).

The status of the output voltages  $VOUT_x$ , with  $x = 1 \dots 8$ , can be read back with status bit  $HBxVOUT$  (register **HBVOUT\_PWMERR**) when the corresponding half-bridge is in off-state ( $HBxMODE[1:0] = 00$  or  $11$ ).

*Note:*  $HBxVOUT = 0$  if the half-bridge  $x$  is not in off-state ( $HBxMODE[1:0] = (0,1)$  or  $(1,0)$ ).

Refer to **Application information, Chapter 10** for off-state diagnostic when the shunt resistor is in the motor phase.

## **7.6 Temperature monitoring**

Temperature sensors are integrated in the device. The temperature monitoring circuit compares the measured temperature to the warning and shutdown thresholds.

### **Temperature warning**

If the temperature sensor reaches  $T_{jw}$ , then **TW** is set (see **GENSTAT**). This bit is latched and reset by clearing **GENSTAT** if the thermal warning condition has disappeared. The outputs stages however remain activated. Refer to **Figure 36**.

### **Temperature shutdown**

If the temperature sensor reaches  $T_{jSD}$  **all gate drivers are latched off, the charge pump is deactivated**; the SUPE bit (Supply Error bit, see **Global status byte**), **TSD** (Thermal Shutdown bit) and **CPUV** (Charge Pump Undervoltage) are set (see **GENSTAT**). All outputs remain deactivated until the temperature shutdown condition has disappeared and **GENSTAT** is cleared. See **Figure 36**.

The discharge current is according to the settings of **ST\_ICHG**, as if the MOSFET was previously statically activated.

To resume normal functionality of the gate drivers (in the event the overtemperature condition disappears, or to verify if the failure still exists) the microcontroller shall clear **GENSTAT**.

**Figure 36 Overtemperature behavior**

## Protections and diagnostics

### 7.7 $V_S$ overvoltage and undervoltage shutdown

The power supply rails  $V_S$  and  $V_{DD}$  are monitored for supply fluctuations. The  $V_S$  supply is monitored for under- and over-voltage conditions whereas the  $V_{DD}$  supply is monitored for under-voltage conditions.

#### 7.7.1 $V_S$ undervoltage

If  $V_S$  drops below  $V_{SUV\ OFF}$ , then all external MOSFETs are latched off, however, the logic information remains intact and uncorrupted provided that  $V_{DD} > V_{DD\ POR}$ .

SUPE (Supply Error bit, see [Global status byte](#)), **VSUV** and **CPUV** bits (see [GENSTAT](#)), are set and latched.

The **VSUV** bit is reset by clearing [GENSTAT](#) to re-enable the MOSFETs.

The **VSUV** bit is reset if the following conditions are fulfilled:

- $V_S > V_{SUV\ ON}$  (See [Figure 37](#)).
- The TLE92108-231QX receives a clear command to [GENSTAT](#).

#### 7.7.2 $V_S$ overvoltage with bridge driver in active mode

If  $V_S$  rises above the switch-off voltage ( $V_{SOV\ OFF1}$  if  $V_{SOVTH} = 0$ ,  $V_{SOV\ OFF2}$  if  $V_{SOVTH} = 1$ ) all external MOSFETs are latched off, and the charge pump is deactivated. SUPE bit (see [Global status byte](#)), **VSOV** bit ( $V_S$  over-voltage bit, see [GENSTAT](#)), and CPUV bit are set and latched. If  $V_S$  decreases below  $V_{SOV\ ON}$ , then the charge pump is reactivated automatically. The **VSOV** bit must be reset to re-enable the MOSFETs.

The **VSOV** bit is reset if the following conditions are fulfilled:

- $V_S < V_{SOV\ ON}$  (See [Figure 37](#)).
- The TLE92108-231QX receives a clear command to [GENSTAT](#).

The discharge current is according to the settings of [ST\\_ICHG](#), as if the MOSFET was previously statically activated.

**Figure 37 Output behavior during Over- and Undervoltage  $V_s$  condition**

### 7.7.3 $V_{DD}$ undervoltage

If the  $V_{DD}$  logic supply decreases below the undervoltage threshold,  $V_{DD\ POffR}$ , the SPI interface shall no longer be functional. The digital block will be reset and the gate drivers are switched off. The undervoltage reset is released once  $V_{DD}$  voltage is above the undervoltage threshold,  $V_{DD\ POR}$ .

### 7.7.4 Charge pump undervoltage

The voltage of the charge pump output (VCP) is monitored in order to ensure a correct control of the external MOSFETs.

If VCP falls below the configured charge pump undervoltage threshold:

- The external MOSFETs are actively discharged for the duration  $t_{HBxCCP}$  with the current  $I_{CHGSTx}$ , then the gate drivers are turned off.
- **CPUV** (**GENSTAT**), SUPE bits (**Global status byte**) and the Global Error Flag (**Chapter 8.2**) are set and latched.

The **CPUV** and SUPE bits are reset and the normal operation is resumed if **GENSTAT** is cleared, and  $VCP > V_{CPUV}$ .<sup>1)</sup>

1) Recovering from VS under/overvoltage and thermal shutdown, CPUV bit can be cleared only after 64  $\mu$ s

## Protections and diagnostics

### Notes

1. A charge pump undervoltage event is reported after a power-on reset, when the charge time of the capacitor connected to VCP exceeds  $t_{CPUV}$ .
2. The charge pump is deactivated after a VS undervoltage, a VS overvoltage and a thermal shutdown, causing a charge pump undervoltage condition. Consequently **CPUV** and **SUPE** bits are set together with **VSOV**, **VSUV** or **TSD** bits (see **GENSTAT**).

### 7.8 Switching parameters of MOSFETs in PWM mode

The effective switching parameters of the active MOSFETs (**EN\_GEN\_CHECK** =1) or of the PWM MOSFET (**EN\_GEN\_CHECK** =0) can be read out with dedicated status registers:

- The turn-on and turn off delays, noted tDON and tDOFF, are reported by the status register **EFF\_TDON\_OFF1**, **EFF\_TDON\_OFF2**, **EFF\_TDON\_OFF3**.
- The rise and fall times, noted tRISE and tFALL, are reported by the status register **TRISE\_FALL1**, **TRISE\_FALL2**, **TRISE\_FALL3**.

Refer to **Chapter 6.3** for the definition of tDON, tDOFF, tRISE and tFALL.

If tHBxBLANK active has elapsed in motor mode, before the measurement of the effective tDON, the device reports an effective tDON corresponding to tHBxBLANK active.

If tHBxCCP active has elapsed while **EN\_GEN\_CHECK** =0<sup>1)</sup>, before the measurement of the effective tDOFF, the device reports an effective tDOFF corresponding to tHBxCCP active.

### 7.9 Timeout watchdog

An integrated timeout watchdog supervises the integrity of the communication with the microcontroller.

The watchdog period is programmable by the **WDPER** bit (refer to **GENCTRL1**).

After a Power-On Reset, the watchdog timer starts and the microcontroller must invert the logic value of the **WDTRIG** bit of the control register **GENCTRL1**. The default value of **WDTRIG** is 0. A correct trigger of the watchdog immediately resets the watchdog counter and starts the next cycle.

A watchdog failure is reported by the device if:

- The watchdog trigger bit is not served within the watchdog period (watchdog timeout event). See **Figure 38**<sup>2)</sup>.
- The microcontroller writes the **WDTRIG** bit with the same value. In other words, if the **WDTRIG** value is 0 and the microcontroller re-writes **WDTRIG** to 0, or the **WDTRIG** is 1, and the microcontroller re-writes **WDTRIG** to 1, then a watchdog error is reported.

