

Features

- ADC Performance:
 - Analog Multiplexer with 4-full Differential or 8-single Ended Inputs
 - Programmable Amplifier Programmable Gain: 1 to 128
 - Low Noise: 25 nV_{RMS}
 - Programmable Data Rates: 2.5 SPS to 8 kSPS
 - Digital Filter: Simultaneous 50-Hz and 60-Hz Rejection at \leq 20 SPS with Low-Latency Digital Filter
- Integrated Functions:
 - Dual-Matched Programmable Current Sources for Sensor Excitation: 10 μ A to 2000 μ A
 - Internal Reference: 2.5 V
 - Internal Oscillator
 - Internal Temperature Sensor
 - Extended Fault Detection Circuits
 - Self Offset and System Calibration
 - GPIO and GPO pins with external mux control
- Digital Interface
 - 3-/4- wire SPI-Compatible Interface with CRC Checking
- Digital Supply: 2.7 V to 5 V
- Package: 40-lead 6 mm x 6 mm QFN
- Operating Temperature: -40°C to $+125^{\circ}\text{C}$

Applications

- Process Control: PLC/DCS Modules
- Voltage, Current, Temperature, and Pressure Measurement Flow Meters
- Temperature Controllers
- Medical and Scientific Instrumentation

Description

TPC62408 is a precision 4-/8-channel, multiplexed ADC with integrated PGA and many other features, offering accurate measurement for low-bandwidth input signals, and lower-system cost and component count.

The device has a 24-bit delta-sigma converter, with configurable data rates. There are sinc5 filter for optimized noise performance, and low-latency filter for fast settling with 50-/60-Hz rejection for noisy industrial environments.

A low-noise programmable gain amplifier provides 1~128 gain options to amplify low-level signals.

Additionally, it integrates a precision 2.5-V band gap reference and integrated oscillator.

for easy RTD biasing for temperature measurement. Finally, more features such as burnout, CRC, voltage bias, system monitoring, and SPI/Qs are integrated.

The device is available in the QFN 6x6-40 package.

Top View

Table 1. Pin Functions: TPC62408

PIN No.	Name	Type	Description
1	AIN8	AI	Analog Input. Selectable through the cross-point mux.
2	AIN0/REF2-	AI	Analog Input 0 (AIN0)/Reference 2, Negative Input (REF2-). An external reference can be applied between REF2+ and REF2-. REF2- can span from AVSS to AVDD1-1V. Analog Input 0 is selectable through the cross-point mux. Reference 2 can be selected through the REFSEL bits in the setup configuration register.
3	AIN1/REF2+	AI	Analog Input 1 (AIN0)/Reference 2, Positive Input (REF2+). An external reference can be applied between REF2+ and REF2-. REF2+ can span from AVDD1 to AVSS+1V. Analog Input 1 is selectable through the cross-point mux. Reference 2 can be selected through the REFSEL bits in the setup configuration register.
4	AIN2	AI	Analog Input. Selectable through the cross-point mux.
5	AIN3	AI	Analog Input. Selectable through the cross-point mux.
6	REFOUT	AO	Buffered Output of Internal Reference. The output is 2.5 V with respect to AVSS.
7	NC	NC	
8	AVSS	P	Negative Analog Supply. This supply ranges from 0 V to -2.75 V and is nominally set to 0 V.
9	AVDD1	P	Analog Supply Voltage 1. This voltage ranges from 3.0 V minimum to 5.5 V maximum with respect to AVSS.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

PIN No.	Name	Type	Description
10	AVDD2	P	Analog Supply Voltage 2. This voltage should be connected to AVDD1 together.
11	PDSW	AO	Power-Down Switch Connected to AVSS. This pin is controlled by the PDSW bit in the GPIOCON register.
12	NC	NC	
13	CLKIO	DIO	Input 2 for Crystal (XTAL2)/Clock Input or Output (CLKIO). See the CLOCKSEL bit settings in the ADCMODE register for more information.
14	DOUT/RDY	DO	Serial Data Output (DOUT)/Data Ready Output (\overline{RDY}). This pin serves a dual purpose. It functions as a serial data output pin to access the output shift register of the ADC. The output shift register can contain data from any of the on-chip data or control registers. The data-word/control word information is placed on the DOUT/RDY pin on the SCLK falling edge and is valid on the SCLK rising edge. When \overline{CS} is high, the DOUT/RDY output is tri-state. When \overline{CS} is low, and a register is not being read, DOUT/RDY operates as a data ready pin, going low to indicate the completion of a conversion. If the data is not read after the conversion, the pin goes high before the next update occurs. The DOUT/RDY falling edge can be used as an interrupt to a processor, indicating that valid data is available.
15	DIN	DI	Serial Data Input to the Input Shift Register on the ADC. Data in this shift register is transferred to the control registers in the ADC, with the register address (RA) bits of the communications register identifying the appropriate register. Data is clocked in on the rising edge of SCLK.
16	SCLK	DI	Serial Clock Input. This serial clock input is for data transfers to and from the ADC. SCLK has a Schmitt trigger input, making the interface suitable for opto-isolated applications
17	\overline{CS}	DI	Chip Select Input. This is an active low logic input used to select the ADC. \overline{CS} can be used to select the ADC in systems with more than one device on the serial bus. \overline{CS} can be hardwired low, allowing the ADC to operate in 3-wire mode with SCLK, DIN, and DOUT used to interface with the device. When \overline{CS} is high, the DOUT/RDY output is tri-state.
18	ERROR	DI/O	This pin can be used in one of the following three modes:
			Active low error input mode. This mode sets the ADC_ERROR bit in the STATUS register.
			Active low, open-drain error output mode. The STATUS register error bits are mapped to the \overline{ERROR} pin. The \overline{ERROR} pins of multiple devices can be wired together to a common pull-up resistor so that an error on any device can be observed.
			General-purpose output mode. The status of the pin is controlled by the ERR_DAT bit in the GPIOCON register. The pin is referenced between IOVDD and DGND, as opposed to the AVDD1 and AVSS levels used by the GPIO1 and GPIO2 pins. The \overline{ERROR} pin has an active pull-up in this case.
19	SYNC	DI	Synchronization Input. Allows synchronization of the digital filters and analog modulators when using multiple devices.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