If a watchdog failure is detected, then the FS bit (see Global Status Byte) is set and latched, and the control registers are frozen to their default values. Consequently all external MOSFETs are actively turned off.

In order to resume normal operation, the microcontroller must: 1. clear **GENSTAT**. 2. Set **WDTRIG** to 1 within the watchdog period, 3. Set **WDTRIG** to 0 within the watchdog period<sup>3)</sup>.

1) If **EN\_GEN\_CHECK**= 1 and tDOFF cannot be measured until the expiration of tHBxCCP, then the device considers that the motor operate as generator  
2) WDMON[1:0] (**GENSTAT**) is not reset after a WD timeout when the WD period is configured to 50 ms  
3) The exit sequence must be strictly followed to leave fail safe mode. If a SPI frame not belonging to the sequence is added (incl. a read command), then the device stays in fail safe mode and the microcontroller must restart the complete sequence to enter normal mode.

## Protections and diagnostics

The watchdog period is configurable by SPI to  $T_{WDPER1}$  or  $T_{WDPER2}$  (refer to **WDPER**).

### Monitoring the watchdog timer

The status bits **WDMON**[1:0] report the relative position of the watchdog timer to the watchdog period. Refer to **Table 21** and **Figure 38**. This allows the detection of a potential latent failure associated to the watchdog timer: the microcontroller can indeed verify that the watchdog timer is running.

**Table 21** Monitoring of the watchdog timer

<b>WDMON</b> [1:0]	<b>Position of the watchdog timer</b>
00 <sub>B</sub>	watchdog timer is between [0%, 25%[ of the watchdog period
01 <sub>B</sub>	watchdog timer is between [25%, 50%[ of the watchdog period
10 <sub>B</sub>	watchdog timer is between [50%, 75%[ of the watchdog period
11 <sub>B</sub>	watchdog timer is between [75%, 100%[ of the watchdog period

**Figure 38** Example of watchdog monitoring and watchdog timeout

### Disabling the watchdog

The watchdog is enabled by default.

It is disabled only if the following SPI sequence is sent:

- First frame: Set **UNLOCK** bit to '1' (**GENCTRL1**). Note: UNLOCK is automatically reset to '0' at the end of the following frame.
- Following frame: Set **WDDIS** bit to '1' (**GENCTRL2**).

The watchdog is directly re-enabled by setting **WDDIS** to '0'.

## Protections and diagnostics

### 7.10 Current sense amplifier

Two current sense amplifiers allow to monitor the motor currents. The differential input stage measures the voltage drop across an external shunt resistor.

The input common mode range allows current sensing in high-side, in low-side configuration or in the motor phase.

#### 7.10.1 Unidirectional and bidirectional operation

The current sense amplifiers (CSA) can work either as unidirectional or bi-directional CSA. See [CSD1](#) and [CSD2](#).

##### Unidirectional operation CSDx = 0

In unidirectional operation, the CSAx, x = 1 or 2, is optimized to measure the current flowing through the external shunt resistor when  $V_{CSIPx} \geq V_{CSINx}$ .

$V_{CSOx} = V_{REF\ Unidir} + (V_{CSIPx} - V_{CSINx} + V_{os}) \times G_{DIFF}$ , provided that  $V_{CSOx}$  is in the linear range<sup>1) 2)</sup>.

##### Bidirectional operation CSDx = 1

In bidirectional operation, the CSAx, x = 1 or 2, measures the current flowing through the external shunt resistor in both directions:  $V_{CSIPx} \geq V_{CSINx}$  or  $V_{CSIPx} \leq V_{CSINx}$ .

The output CSOx works at half-scale range:  $V_{CSOx} = V_{REF\ Bidir} + (V_{CSIPx} - V_{CSINx} + V_{os}) \times G_{DIFF}$  provided that  $V_{CSOx}$  is in the linear range<sup>2)</sup>.

When the current sense amplifiers are deactivated (VS undervoltage, VS overvoltage, CP undervoltage or Overtemperature, or CSAx\_OFF = 1), CSOx is pulled Low (between GND to 150 mV)

#### 7.10.2 Gain configuration

The gain of the current sense amplifier is configurable by the configuration bits CSAGx bits. Refer to [Table 22](#) and [GENCTRL1](#).

**Table 22 Configuration of the current sense amplifier gain**

CSAGx[1:0]	Typical current sense amplifier gain $G_{DIFF}$
00 <sub>B</sub>	10 V/V
01 <sub>B</sub>	20 V/V
10 <sub>B</sub>	40 V/V
11 <sub>B</sub>	80 V/V

#### 7.10.3 High-side and low-side setting

The CSA can be used either in high-side configuration or in low-side configuration within the specified common mode range.

The control bits CSA1L and CSA2L ([HBIDIAG](#)) optimize the VDD current consumption by informing the device about the common mode voltage of the CSA inputs:

- CSAxL must be set to 0 if the shunt is in low-side configuration (i.e. connected to GND or to an output with an activated low-side).

1) Valid if  $0.5\text{ V} \leq V_{CSOx} \leq V_{DD} - 0.5\text{ V}$ .

2)  $V_{CSOx}$  is clamped between VDD and GND.

## Protections and diagnostics

- CSAxL must be set to 1 if the shunt is in high-side configuration (i.e. connected to VS or to an output with an activated high-side).

### Notes

- A proper information from the CSA output is not ensured if the external shunt resistor is in high-side configuration while its CSAxL bit is set to 0.
- The external shunt resistor may be in low-side configuration while its CSAxL bit is set to 1. The current consumption from VDD is however higher than if CSAxL is set to 0.

### 7.10.4 Overcurrent detection

A comparator at CSOx detects overcurrent conditions. The overcurrent threshold is configurable with the OCTHx bits. Refer to [Table 23](#) for unidirectional operation and [Table 24](#) for bidirectional operation.

**Table 23 Overcurrent detection thresholds in unidirectional operation (CSDx = 0)**

OCTHx[1:0]	Typical Overcurrent Detection Threshold
00 <sub>B</sub>	$V_{CSOx} > V_{DD/2}$
01 <sub>B</sub>	$V_{CSOx} > V_{DD/2} + V_{DD}/10$
10 <sub>B</sub>	$V_{CSOx} > V_{DD/2} + 2 \times V_{DD}/10$
11 <sub>B</sub>	$V_{CSOx} > V_{DD/2} + 3 \times V_{DD}/10$

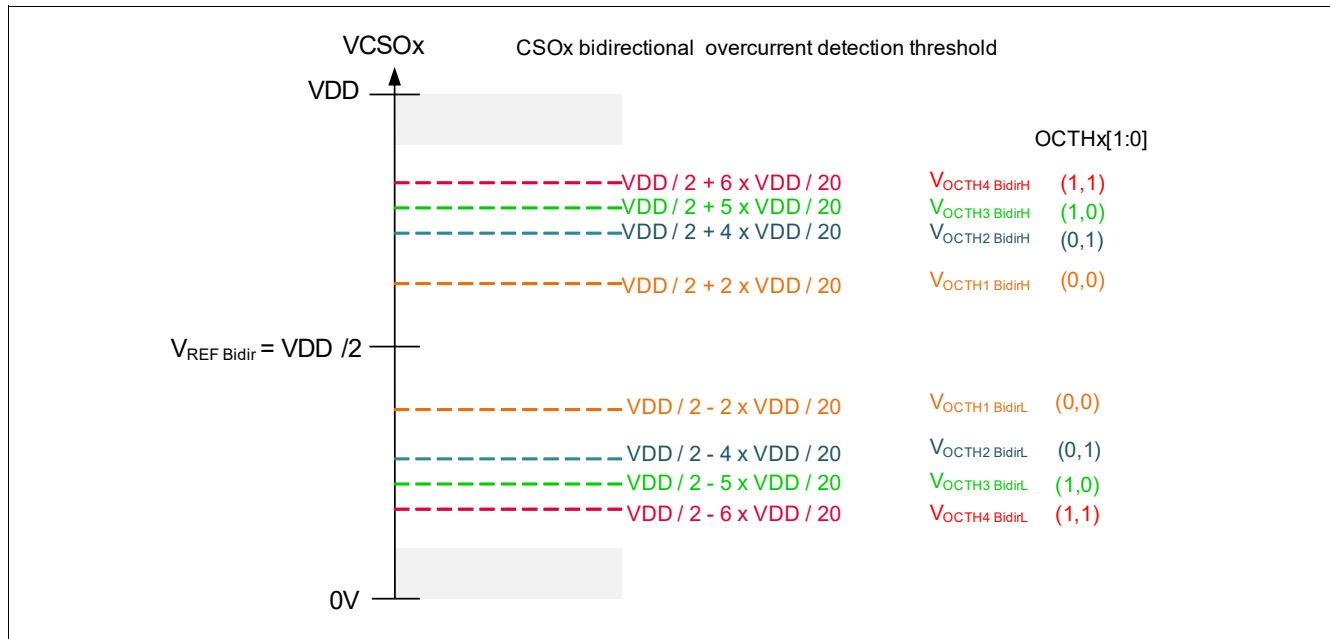

**Figure 39 Overcurrent detection thresholds in unidirectional operation (CSDx = 0)**

## Protections and diagnostics

**Table 24 Overcurrent detection thresholds in bidirectional operation (CSDx = 1)**

OCTHx[1:0]	Typical Overcurrent Detection Threshold
00 <sub>B</sub>	$V_{CSOx} > V_{DD}/2 + 2 \times V_{DD}/20$ or $V_{CSOx} < V_{DD}/2 - 2 \times V_{DD}/20$
01 <sub>B</sub>	$V_{CSOx} > V_{DD}/2 + 4 \times V_{DD}/20$ or $V_{CSOx} < V_{DD}/2 - 4 \times V_{DD}/20$
10 <sub>B</sub>	$V_{CSOx} > V_{DD}/2 + 5 \times V_{DD}/20$ or $V_{CSOx} < V_{DD}/2 - 5 \times V_{DD}/20$
11 <sub>B</sub>	$V_{CSOx} > V_{DD}/2 + 6 \times V_{DD}/20$ or $V_{CSOx} < V_{DD}/2 - 6 \times V_{DD}/20$

**Figure 40 Overcurrent detection thresholds in bidirectional operation (CSDx = 1)**

It is possible to program the device behavior when an overcurrent condition is detected:

- OCEN bit = 0 (see **GENCTRL1**): the device only reports the overcurrent event (OC, OC1 or OC2 in **GENSTAT** and Global Error Flag are set), without any change of the gate driver states
  - If the overcurrent condition is not present for more than  $t_{FOC}$ , then the overcurrent status bits are automatically cleared by the device.
- OCEN bit = 1 (see **GENCTRL1**): the device reports the overcurrent event (OC, OC1 or OC2 in **GENSTAT** and Global Error Flag are set) and turns off all MOSFETs with their static discharge current.
  - The MOSFETs can be reactivated by clearing **GENSTAT** or by resetting the OCEN bit.
  - The overcurrent status bits are reset only if the overcurrent condition is no longer present and the microcontroller clears **GENSTAT**.

The overcurrent filter time is configurable (refer to  $t_{FOC}$ ) by the control bits OCxFILT (refer to **HBIDIAG**).

$t_{FOC}$  refers to the output of the current sense amplifier. The CSO settling time (2  $\mu$ s max,  $t_{SET}$ ) and the analog propagation delay (< 1  $\mu$ s) are not taken into account by the overcurrent filter time.

### 7.10.5 CSO outputs capacitor

The capacitor directly connected to CSOx (CCSOx) must be between 10 pF and 400 pF (refer to **Chapter 10**).

## **Protections and diagnostics**

The control bit **CCSO** (see **PWM\_IDCHG\_ACT**, **PWM\_PDCHG\_INIT**) optimizes the VDD current consumption for  $CCSOx < 100 \text{ pF}$  or  $CCSOx > 100 \text{ pF}$ .

## Protections and diagnostics

### 7.11 Electrical characteristics protections and diagnostics

The specified drain-source monitoring thresholds, the overcurrent thresholds and the electrical characteristics related to the current sense amplifiers are valid for  $V_{CP} > V_S + 8\text{ V}$

**Table 25 Electrical characteristics:**

$V_S = 6.0\text{ V}$  to  $18\text{ V}$  if  $V_{SOVTH} = 0$ ,  $V_S = 6.0\text{ V}$  to  $28\text{ V}$  if  $V_{SOVTH} = 1$ ;  $V_{DD} = 3.0\text{ V}$  to  $5.5\text{ V}$ ,  $T_j = -40^\circ\text{C}$  to  $150^\circ\text{C}$

$V_{CP} > V_S + 8\text{ V}$

All voltages with respect to ground, positive current flowing into pin (unless otherwise specified)

1) Not subject to production test, specified by design.

2)  $t_{FOC}$  refers to the output of the current sense amplifier. The CSO settling time ( $2\text{ }\mu\text{s}$  max,  $t_{SET}$ ) and the analog propagation delay ( $< 1\text{ }\mu\text{s}$ ) are not taken into account by the overcurrent filter time.

## 8 Serial Peripheral Interface - SPI

The 24-bit Serial Peripheral Interface (SPI) enables the communication between the microcontroller and the TLE92108-231QX. It allows to configure and control the device, and to read out the status registers for diagnostic purpose. The MOSFET driver IC acts as a SPI-slave while the microcontroller acts as a SPI-master.

The interface has a serial data input pin (SDI) to transfer data to the device, a serial data output pin (SDO) for reading data back from the device, and a serial clock pin (SCLK) for clocking data into and out of the device. A chip select pin (CSN) enables or disables the serial interface.

The SPI frame starts with the falling edge of CSN. During the falling edge of CSN, SCLK must be low (Clock Polarity CPOL = 0). Received data on SDI are shifted in on the falling edge of SCLK. Transmitted data by SDO are shifted out on the rising edge of SCLK (Clock Phase CPHA = 1). Refer to [Figure 42](#).