PIN No.	Name	Type	Description
20	IOVDD	P	Digital I/O Supply Voltage. IOVDD voltage ranges from 2 V to 5 V. IOVDD is independent of AVDD1 and AVDD2. For example, IOVDD can be operated at 3.3 V when AVDD1 or AVDD2 equals 5 V, or vice versa. If AVSS is set to -2.5 V, the voltage on IOVDD must not exceed 3.6 V.
21	DGND	P	Digital Ground.
22	NC	NC	
23	GPIO0	DI/O	General-Purpose Input/Output. Logic input/output on this pin is referred to the AVDD1 and AVSS supplies.
24	GPIO1	DI/O	General-Purpose Input/Output. Logic input/output on this pin is referred to the AVDD1 and AVSS supplies.
25	GPO2	DO	General-Purpose Output. Logic output on this pin is referred to the AVDD1 and AVSS supplies.
26	AIN4	AI	Analog Input. Selectable through the cross-point mux.
27	AIN5	AI	
28	AIN6	AI	
29	AIN7	AI	
30	NC	NC	
31	NC	NC	
32	NC	NC	
33	NC	NC

35	NC	NC	
36	NC	NC	
37	NC	NC	
38	GPO3	DO	General-Purpose Output. Logic output on this pin is referred to the AVDD1 and AVSS supplies.
39	REF-	AI	Reference 1 Input Negative Terminal. REF- can span from AVSS to AVDD1-1 V. Reference 1 can be selected through the REFSEL bits in the SETUP CONFIGURATION register.
40	REF+	AI	Reference 1 Input Positive Terminal. An external reference can be applied between REF+ and REF-. REF+ can span from AVDD1 to AVSS + 1 V. Reference 1 can be selected through the REFSEL bits in the SETUP CONFIGURATION register.
	EP	P	Exposed Pad. The exposed pad should be soldered to a similar pad on the PCB under the exposed paddle to confer mechanical strength to the package and for heat dissipation. The exposed pad must be connected to AVSS through this pad on the PCB.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

Specifications

Absolute Maximum Ratings (1)

		Min	Max	Unit
Supply Voltage	AVDD1 to AVSS	-0.3	6.5	V
	AVDD1 to DGND	-0.3	6.5	V
	IOVDD to AVSS	-0.3	6.5	V
	IOVDD to DGND	-0.3	6.5	V
	AVSS to DGND	-3.25	0.3	V
Input/Output Pin	Analog Input to AVSS	-0.3	AVDD1 + 0.3	V
	Reference Input to AVSS	-0.3	AVDD1 + 0.3	V
	GPIO to AVSS	-0.3	AVDD1 + 0.3	V
	Digital Input to DGND	-0.3	IOVDD + 0.3	V
	Digital Output to DGND	-0.3	IOVDD + 0.3	V
	Analog and Digital Pin Input Current	-10	10	mA
Temperature	Operating Temperature Range	-40	125	°C
	Maximum Junction Temperature	-40	150	°C
	Storage Temperature Range	-65	150	°C

(1) Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

ESD, Electrostatic Discharge Protection

Symbol	Parameter	Condition	Minimum Level	Unit
HBM	Human Body Model ESD	ANSI/ESDA/JEDEC JS-001 (1)	7	kV
CDM	Charged Device Model ESD	ANSI/ESDA/JEDEC JS-002 (2)	1.5	kV

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

Recommended Operating Conditions

Parameter		Test Conditions	Min	Typ	Max	Units

Timing Requirements

All minimum/maximum specifications at $T_J = -40^{\circ}\text{C}$ to $+125^{\circ}\text{C}$ and all typical specifications at $T_J = 25^{\circ}\text{C}$, IOVDD = 2 V to 5.5 V, DOUT = 20 pF to DGND, unless otherwise noted.

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
SCLK Pulse Width	t_3 SCLK high pulse width	25			ns
	t_4 SCLK low pulse width	25			ns
Read Operation	t_1 $\overline{\text{CS}}$ falling edge to DOUT/RDY active time	0			ns
	IOVDD = 4.5 V to 5.5 V			15	ns
	IOVDD = 2 V to 3.6 V			40	ns
	t_2 SCLK active edge to data valid delay	0			ns
	IOVDD = 4.5 V to 5.5 V			12	ns
	IOVDD = 2 V to 3.6 V			25	ns
	t_5 Bus relinquish time after $\overline{\text{CS}}$ inactive edge	2.5		20	ns
Write Operation	t_6 SCLK inactive edge to $\overline{\text{CS}}$ inactive edge	0			ns
	t_7 SCLK inactive edge to DOUT/RDY high/low	10			ns
	t_8 $\overline{\text{CS}}$ falling edge to SCLK active edge setup time	0			ns
	t_9 Data valid to SCLK edge setup time	8			ns
	t_{10} Data valid to SCLK edge hold time	8			ns
	t_{11} $\overline{\text{CS}}$ rising edge to SCLK edge hold time	5			ns

Timing Diagrams

Figure 1. SPI Read Timing Diagram

Figure 2. SPI Write Timing Diagram

Noise Performance

Delta-sigma ($\Delta\Sigma$) analog-to-digital converters (ADCs) are based on the principle of oversampling. The ratio between modulator frequency and output data rate is called the *oversampling ratio* (OSR). By increasing the OSR, and thus reducing the output data rate, the noise performance of the ADC can be optimized. In other words, the input-referred noise drops when reducing the output data rate because more samples of the internal modulator are averaged to yield one conversion result. Increasing the gain also reduces the input-referred noise, which is particularly useful when measuring low-level signals.