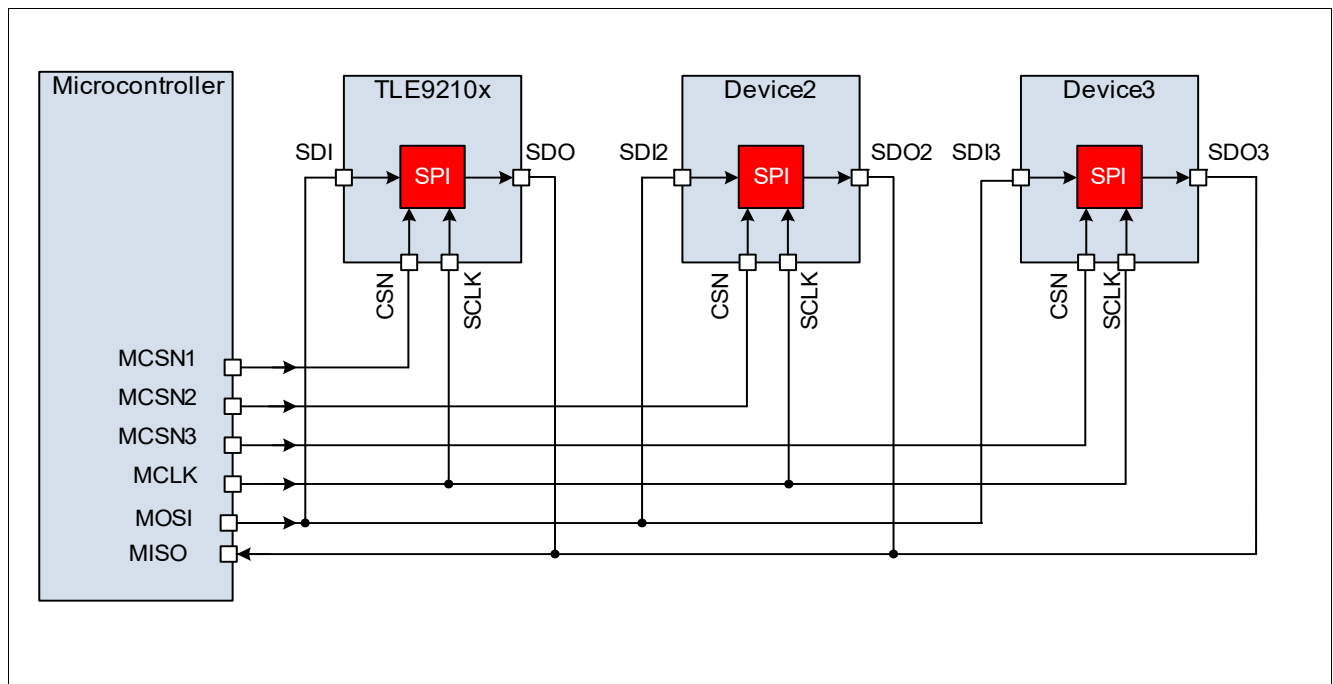

The Most Significant Bit (MSB, bit 23) is shifted in/out first.

Write and clear commands are executed at the rising edge of CSN.

The SPI protocol supports both independent slave selection and daisy chain configurations.

### 8.1 SPI protocol with independent slave selection

With individual slave selection, the microcontroller controls the CSN pin of each SPI slave individually ([Figure 41](#)).

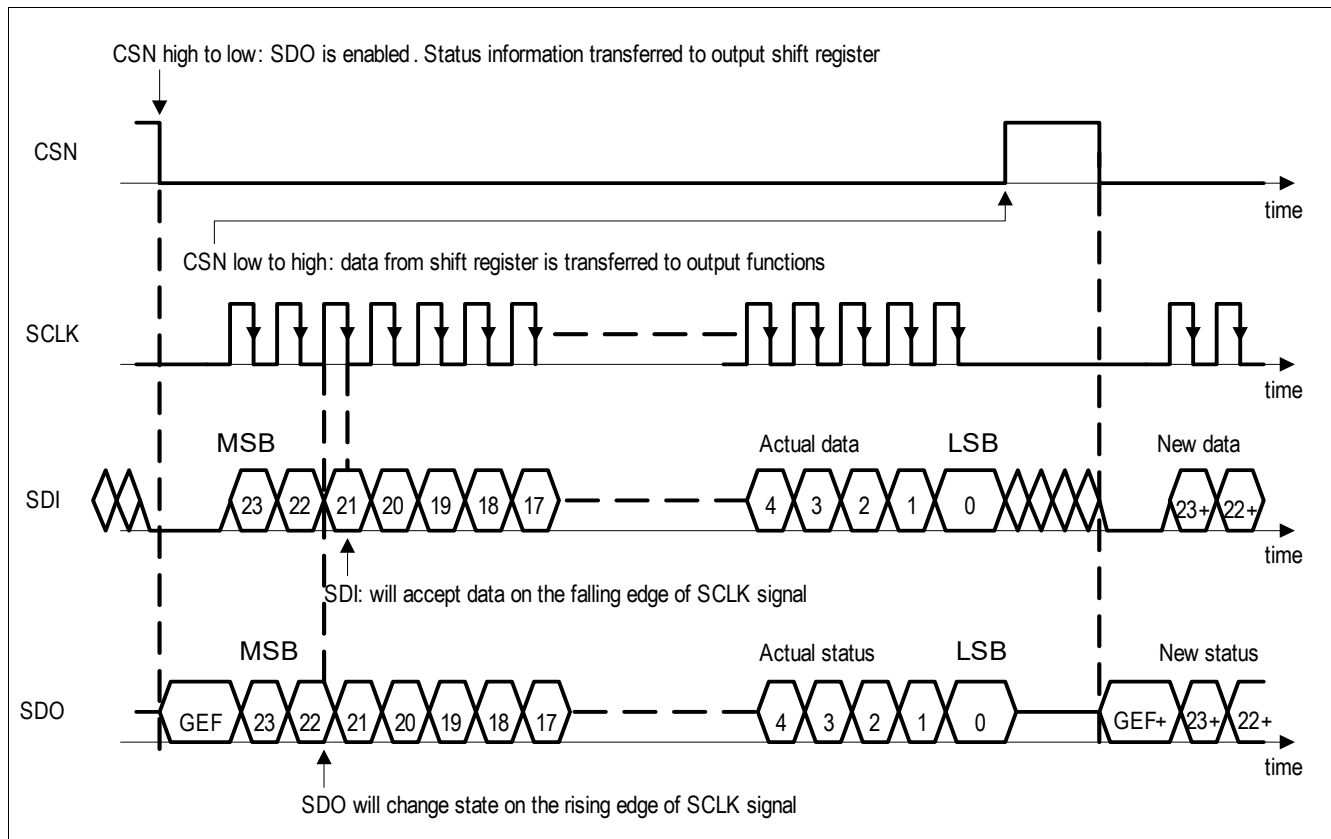

**Figure 41 Individual slave selection with three slave devices**

A SPI communication consists of 24-bit frame ([Figure 42](#)):

- SDI receives one address byte followed by two data bytes.
- SDO transmits the Global Error Flag and the Global Status Byte followed by two response bytes.

## Serial Peripheral Interface - SPI

**Figure 42 SPI Data Transfer**

### The MSB of the address byte must be set to '1'.

The address byte specifies (see [Figure 43](#)):

- the target register (A[4:0])
- the type of operation:
  - For control registers:
    - Read only: OP bit<sup>1)</sup> = '0'
    - Read and write: OP bit = '1'
  - For status registers:
    - Read only: OP bit = '0'
    - Read and clear: OP bit = '1'

**With individual slave selection, the Last Address Byte Token (LABT) must be set to '1'.**

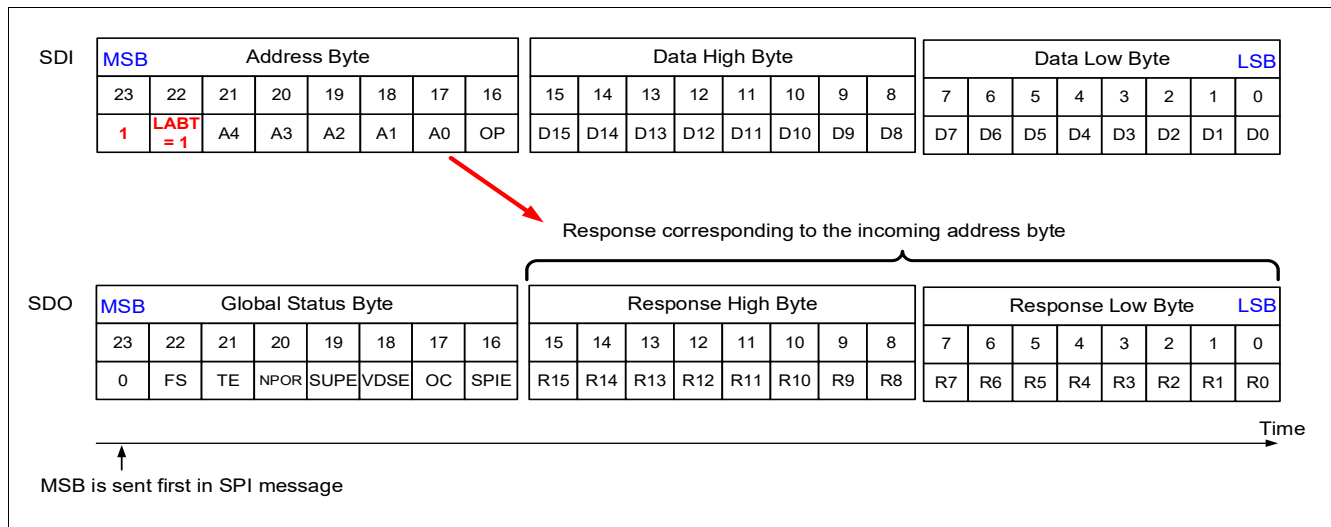

### In-frame response

The SPI protocol incorporates an in-frame response: The content of the addressed register is shifted out by SDO within the same SPI frame. This feature reduces the SPI bus load during the read out of the control or status registers.

1) OP bit is the least significant bit of the address byte, see [Figure 43](#)

## Serial Peripheral Interface - SPI

**Figure 43** In-frame response with individual slave selection

## 8.2 Global Error Flag (GEF)

The Global Error Flag (GEF) is reported on SDO between the CSN falling edge and the first SCLK rising edge. GEF is set if a fault condition is detected or if the device comes from a Power On Reset (POR). It is therefore possible to have a quick device diagnostic without any SPI clock pulse (**Figure 44**).

**Figure 44** GEF - Diagnostic with 0-clock cycle

## 8.3 Global status byte

The SDO shifts out during the first eight SCLK cycles the Global Status Byte. This register provides an overview of the device status. The following error conditions are reported in this byte:

- Fail Safe (FS bit).
- Temperature error (TE bit): logical OR combination between Thermal Warning (**TW**) and Thermal shutdown (**TSD**).
- **Negated** Power ON Reset (NPOR bit, refer to **Chapter 5.3** for reset conditions).

## Serial Peripheral Interface - SPI

- Supply Error (SUPE bit): logical OR combination between VS undervoltage shutdown (**VSUV**), VS overvoltage shutdown (**VSOV**) and charge pump undervoltage (**CPUV**).
- VDS monitoring Error (VDSE bit): logical OR combination between the bits of the **DSOV** register.
- Overcurrent (OC bit): logical OR combination between OC1 and OC2 status bits (**GENSTAT** register).
- SPI protocol Error (SPIE bit).

*Note:* The Global Error Flag is a logic OR combination of every bit of the Global Status Byte and of TDREGx:  $GEF = (FS) \text{ OR } (TE) \text{ OR } (\text{NOT}(\text{NPOR})) \text{ OR } (SUPE) \text{ OR } (VDSE) \text{ OR } (OC) \text{ OR } (SPIE) \text{ OR } (\text{NOT}(\text{TDREGx}) \text{ AND } (PWMx\_EN = 1) \text{ AND } (\text{NOT}(\text{MSKTDREG})))$ ,  $x = 1 \dots 3$ .

The following table shows how failures are reported in the Global Status Byte and the error Flag:

**Table 26 Failure reported in the global status byte and global error flag**

Type of Error	Failure reported in the Global Status Byte	Global Error Flag
Fail safe	FS = 1	1
Thermal error	TE = 1	1
Power ON reset	<b>NPOR = 0</b>	1
Supply error	SUPE = 1	1
Drain source voltage monitoring	VDSE = 1	1
Overcurrent	OC = 1	1
SPI protocol error	SPIE = 1	1
TDREGx, $x = 1 \dots 3$ <sup>1)</sup> (see <b>GENSTAT</b> )	-	1 if MSKTDREG = 0 <sup>2)</sup> 0 if MSKTDREG = 1 <sup>2)</sup>
No error and no power ON reset	SPIE = 0 OC = 0 VDSE = 0 SUPE = 0 <b>NPOR = 1</b> TE = 0 FS = 0  TDREGx = 0,	0

1) See status register **GENSTAT**.

2) See control register **GENCTRL2**.

*Note:* The default value (after Power ON Reset) of NPOR is 0, therefore the default value of GEF is 1.

In fail safe mode, the control registers are frozen to their default value, with the exception of the WDTRIG bit (refer to **Chapter 5.2.3**). Any write access (except for WDTRIG bit) in fail safe mode will be discarded and the SPIE bit will set.

## **8.4 SPI error detection**

The SPI incorporates an error flag in the Global Status Byte (SPIE) to supervise and preserve the data integrity. If an SPI protocol error is detected during a given frame, the SPIE bit is set in the next SPI communication.

The SPIE bit is set in the following error conditions:

- The number of SCLK clock pulses received when CSN is Low is (protocol error):
  - not zero
  - or less than 24
  - or more than 24 but not a multiple of 8
- The microcontroller sends an SPI command to an unused address (protocol error).
- A clock polarity error is detected (see **Figure 45** Case 2 and Case 3): the incoming clock signal was High during CSN rising or falling edges (protocol error).
- No address byte or no last address byte are detected (protocol error).
- In daisy chain: the microcontroller does not send in sequence the first address byte until the last address byte (i.e. with gaps between two address bytes). In this case, the SDO signal is set to '0' during the remaining part of the SPI frame<sup>1)</sup>, in order to prevent other devices from executing wrong commands (protocol error).
- A clear command to address 0x1F (Device ID register, Offset address = 0x1F).
- The same half-bridge is allocated to several activated PWM channels.
- Any write or clear command received in fail safe mode and not belonging to the exit sequence (refer to **Chapter 5.2.3**).

*Note: SPI commands to activate a half-bridge mapped to several PWM channels are ignored.*

In fail safe mode, the control registers may not be accessed, except for writing WDTRIG. An invalid write command in this mode sets the SPIE bit.

For a correct SPI communication:

- SCLK must be Low for a minimum  $t_{BEF}$  before CSN falling edge and  $t_{lead}$  after CSN falling edge.
- SCLK must be Low for a minimum  $t_{lag}$  before CSN rising edge and  $t_{BEH}$  after CSN rising edge.

1) Provided that the SPI frame has a correct polarity

**Figure 45 Clock polarity error**

The reset condition of the SPIE bit depends on the cause of error:

- In normal mode:
  - The microcontroller must clear **HBVOUT\_PWMERR** if one half-bridge has been allocated to several PWM channels.
  - The microcontroller must send a correct SPI frame for the other errors reported by SPIE.
- If SPIE has been set in fail safe mode, the device must enter normal mode first.