Use following equations to calculate effective resolution and noise-free resolution when using a reference voltage other than 2.5 V.

$$\text{Effective Resolution} = \ln[(2 \cdot V_{\text{REF}} / \text{Gain}) / V_{\text{RMS-Noise}}] / \ln(2) \quad (1)$$

$$\text{Noise-Free Resolution} = \ln[(2 \cdot V_{\text{REF}} / \text{Gain}) / V_{\text{PP-Noise}}] / \ln(2) \quad (1)$$

Table 2. Noise in LSB_{RMS} with Sinc⁵Filter, Global Chop Disabled, and Internal 2.5-V Reference

Detailed Description

Overview

TPC62408 is a precision 4-/8-channel, multiplexed ADC with integrated PGA and many other features, offering accurate measurement for low bandwidth input signals, and lower system cost and component count.

The device has a 24-bit delta-sigma converter, with configurable data rates. There are sinc5 filters for optimized noise performance, and low-latency filter for fast settling with 50-/60-Hz rejection for noisy industrial environments.

The TPC62408 incorporates several features that simplify precision sensor measurements. Key integrated features include:

- Low-noise PGA with integrated signal fault detection
- Low-drift 2.5-V voltage reference
- Dual, matched, sensor-excitation current sources (IDACs)
- Two sets of buffered external reference inputs with reference voltage level detection
- Internal oscillator
- Temperature sensor
- General-purpose input/output pins (GPIOs)
- A low-resistance switch connected to AVSS which can be used to disconnect bridge sensors to reduce current consumption

Analog inputs are configurable to be either single-ended inputs, differential inputs, or a combination of the two. Many of the analog inputs have the following features, which can be programmed by the user. Please refer to the register map for detailed configuration information.

- Two sensor excitation current sources
- Sensor biasing voltage (VBIAS)
- Sensor burn-out current sources

The AVDD analog supply operates with bipolar supplies from ± 1.5 V to ± 2.625 V or with a unipolar supply from 3 V to 5.25 V.

Functional Block Diagram

Figure 3. Functional Block Diagram

Feature Description

Multiplexer

The device contains a flexible input multiplexer; Any analog inputs can be selected as the positive or negative input for the PGA or ADC input.

The multiplexer can also route the excitation current sources to drive external resistive sensors (bridges, RTDs, and thermistors).

The device can provide bias voltages for unbiased sensors (unbiased thermocouples, for example) to analog input pins.

The device also has several system monitor functions which can be measured through the multiplexer:

- The inputs can be shortened together at mid-supply $[(AVDD + AVSS) / 2]$ to measure and calibrate the input offset of the analog front-end and the ADC.
- The system monitor also includes a temperature sensor that provides a measurement of the device temperature.
- The system monitor can also measure the supply voltage, measuring $[(AVDD - AVSS) / 4]$ for the analog supply.
- The system monitor contains a set of burn-out current sources that pull the inputs to either supply if the sensor has burned out and has a high impedance, so that the ADC measures a full-scale reading.

Low-Noise Programmable Gain Amplifier

The device features a low-drift, low-noise, high-input impedance programmable gain amplifier (PGA). The PGA consists of two chopper-stabilized amplifiers and a resistor feedback network that sets the gain of the PGA.

The PGA can be set to be 1, 2, 4, 8, 16, 32, 64, or 128 by using the GAIN[2:0] bits in the gain setting register. Gain is changed inside the device using a variable resistor, R_G . The differential full-scale input voltage range (FSR) of the PGA is defined by the gain setting and the reference voltage used, as shown in

$$FSR = \pm V_{REF} / \text{Gain} \quad (1)$$

The following is the full-scale range when using the internal 2.5-V reference. The PGA gains 64 and 128 are established in the digital domain. When the device is set to 64 or 128, the PGA is set to a gain of 32, and additional gain is established with digital scaling. The input-referred noise does still improve compared to the gain = 32 setting because the PGA is biased with a higher supply current to reduce noise.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

Table 18. PGA Full Scale Range

GAIN SETTING	FSR
1	± 2.5 V
2	± 1.25 V
4	± 0.625 V
8	± 0.313 V
16	± 0.156 V
32	± 0.078 V
64	± 0.039 V
128	± 0.020 V

The PGA can be enabled by setting corresponding values in the AIN_PGA(N)[1:0] bits of the gain setting register, and can also be disabled and bypassed.

PGA Input-Voltage Requirements

The PGA maximum and minimum absolute input voltages are limited by the voltage swing capability of the PGA output. The specified minimum and maximum absolute input voltages (V_{AINP} and V_{AINN}) depend on the PGA gain, the maximum differential input voltage (V_{INMAX}), and the tolerance of the analog power-supply voltages (AVDD and AVSS). Use the maximum voltage expected in the application for V_{INMAX} .

$$AVSS + 0.15 \text{ V} + |V_{INMAX}| \cdot (\text{Gain} - 1) / 2 < V_{AINP}, V_{AINN} < AVDD - 0.35 \text{ V} - |V_{INMAX}| \cdot (\text{Gain} - 1) / 2 \quad (1)$$

where V_{AINP} , V_{AINN} = absolute input voltage, $V_{INMAX} = V_{AINP} - V_{AINN}$ = maximum differential input voltage.

As mentioned in the previous section, PGA gain settings of 64 and 128 are scaled in the digital domain and are not implemented with the amplifier. When using the PGA in gains of 64 and 128, set the gain to be 32 to calculate the absolute input voltage range.