## 8.5 Daisy chain

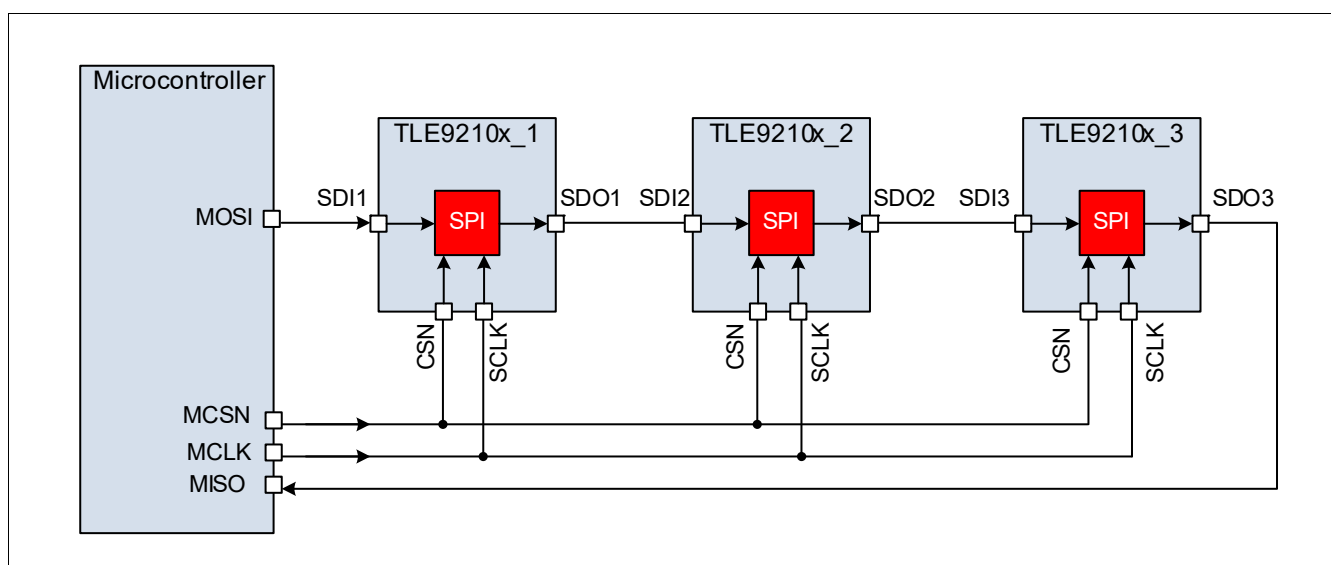

In daisy chain configuration the master output / slave input (noted MOSI) is connected to a slave SDI. The first slave SDO is connected to the next slave SDI in the chain. The SDO of the final in the chain is connected to the master input / slave output (noted MISO). In daisy chain configuration, the microcontroller MCSN is connected to all the slave CSN inputs (**Figure 46**).

## Serial Peripheral Interface - SPI

To support daisy chain configurations, the TLE92108-231QX accepts SPI frames with more than 24 bits, provided that the number of bits is a multiple of 8, and the structure of the address byte is respected.

In daisy chain, the TLE92108-231QX works as follows:

1. The TLE92108-231QX operates as a 8-bit shift register until it receives the first address byte. This first received address byte is considered by the device as its own address byte.
2. The TLE92108-231QX copies directly SDI to SDO until the last address byte is detected.
3. The TLE92108-231QX shifts out the response high byte and low byte corresponding to the address byte.
4. After the last address byte, the TLE92108-231QX operates as a 16-bit shift register until the end of the SPI frame.

**Figure 46** Daisy chain configuration with three TLE9210x devices

In daisy chain configuration (**Figure 46**), the microcontroller must send the address and data bytes in the following order (**Figure 47**):

1. The address bytes altogether are sent first:
  - Address byte 1 (for TLE9210x\_1) is sent first, followed by address byte 2 (for TLE9210x\_2), followed by address byte 3 (for TLE9210x\_3).
  - The LABT bit of the last address byte must be '1', while the LABT bit of all the other address bytes must be '0'.
2. The data bytes are sent altogether **in reverse order** once the address bytes are transmitted:
  - The data high byte for the TLE9210x\_3 is sent first followed by the data low byte for the TLE9210x\_3.
  - Then the data high byte for the TLE9210x\_2 is sent followed by the data low byte for the TLE9210x\_2.
  - Then the data high byte for the TLE9210x\_1 is sent followed by the data low byte for the TLE9210x\_1.

The Master Input / Slave Output (MISO), which is connected to SDO of the last device in the daisy chain, receives:

1. A logic OR combination of all Global Error Flags (GEF) at the beginning of the SPI frame, between CSN falling edge and the first SCLK rising edge.
2. The Global Status Byte of each TLE9210x **in reverse order**:

**Serial Peripheral Interface - SPI**

- The Global Status Byte 3 (GSB3) corresponding to the TLE9210x\_3 is received first, followed by GSB2 (corresponding to the TLE9210x\_2), and finally the GSB1 (corresponding to the TLE9210x\_1) is received.
3. The response of each TLE9210x **in reverse order**:
- The response high byte of the TLE9210x\_3 is received first followed by the response low byte of the TLE9210x\_3.
  - Then the response high byte of the TLE9210x\_2 is received followed by the response low byte of the TLE9210x\_2.
  - Then the response high byte of the TLE9210x\_1 is received followed by the response low byte of the TLE9210x\_1.

Serial Peripheral Interface - SPI

Figure 47 SPI Frame in daisy chain configuration with three TLE9210x devices

## 8.6 SPI electrical characteristics: timings

## Register specification

## 9 Register specification

### 9.1 Control registers

Table 28 Register Overview

Register Short Name	Register Long Name	Offset Address	Reset Value
<b>GENCTRL1</b>	General control register 1	0x00 and <b>REG_BANK</b> = 0 or 1	0x0026
<b>GENCTRL2</b>	General control register 2	0x01 and <b>REG_BANK</b> = 0 or 1	0x4180
<b>VDS1</b>	Drain-source monitoring HB1-4	0x02 and <b>REG_BANK</b> = 0 or 1	0x0249
<b>VDS2</b>	Drain-source monitoring HB5-8	0x03 and <b>REG_BANK</b> = 0 or 1	0x0249
<b>CCP_BLK1</b>	Cross current protection and blank times setting 1	0x04 and <b>REG_BANK</b> = 0 or 1	0x0000
<b>CCP_BLK2_ACT</b>	Cross current protection and blank times setting <b>for active MOSFETs<sup>1)</sup></b>	0x05 and <b>REG_BANK</b> = 0	0x4924
<b>CCP_BLK2_FW</b>	Cross current protection and blank times setting <b>for FW MOSFETs<sup>1)</sup></b>	0x05 and <b>REG_BANK</b> = 1	0x4924
<b>HBMODE</b>	Half-bridge mode	0x06 and <b>REG_BANK</b> = 0 or 1	0x0000
<b>PWMSET</b>	Setting of PWM channels	0x07 and <b>REG_BANK</b> = 0 or 1	0x6C60
<b>TPRECHG</b>	PWM pre-charge and pre-discharge time	0x08 and <b>REG_BANK</b> = 0 or 1	0x0000
<b>HBIDIAG</b>	Half-bridge diagnostic current control	0x09 and <b>REG_BANK</b> = 0 or 1	0xC000
<b>ST_ICHG</b>	Charge current for static half-bridges	0x0A and <b>REG_BANK</b> = 0	0x0044
<b>PWM_PCHG_INIT</b>	Precharge current initialization	0x0A and <b>REG_BANK</b> = 1	0x18C6
<b>PWM_ICHG_ACT</b>	Charge current for half-bridges in PWM ( <b>active MOSFETs<sup>1)</sup></b> )	0x0B and <b>REG_BANK</b> = 0	0x18C6
<b>PWM_ICHG_FW</b>	Charge current for half-bridges in PWM ( <b>FW MOSFETs<sup>1)</sup></b> )	0x0B and <b>REG_BANK</b> = 1	0x18C6
<b>PWM_IDCHG_ACT</b>	Discharge current of <b>active MOSFETs<sup>1)</sup></b> in PWM operation	0x0C and <b>REG_BANK</b> = 0	0x1CE7
<b>PWM_PDCHG_INIT</b>	Predischarge current initialization	0x0C and <b>REG_BANK</b> = 1	0x318C
<b>PWM_ICHGMAX_CCP_BLK3_ACT</b>	Max. pre-charge / pre-discharge currents for half-bridges in PWM <sup>2)</sup> , <b>tCCP</b> and <b>tBLANK</b> setting <b>for active MOSFETs<sup>1)</sup></b>	0x0D and <b>REG_BANK</b> = 0	0x4900
<b>PWM_ICHGMAX_CCP_BLK3_FW</b>	Max. pre-charge / pre-discharge currents for half-bridges in PWM <sup>2)</sup> , <b>tCCP</b> and <b>tBLANK</b> setting <b>for FW MOSFETs<sup>1)</sup></b>	0x0D and <b>REG_BANK</b> = 1	0x4900