PGA Rail Flags

The PGA output rail detection circuit can be enabled using the FL_RAIL_EN bit in the ADCMODE register. The PGA rail flags (FL_P_RAILP, FL_P_RAILN, FL_N_RAILP, and FL_N_RAILN) in the status register indicate if the positive or negative output of the PGA is closer to the analog supply rails than 150 mV. A flag going high indicates that the PGA is operating outside the linear operating or absolute input voltage range.

Bypassing the PGA

The device can be configured to disable and bypass the PGA by setting the PGA_EN[1:0] bits, and also removes the input range restrictions at a gain of 1. If the PGA is bypassed, the ADC absolute input voltage range extends beyond the AVDD and AVSS power supplies, allowing input voltages at or below ground.

In order to measure single-ended signals that are referenced to AVSS ($AIN_P = V_{IN}$, $AIN_N = AVSS$), the PGA must be bypassed.

Voltage Reference

The device offers an integrated low-drift 2.5-V reference, and for applications that require a different reference voltage value or a ratio metric measurement approach, the device offers two differential reference input pairs (REF+, REF- and REF1+, REF1-).

For external reference, the reference voltage is:

$$V_{REF} = V(REFPx) - V(REFNx) \quad (1)$$

Where $V(REFPx)$ and $V(REFNx)$ are the absolute positive and absolute negative reference voltages

The polarity of the reference voltage internal to the ADC must be positive. The magnitude of the reference voltage together with the PGA gain, establishes the ADC full-scale differential input range as defined by $FSR = \pm V_{REF} / \text{Gain}$.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The ADC also contains an integrated reference voltage monitor. This monitor provides continuous detection of a low or missing reference during the conversion cycle. The reference monitor flags (FL_REF_L0 and FL_REF_L1) are set in the STATUS byte.

Internal Reference

The ADC integrates a precision, low-drift, 2.5-V reference. By default, the internal voltage reference is powered down, and can be enabled by setting corresponding registers.

The REFOUT pin provides a buffered reference output voltage when the internal reference voltage is enabled. Suggest connecting a capacitor between REFOUT and AVSS. A larger capacitor can filter more noise at the expense of a longer reference start-up time.

The capacitor is not required if the internal reference is not used.

The internal reference must be powered on if using the IDACs.

External Reference

The device provides two external reference inputs, which are differential with independent positive and negative inputs.

Internal or external reference buffers can be used to reduce the input current. Without buffering, the reference input current can lead to errors from either high reference source impedance or through reference input filtering.

Be careful that the specified absolute and differential reference voltage requirements should be followed when using internal or external reference.

Reference Buffers

The device has two individually selectable reference input buffers to lower the reference input current. Use the REF_BUFS(N) [1:0] bits to enable or disable the positive and negative reference buffers respectively.

The reference buffers are recommended to be disabled when the internal reference is selected, or when the external reference input is at the supply voltage (REFPx at AVDD or REFNx at AVSS).

Clock Source

The device's clock is either provided by the internal low-drift oscillator or an external clock source on the CLK input, which can be selected by a register. The internal oscillator is used by default after powering up.

Delta-Sigma Modulator

A high-order delta-sigma ($\Delta\Sigma$) modulator is used to convert the analog input voltage into a data stream. The modulator runs at a clock frequency of $f_{MOD} = f_{CLK}/16$, where f_{CLK} is either provided by the internal oscillator or the external clock source

Digital Filter

The device offers a sincN filter and a low-latency filter (low-latency filter) for both filtering and decimation of the digital data stream coming from the delta-sigma modulator. The implementation of the digital filter is determined by the data rate and filter mode.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

Regardless of the FILTER type setting, the oversampling ratio is the same for each given data rate, meaning that the device requires a set number of modulator clocks to output a single ADC conversion data. The output data rate and corresponding oversampling ratio are shown below:

Table 19. ADC Data rate and digital filter oversampling ratio

NOMINAL DATA RATE (SPS) ⁽¹⁾	DATA RATE REGISTER DR[3:0]	OVERSAMPLING RATIO ⁽²⁾

4000	1101	64
8000	1110	64
8000	1111	64

Low-Latency Filter

The low-latency filter can be selected by the FILTER bit. The filter is a finite impulse response (FIR) filter that provides settled data, given that the analog input signal has settled to the final value before the conversion is started. The low-latency filter is especially useful when multiple channels must be scanned in minimal time.

Low-Latency Filter Frequency Response

When the low-latency filter is selected, it provides both 50-Hz and 60-Hz line cycle noise rejection at data rate options at 2.5 SPS, 5 SPS, 10 SPS, and 20 SPS.

Following is the frequency response of the low-latency filter for different data rates.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The following is the bandwidth of the low-latency filter for each data rate.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

NOMINAL DATA RATE (SPS) ⁽¹⁾	-3-dB BANDWIDTH (Hz) ⁽¹⁾
8000	2568.66
4000	1284.33
2000	642.02
1000	401.08
800	331.92
400	174.19
200	88.21
100	44.25
60	26.43
50	22.14
20	8.85
16.67	7.38
10	4.43
5	2.21
2.5	1.11

Note: Valid for the internal oscillator or an external 4.096-MHz clock. Scales proportional to f_{CLK}

Please note that the low-latency filter notches and output data rate scale proportionally with the clock frequency. When an external clock frequency is used, the data rate, conversion time, and filter notches will vary accordingly

Data Conversion Time for the Low-Latency Filter

The data settles in one data period when the low-latency filter is selected. However, a small amount of latency exists to calculate the conversion data from the modulator and do other operations. So the first conversion data takes a little bit longer than subsequent data conversions.

The following table shows the conversion times for the low-latency filter in each data rate and various conversion modes.

NOMINAL DATA RATE ⁽¹⁾ (SPS)	Global Chopper OFF		Global Chopper ON
	FIRST DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾	SECOND AND SUBSEQUENT CONVERSIONS FOR CONTINUOUS CONVERSION MODE (ms) (3)	FIRST or SECOND DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾
8000	0.4525	0.128	0.8945
4000	0.8385	0.256	1.6665
2000	1.6065	0.512	3.2025
1000	2.1185	1.024	4.2265
800	2.3745	1.28	4.7385
400	3.6545	2.56	7.2985
200	6.2145	5.12	12.4185
100	11.3345	10.24	22.6585

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

NOMINAL DATA RATE ⁽¹⁾ (SPS)	Global Chopper OFF		Global Chopper ON
	FIRST DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾	SECOND AND SUBSEQUENT CONVERSATIONS FOR CONTINUOUS CONVERSION MODE (ms) (3)	FIRST or SECOND DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾
60	18.2465	17.152	36.4825
50	21.5745	20.48	43.1385
20	55.3665	51.2	110.7225
16	65.6065	61.44	131.2025
10	106.5665	102.4	213.1225
5	208.9665	204.8	417.9225
2.5	413.7665	409.6	827.5225

Note: Valid for the internal oscillator or an external 4.096-MHz clock. Scales are proportional to f_{CLK}

Note: Conversions start at the rising edge of the START pin or on the final clock edge for a START command

Note: Time does not include the programmable delay set by the DELAY[2:0] bits in the gain setting register.

Note: Subsequent readings in continuous conversion mode do not have the programmable delay time.

SincN Filter

The sincN digital filter is also available. Compared with low-latency filter, it has improved noise performance but has an N-cycle latency to get data out.

SincN Filter Frequency Response

The sincN digital filter's response scales with the data rate and has notches at multiples of the data rate. It has simultaneous 50-Hz and 60-Hz rejection at data rates of 2.5 SPS, 5 SPS, and 10 SPS. And it has only 50-Hz rejection at data rates of 16.6 SPS and 50 SPS, and only 60-Hz rejection at data rates of 20 SPS and 60 SPS.

The following is the bandwidth of the sincN filter for each data rate.

NOMINAL DATA RATE (SPS) ⁽¹⁾	-3-dB BANDWIDTH (Hz) ⁽¹⁾
8000	1630.80
4000	815.40
2000	407.70
1000	203.85
800	163.08
400	104.78
200	52.39
100	26.19
60	15.72
50	13.10
20	5.24
16.67	4.37
10	2.62

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

NOMINAL DATA RATE (SPS) ⁽¹⁾	-3-dB BANDWIDTH (Hz) ⁽¹⁾
5	1.31
2.5	0.65

Note: Valid for the internal oscillator or an external 4.096-MHz clock. Scales are proportional to f_{CLK} .

And filter notches and output data rate scale proportionally with the clock frequency.

Data Conversion Time for the SincN Filter

The sincN filter normally takes 5 (for ODR \geq 800Hz) or 3 (for ODR \leq 400Hz) conversions to settle, and it needs different amounts of time to complete a conversion.

Following are the conversion times for the sincN filter for each ADC data rate and various conversion modes

NOMINAL DATA RATE ⁽¹⁾ (SPS)	Global Chopper OFF		Global Chopper ON
	FIRST DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾	SECOND AND SUBSEQUENT CONVERSIONS FOR CONTINUOUS CONVERSION MODE (ms) ⁽³⁾	FIRST or SECOND DATA FOR CONTINUOUS CONVERSION MODE OR SINGLE-SHOT CONVERSION MODE ⁽²⁾ (ms) ⁽³⁾
8000	0.708	0.128	1.406
4000	1.35	0.256	2.69
2000	2.63	0.512	5.25
1000	5.19	1.024	10.37
800	6.47	1.28	12.93
400	7.75	2.56	15.49
200	15.43	5.12	30.85
100	30.79	10.24	61.57
60	51.238	17.056	102.466
50	61.51	20.48	123.01
20	153.67	51.2	307.33
16	184.39	61.44	368.77
10	307.27	102.4	614.53
5	614.47	204.8	1228.93
2.5	1228.87	409.6	2457.73

Note: Test is valid for the internal oscillator or an external 4.096-MHz clock. Scales are proportional to f_{CLK} .

Note: Conversions start at the rising edge of the START pin or on the final clock edge for a START command.

Note: Time does not include the programmable delay set by the DELAY bits in the gain setting register.

Note: Subsequent readings in continuous conversion mode do not have the programmable delay time.

Note on Conversion Time

There is a programmable conversion delay which can be added before the conversion starts. This delay allows for additional settling time for input filtering on the analog inputs and for the antialiasing filter after the PGA. Also, overhead time is needed to convert the modulator samples into an ADC conversion result. This overhead time includes any necessary offset or gain compensation after the digital filter to get the final data result.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The first conversion time when the device is in continuous conversion mode, or each conversion time in single-shot conversion mode, includes the programmable conversion delay, the modulator sampling time, and the overhead time. And the second and subsequent conversions in continuous mode are the normal data period (period corresponding to the data rate).

50-Hz and 60-Hz Line Cycle Rejection

The digital filter provides enhanced rejection of coupled noise for data rates of 60 SPS and less. Please refer to the digital filter sections for frequency response. The best possible rejection ratio can be obtained by using an accurate ADC clock.

Global Chop Mode

Although the device has a low-drift PGA and modulator to achieve very low input voltage offset drift, a small amount of offset voltage drift is sometimes left in normal measurement. The device has a global chop option to reduce the offset voltage and its drift to very low levels.

The global chop mode can be enabled using the G_CHOP bit. When the global chop is enabled, the ADC performs two internal conversions to cancel the input offset voltage. The first conversion is taken with normal input polarity. And then the ADC reverses the internal input polarity and does a second conversion. Finally the average of the two conversions is given out as the final result, removing the offset voltage.