## Register specification

**Table 28 Register Overview** (cont'd)

Register Short Name	Register Long Name	Offset Address	Reset Value
<b>TDON_OFF1</b>	Turn-on and turn-off delays for PWM channel1	0x0E and <b>REG_BANK</b> = 0 or 1	0x0A0A
<b>TDON_OFF2</b>	Turn-on and turn-off delays for PWM channel2	0x0F and <b>REG_BANK</b> = 0 or 1	0x0A0A
<b>TDON_OFF3</b>	Turn-on and turn-off delays for PWM channel3	0x10 and <b>REG_BANK</b> = 0 or 1	0x0A0A

- 1) Refer to **Chapter 6.3.1** for the definition of the active and the free-wheeling MOSFETs, depending on the setting of **AGC**
- 2) **ICHGMAX** is also the current applied to the Active MOSFET during post-discharge.

## Register specification

### 9.1.1 General Control Registers and Protection Settings

#### General control register 1

##### GENCTRL1

General Control Register 1 (0 0000<sub>B</sub>) Reset Value: 0000 0000 0010 0110<sub>B</sub>

## Register specification

### PWM discharge current for active MOSFETs

**Attention:** This register is accessed only if **REG\_BANK** = 0 with the corresponding offset address.

#### PWM\_IDCHG\_ACT

**PWM discharge current** (0 1100<sub>B</sub>) Reset Value: 0001 1100 1110 0111<sub>B</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCSO			IDCHG3					IDCHG2					IDCHG1		
rw			rw					rw					rw		

Field	Bits	Type	Description
CCSO	15	rw	<b>Capacitor connected to the current sense amplifier outputs</b> 0 <sub>B</sub> Capacitor connected to CSO < 100 pF (default) 1 <sub>B</sub> Capacitor connected to CSO < 400 pF
IDCHG3	14:10	rw	<b>Discharge current for PWM Channel 3 (Active MOSFET)</b> Refer to <a href="#">Table 14</a> Default: 00111 <sub>B</sub> : typ. 11.8 mA
IDCHG2	9:5	rw	<b>Discharge current for PWM Channel 2 (Active MOSFET)</b> Refer to <a href="#">Table 14</a> Default: 00111 <sub>B</sub> : typ. 11.8 mA
IDCHG1	4:0	rw	<b>Discharge current of PWM Channel 1 (Active MOSFET)</b> Refer to <a href="#">Table 14</a> Default: 00111 <sub>B</sub> : typ. 11.8 mA

## Register specification

### PWM Active MOSFET predischage current initialization

**Attention:** This register is accessed only if **REG\_BANK** = 1 with the corresponding offset address.

#### PWM\_PDCHG\_INIT

Initial PWM predischage current selection(0 1100<sub>B</sub>)Reset Value: 0011 0001 1000 1100<sub>B</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
CCSO	PDCHGINIT3					PDCHGINIT2					PDCHGINIT1				
rw	rw					rw					rw				

Field	Bits	Type	Description
<b>CCSO</b>	15	rw	<b>Capacitor connected to the current sense amplifier outputs</b> 0 <sub>B</sub> Capacitor connected to CSO < 100 pF (default) 1 <sub>B</sub> Capacitor connected to CSO < 400 pF
<b>PDCHGINIT 3</b>	14:10	rw	<b>Initial predischage current of PWM Channel 3</b> Refer to <a href="#">Table 14</a> Default: 01100 <sub>B</sub> : typ. 26.0 mA
<b>PDCHGINIT 2</b>	9:5	rw	<b>Initial predischage current of PWM Channel 2</b> Refer to <a href="#">Table 14</a> Default: 01100 <sub>B</sub> : typ. 26.0 mA
<b>PDCHGINIT 1</b>	4:0	rw	<b>Initial predischage current of PWM Channel 1</b> Refer to <a href="#">Table 14</a> Default: 01100 <sub>B</sub> : typ. 26.0 mA

## Register specification

### PWM maximum drive current selection and active tCCP4, tBLANK 3/4

**Attention:** This register is accessed with **REG\_BANK** = 0 and the offset address 0 1101<sub>B</sub>. tCCP and tBLANK are applicable to the active MOSFETs.

#### PWM\_ICHGMAX\_CCP\_BLK3\_ACT

**PWM max. drive current** (0 1101<sub>B</sub>) Reset Value: 0100 1001 0000 0000<sub>B</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved	TBLANK4_ACT			TCCP4_ACT			TBLANK3_ACT			ICHGMAX3		ICHGMAX2		ICHGMAX1	
r	rw			rw			rw			rw		rw		rw	

Field	Bits	Type	Description
Reserved	15	r	Reserved. Always read as '0'
TBLANK4_ACT	14:12	rw	<b>Blank time<sup>1)</sup> - tBLANK4 Active</b> Refer to <a href="#">Table 30</a> Default: 100 <sub>B</sub> ; typ. 2000 ns
TCCP4_ACT	11:9	rw	<b>Cross-current protection<sup>1)</sup> - tCCP4 Active</b> Refer to <a href="#">Table 29</a> Default: 100 <sub>B</sub> ; typ. 2000 ns
TBLANK3_ACT	8:6	rw	<b>Blank time<sup>1)</sup> - tBLANK3 Active</b> Refer to <a href="#">Table 30</a> Default: 100 <sub>B</sub> ; typ. 2000 ns
ICHGMAX3	5:4	rw	<b>Maximum drive current of half-bridge mapped to PWM channel 3 during the pre-charge phase and pre-discharge phases<sup>2)</sup></b> 00 <sub>B</sub> (default) charge: typ. 18.8 mA, discharge: typ. 19.7 mA 01 <sub>B</sub> charge: typ. 41mA, discharge: typ. 43 mA 10 <sub>B</sub> charge: typ. 77 mA, discharge: typ. 79 mA 11 <sub>B</sub> charge: typ. 100 mA, discharge: typ. 100 mA
ICHGMAX2	3:2	rw	<b>Maximum drive current of half-bridge mapped to PWM channel 2 during the pre-charge phase and pre-discharge phases<sup>2)</sup></b> 00 <sub>B</sub> (default) charge: typ. 18.8 mA, discharge: typ. 19.7 mA 01 <sub>B</sub> charge: typ. 41 mA, discharge: typ. 43 mA 10 <sub>B</sub> charge: typ. 77 mA, discharge: typ. 79 mA 11 <sub>B</sub> charge: typ. 100 mA, discharge: typ. 100 mA
ICHGMAX1	1:0	rw	<b>Maximum drive current of half-bridge mapped to PWM channel 1 during the pre-charge and pre-discharge phases<sup>2)</sup></b> 00 <sub>B</sub> (default) charge: typ. 18.8 mA, discharge: typ. 19.7 mA 01 <sub>B</sub> charge: typ. 41 mA, discharge: typ. 43 mA 10 <sub>B</sub> charge: typ. 77 mA, discharge: typ. 79 mA 11 <sub>B</sub> charge: typ. 100 mA, discharge: typ. 100 mA

1) Refer to [CCP\\_BLK1](#) for the mapping of (tCCPx,tBLANKx) to the half-bridges.

2) ICHGMAX is also the current applied during the post-charge of the PWM MOSFET Refer to [Table 12](#).

## Register specification

### PWM maximum drive current selection and FW tCCP4, tBLANK 3/4

**Attention:** This register is accessed with **REG\_BANK = 1** and the offset address **0 1101<sub>B</sub>**. tCCP and tBLANK are applicable to the FW MOSFETs.

#### PWM\_ICHGMAX\_CCP\_BLK3\_FW

**PWM max. drive current** (0 1101<sub>B</sub>) Reset Value: 0100 1001 0000 0000<sub>B</sub>

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

**Register specification**

Field	Bits	Type	Description
<b>HB1VOUT</b>	0	r	<b>Voltage level at SH1 when HB1MODE[1:0] = (0,0) or (1,1):</b> $0_B$ Low: $ VDH - VSH1  > V_{VDSMONTHx}^{2)}$ if HB1D = 0; $ VCSIN1 - VSH1  > V_{VDSMONTHx}$ if HB1D = 1 $1_B$ High: $ VDH - VSH1  < V_{VDSMONTHx}$ if HB1D = 0; $ VCSIN1 - VSH1  < V_{VDSMONTHx}$ if HB1D = 1  <i>Note: HB1VOUT = 0 if HB1MODE[1:0] = (0,1) or (1,0)</i>

1) The bit is reset only if one PWM channel or no PWM channel is mapped to the half-bridge (refer to **PWMSET**).

2)  $V_{VDSMONTHx}$  is the drain-source monitoring threshold selected for the corresponding half-bridge.

## Application information

### 10 Application information

**Note:** The following information is given as a hint for the implementation of the device only and shall not be regarded as a description or warranty of a certain functionality, condition or quality of the device.

**Figure 50** Application diagram TLE92108-231QX

**Note:** This is a simplified example of an application circuit. The function must be verified in the real application.

The charge pump buffer capacitor between VS and CP must have a capacitance equal or higher than 470 nF for a stable operation. A higher capacitance can be used to reduce the voltage ripples caused by the charge of the gate of the external MOSFETs during PWM operation.

The flying capacitors between CPC1N/CPC1P and CPC2N/CPC2P must be as close as possible to the TLE92108-231QX.

The decoupling capacitors between VS/GND and VDD/GND must be as close as possible to the TLE92108-231QX and short PCB tracks to the GND plane.

A resistor (RCSOx) and a capacitor (CCSOx) can be placed (not mandatory) at the output of the current sense amplifiers.

## Application information

The device does not need any resistor at the output of the current sense amplifiers. However, if a resistor is used by the application,  $R_{CSOx}$  must be higher than 1 k $\Omega$ . This resistor causes additional current consumption from VDD, which is not taken into account in the electrical characteristics of the datasheet.

$CCSOx$  must be between 10 pF and 400 pF. For a fast reaction time of the CSA output, it is recommended to keep  $CCSOx$  to 10 pF.

If a filter is used at the inputs of the current sense amplifier, the serial resistor may not exceed 5  $\Omega$ .

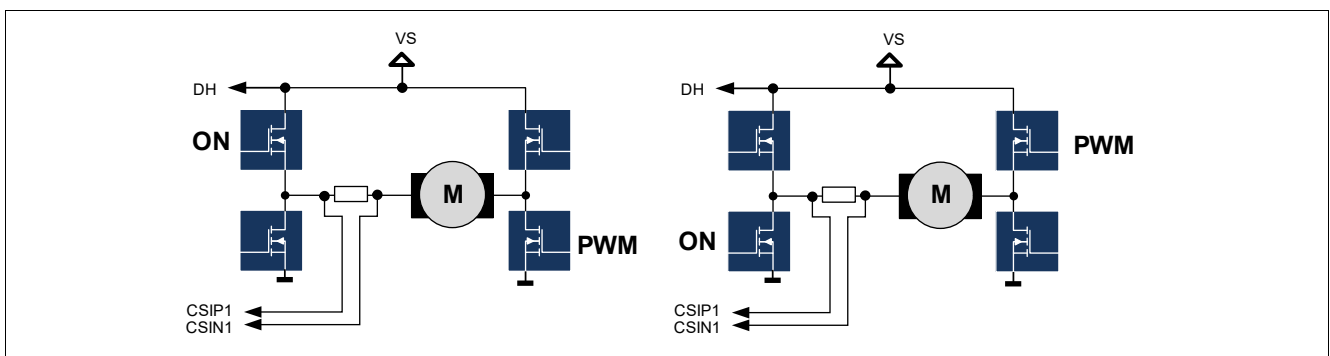

It is possible that the MOSFET gate voltage goes below the source voltage during the commutation of a half-bridge. This depends on the stray inductances at the drain and the source of the MOSFET, the speed of the commutation and the ratio between the MOSFET Gate-Source and Gate-Drain capacitances.

If  $V_{GATE} - V_{SOURCE} < -0.6$  V, a series resistor (e.g. 4.7  $\Omega$ ) in series to GHx and GLx are recommended to limit current delivered by the gate driver during the commutation.

### Shunt resistor in the motor phase

When the shunt resistor is placed in the motor phase, it is highly recommended to apply the PWM to the half-bridge which is not connected to the shunt resistor (**Figure 51**). This avoids a high common mode swing at the inputs of the current sense amplifier.

The drain-source monitoring of the monitoring of the drain-source overvoltage of the high-side MOSFETs must be set to DH - VSHx. Refer to **VDS1**, **VDS2**, HBxD bits.

**Figure 51 PWM with Shunt resistance in the motor phase**

For a proper off-state diagnostic for with the shunt resistor in the motor phase, the corresponding current sense amplifier (CSA) must be deactivated. Otherwise, the activated CSA draws current from its inputs, preventing the internal pull-up source to set the SHx pin to high.

## Package outlines

### 11 Package outlines

**Figure 52 PG-VQFN-48<sup>1)</sup>**

#### Green Product (RoHS compliant)

To meet the world-wide customer requirements for environmentally friendly products and to be compliant with government regulations the device is available as a green product. Green products are RoHS-Compliant (i.e Pb-free finish on leads and suitable for Pb-free soldering according to IPC/JEDEC J-STD-020).