In global chop mode, sequences are similar to taking consecutive single-shot conversions and swapping the input on each conversion. In continuous conversion mode with the global chop mode enabled, the first conversion result is available after the ADC takes two separate conversions with settled data, and subsequent conversions complete in half the time as the first conversion completed.

In global chop mode, if the data rate in use has 50-Hz and 60-Hz frequency response notches, the null frequencies remain unchanged.

The global chop mode also reduces the ADC noise by a factor of $\sqrt{2}$ because two conversions are averaged.

If necessary, the programmable conversion delay should be increased for settling of external components.

Excitation Current Sources (IDACs)

The device provides two matched current sources, which can be used as excitation current to resistive temperature devices (RTDs), thermistors, diodes, and other resistive sensors that require constant current biasing, to reduce system complexity. The current sources are programmable to output values between 10 μ A to 2000 μ A by IMAG registers.

The internal reference should be enabled for IDAC operation. And the IDAC requires voltage headroom to the positive supply to operate. This voltage headroom is the compliance voltage.

Bias Voltage Generation

The device has an internal bias voltage generator which can be set to two different levels, $(AVDD + AVSS) / 2$ and $(AVDD + AVSS) / 12$, by VB_LEVEL register, . The VBIAS can be used to bias thermocouples to within the common-mode voltage range of the PGA.

System Monitor

The device provides a set of system monitor functions, to measure the on-chip temperature, analog power supply, digital power supply, or use current sources to detect sensor malfunction.

Internal Temperature Sensor

The internal temperature sensor can be selected by the input multiplexer. The temperature sensor outputs a voltage proportional to the temperature as specified in the Electrical characteristic table

If enabled, PGA gain should be set to 4 for the temperature sensor measurement to remain within the allowed absolute input voltage range of the PGA.

Power Supply Monitors

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The device provides monitor functions for the analog and digital interface power supply (AVDD and IOVDD), which can be selected by the SYS_MON register.

The power-supply voltages are divided by a resistor network to reduce the voltages to within the ADC input range, (AVDD – AVSS) / 4 and IOVDD/4.

Burn-Out Current Sources

The device provides Burn Out Current Source (BOCS) which can be enabled by BURNOUT_EN registers. The current can be used to detect external sensor malfunctions. Current sources can be set to 0.2 μ A, 1 μ A, and 10 μ A.

When enabled, one BOCS sources current is routed to the selected positive analog input (AIN_P) and the other BOCS sinks current from the selected negative analog input (AIN_N). If there is an open-circuit in a burned-out sensor, these BOCSs pull the positive input towards AVDD and the negative input towards AVSS, resulting in a full-scale reading. A full-scale reading can also indicate that the sensor is overloaded or the reference voltage is absent. A near-zero reading can indicate a shorted sensor.

Status Register

POR Flag

After the power supplies are turned on, the ADC remains in reset until AVDD and IOVDD voltages exceed the respective power-on reset (POR) voltage thresholds. If a POR event has occurred, the FL_POR bit is set. This flag indicates that a POR event has occurred and has not been cleared. This flag is cleared with a user register write to set the bit to 0.

UVLO Flag

When the supply voltage falls below Under Voltage Lock Out (UVLO) thresholds, a FL_UVLO bit is set.

RDY Flag

The RDY flag indicates that the device has started up and is ready to receive a configuration change.

PGA Output Voltage Rail Monitors

The PGA contains an integrated output-voltage monitor. If the PGA output voltage exceeds AVDD – 0.15 V or drops below AVSS + 0.15 V, a flag is set to indicate that the output has gone beyond the output range of the PGA. Each PGA output V_{OUTN} and V_{OUTP} can trigger an overvoltage or undervoltage flag. So total four flags can be set by register bits FL_P_RAILP, FL_P_RAILP, FL_N_RAILP and FL_N_RAILP.

If the PGA is bypassed, then the rail monitor is still operational and is sensing the connection at the input of the ADC.

The flags are updated (set or cleared) only at the end of a conversion cycle. And a fault is latched during a conversion cycle.

Reference Monitor

A reference detection circuit can be selected to continuously monitor the differential ADC reference inputs, for a shorted or missing reference voltage. The reference detection circuit offers two thresholds, 300 mV and the second threshold is $1/3 \cdot (AVDD - AVSS)$. The flag bit will be latched after each conversion in the STATUS register if the voltage is below the threshold.

A reference voltage less than 300 mV can indicate a potential short on the reference inputs or, in case of a ratio metric RTD measurement, a broken wire between the RTD and the reference resistor.

When the reference monitor is enabled, a 10 M Ω resistor is connected between the selected REFPx and REFNx inputs. The resistor can be used to detect a floating reference input. But it lowers the input reference input impedance and can lead to gain error.

ADC_ERROR

The ADC_ERROR bit in the status register is set when an over- range or underrange occurs at the output of the ADC during the conversion process. The ADC also outputs all 0s or all 1s respectively when an underrange or overrange occurs. This flag is reset only when the underrange or overrange is removed.

REG_ERROR

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The device has a REG_CHECK function to be used to monitor any change in the value of the user registers. And the REG_ERROR bit is indicated if the content of one of the internal registers has changed from the value calculated when the register integrity check was activated.

General-Purpose Inputs and Outputs (GPIOs)

The device has two general-purpose digital input/output pins (GPIO0, GPIO1) and two general-purpose digital output pins (GPO2, GPO3). As the naming suggests, the GPIO0 and GPIO1 pins can be configured as inputs or outputs, but GPO2 and GPO3 are outputs only. The GPIO and GPO pins are enabled using the bits in the GPIOCON register.

The logic levels for these pins are referenced to AVDD and AVSS;

The ERROR pin can also be used as a general-purpose output by setting the ERR_EN bits in the GPIOCON register. The ERROR pin has an active pull-up, and the logic level for the pin is referenced to IOVDD and DGND.

Low-Side Power Switch

The device provides a low-side power switch between REFN0 and AVSS-SW by the PDSW bit. The switch can be used to reduce system power consumption in resistive bridge sensor applications by powering down the bridge circuit between conversions.

Cyclic Redundancy Check (CRC)

The device has a checksum mode that can be used to improve interface robustness. The checksum mode ensures that only valid data is written to a register and data read is validated.

If an error occurs during a register write, the CRC_ERROR bit is set in the status register. And to ensure that the register write was successful, it is important to read back the register and verify the checksum.

During a write operation, the checksum is calculated using the 8-bit command word and the 8- to 24-bit data, and the following polynomial is always used for CRC checksum calculations:

$$x^8 + x^2 + x + 1 \quad (1)$$

During read operations, the checksum is calculated using the command word and the 8- to 32-bit data output. Users can select between the above polynomial and a similar XOR function by CRC_EN bits. The XOR function requires less time for the host microcontroller to process than the polynomial-based checksum.

The 8bit checksum is appended to the end of each read and write transaction. Following shows SPI write and read transactions, respectively.

SPI Write with CRC

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

SPI Read with CRC

Calibration

The device allows the user to read and write the calibration coefficients of the device for gain and offset. A read or write of the offset and gain registers can be performed at any time except during an internal or self calibration.

And the user can also trigger calibration mode for automotive gain and offset calibration, refer to the calibration mode section for details.

Offset Calibration

The offset (zero-scale) registers are 24-bit registers that can be used to compensate for any offset error in the ADC or in the system. There are 4 offset registers, which are assigned to the corresponding setup.

Gain Calibration

The gain (full-scale) registers are 24-bit registers that can be used to compensate for any gain error in the ADC or in the system. There are 4 gain registers, which are assigned to the corresponding setup.

Configuration Overview

After powering on-or resetting, the default configuration is as follows:

- Channel configuration. CH0 is enabled, AIN0 is selected as the positive input, and AIN1 is selected as the negative input. Setup 0 is selected.
- Setup configuration. The input buffers are disabled, and the external reference is selected.
- ADC mode. Continuous conversion mode, the internal oscillator, and single-cycle settling are enabled.
- Interface mode. CRC is disabled, and data + status output is disabled.

ADC Setups

The device has four independent setups. Each setup consists of the following four registers:

- Setup configuration register
- Filter configuration register
- Offset register
- Gain register

Each setup is a group of these registers, and the setup is selectable from the channel registers. This allows each channel to be assigned to one of 4 separate setups.

The motivation to have 4 setups is that the user may need different speed/noise/offset/gain requirements on particular inputs versus other inputs. So the device provides flexibility for the configuration of each channel.

Device Functional Modes

The device operates in several different modes: Power Down Mode, Standby Mode, Single conversion Mode, Continuous Conversion Mode and Calibration Mode.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

Standby Mode

In standby mode, most blocks are powered down, and the registers still maintain their contents. The internal reference, internal oscillator remains active, if they are selected or enabled by corresponding registers.

Continuous Conversion Mode

Continuous conversion is the default mode after powering up. In this mode, the device converts continuously, and the **RDY** bit in the status register goes low each time when a conversion is complete. If **CS** is low, the **DOUT/RDY** line also goes low when a conversion is complete. And **DOUT/RDY** goes high when the data is read from the data register. To read a conversion, the user writes to the communications register, indicating that the next operation is a read. The user can read this register additional times if needed. However, the user must ensure that the data register is not being accessed at the completion of the next conversion.

When several channels are enabled, the ADC automatically sequences through each enabled channel from the lowest enabled channel to the highest, performing one conversion on each channel. When all channels are converted, the sequence starts again with the first channel.

The data register is updated as soon as the latest conversion result is available. The **DOUT/RDY** pin pulses low each time a conversion is available. The user must read the conversion result before the ADC finishes conversion of the next channel; otherwise, the conversion result is lost.

If the **DATA_STAT** bit in the interface mode register is set to 1, the contents of the status register along with the conversion data, are output each time the data register is read. The status register indicates the channel to which the conversion corresponds.

Continuous Conversion Mode

Continuous Read Mode

The device also provides a continuous read mode, in which it is not required to write the communications register before the ADC data is read. To enable continuous read mode, set the **CONTREAD** bit in the interface mode register.

In this mode, the required number of **SCLKs** should be applied after **DOUT/RDY**

goes low to read the conversion result, and then **DOUT/RDY** returns high until the next conversion is available. In this mode, the data can be read only once.

If multiple ADC channels are enabled, each channel is output in turn, with the status bits being appended to the data if the **DATA_STAT** bit is set. The status register indicates the channel to which the conversion corresponds.

Hold **DIN** low in continuous read mode until an instruction is to be written to the device.

To exit continuous read mode, issue a dummy read of the ADC data register command (0x44) while **RDY** is low. The other method is to apply a software reset, that is 64 **SCLKs** with **CS** = 0 and **DIN** = 1. This resets the ADC and all register contents.

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

Continuous Read Mode

The device provides a single conversion mode, in which it performs a single conversion and then enters standby mode after completion. **DOUT/RDY** goes low to indicate the completion of a conversion. After the data word is read from the data register, **DOUT/RDY** goes high. The data register can be read several times if needed, even when **DOUT/RDY** is high.

If several channels are enabled, the ADC automatically sequences through the enabled channels and performs a conversion on each channel. After the conversions are done, it returns to standby mode.

When a conversion is started, **DOUT/RDY** goes high, and goes low as soon as the conversion data is available. Then the ADC selects the next channel and begins a conversion. The user must read the present conversion while the next conversion is being performed.

If the **DATA_STAT** bit in the interface mode register is set to 1, the contents of the status register are output each time the data register is read along with the conversion data.

Single Conversion Mode

Calibration Mode

The device provides three calibration modes which can be used to eliminate the offset and gain errors automatically:

- Internal zero-scale calibration mode
- System zero-scale calibration mode
- System full-scale calibration mode

Only one channel can be active during calibration. To start a calibration, write the relative value to the **MODE** bits. When the calibration initiates, the **DOUT/RDY** pin and the **RDY** bit in the status register go high. After the calibration is complete, the contents of the corresponding offset or gain register are updated, and the **RDY** bit in the status register is set, the **DOUT/RDY** pin returns low (if **CS** is low). Then for the following conversions, the ADC conversion result is scaled using the calibration registers at first and then written to the data register.

During an internal offset calibration, the selected positive analog input pin is disconnected, and both modulator inputs are connected internally to the selected negative analog input pin.

System calibrations expect the system zero-scale (offset) and system full-scale (gain) voltages to be applied to the ADC pins before initiating the calibration modes. As a result, errors external to the ADC can be removed on system level.

If required, the offset calibration must always be performed before a full-scale calibration.

A calibration process is just like an ADC conversion. All calibrations require a time that is equal to the settling time of the selected filter and the output data rate to be completed.

The calibration registers can be read or written with user's own calibration coefficients at any time except during an internal or self calibration.

The following equations show the calibration calculations. In unipolar mode, the ideal relationship is as follows:

$$\text{Data} = V_{IN}/V_{REF} \cdot 2^{23} - (\text{Offset} - 0x800000) \cdot (\text{Gain}/0x400000) \cdot 2 \quad (1)$$

In bipolar mode, the ideal relationship is as follows:

$$\text{Data} = V_{IN}/V_{REF} \cdot 2^{23} - (\text{Offset} - 0x800000) \cdot (\text{Gain}/0x400000) + 0x800000 \quad (1)$$

Serial Interface

The TPC62408 supports an SPI-compatible bus.

SPI Interface

In SPI mode, the device is controlled through a 3-wire or 4-wire serial interface. The interface operates in SPI Mode 3 and can be operated with \overline{CS} tied low. In SPI Mode 3, SCLK idles high, the falling edge of SCLK is the drive edge, and the rising edge of SCLK is the sample edge. This means that data is clocked out on the falling/drive edge and data is clocked in on the rising/sample edge

Register Map Accessing

On power-up or after a reset, the digital interface default state expects a write to the communications register; therefore, all communication begins with writing to the communications register.

The data written to the communications register determines which register is being accessed and whether the next operation is a read or write.

The writing and reading operations to a register are shown below:

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

100101	RESERVED		
100110	RESERVED		

STATUS Register (0x00)

The status register is an 8-bit register that contains ADC and serial interface status information. It can optionally be appended to the data register by setting the DATA_STAT bit in the interface mode register (Bit 6, Register 0x02).

Bits	Bit Name	Settings	Description	Reset	Access
7	<u>RDY</u>		The status of RDY is output to the DOUT/RDY pin whenever CS is low and a register is not being read. This bit goes high when the ADC has written a new result to the data register. In ADC calibration modes, this bit goes high when the ADC has written the calibration result. RDY is brought low automatically by a read of the data register.	0x0	R
		0	Awaiting new data result		
		1	New data result available		
6	ADC_ERROR		This bit, by default, indicates if an ADC over range or under range has occurred. The ADC result is clamped to \pm full scale if an over range or under range occurs. This bit is updated when the ADC result is written and is cleared by removing the over range or under range condition on the analog inputs.	0x0	R
		0	No error		
		1	Error		
5	CRC_ERROR		This bit indicates if a CRC error has occurred during a register write. For register reads, the host microcontroller determines if a CRC error has occurred. This bit is cleared by a read of this register.	0x0	R
		0	No error		
		1	CRC error		
4	REG_ERROR		This bit indicates if the content of one of the internal registers has changed from the value calculated when the register integrity check was activated. The check is activated by setting the REG_CHECK bit in the interface mode register. This bit is cleared by clearing the REG_CHECK bit.	0x0	R
		0	No error		
		1	Error		
[3:0]	CHANNEL		These bits indicate which channel was active for the ADC conversion whose result is currently in the data register. This	0x0	R

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

		may be different from the channel currently being converted. The bits are a direct mapping from the Channel x registers; therefore, Channel 0 results in 0x0 and Channel 7 results in 0x7.		
	0	Channel 0		
	1	Channel 1		
	10	Channel 2		
	11	Channel 3		
	100	Channel 4		
	101	Channel 5		
	110	Channel 6		
	111	Channel 7		

ADC MODE Register (0x01)

The ADC mode register controls the operating mode of the ADC and the master clock selection. A write to the ADC mode register resets the filter and the RDY bits and starts a new conversion or calibration.

Bits	Bit Name	Settings	Description	Reset	Access
15	REF_EN		Enables internal reference and outputs a buffered 2.5 V to the REFOUT pin.	0x0	RW
		0	Disabled		
		1	Enabled		
14	FL_RAIL_EN		Enable PGA rail detector:	0x0	RW
		0	Disabled		
		1	Enabled		
13	SING_CYC		This bit can be used when only a single channel is active to set the ADC to output only at the settled filter data rate.	0x1	RW
		0	Disabled		
		1	Enabled		
[12:11]		RESERVED	These bits are reserved. Set to 0.	0x0	R
[10:8]	DELAY		These bits allow a programmable delay to be added after a channel switch to allow settling of external circuitry before the ADC starts processing its input.	0x0	RW
		000	14*Tmod		
		001	25*Tmod		
		010	64*Tmod		
		011	256*Tmod		
		100	1024*Tmod		
		101	2048*Tmod		
		110	4096*Tmod		
		111	1*Tmod		

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

7	RESERVED		When set to 1, the frequency of modulator and thus the output ODR is doubled.	0x0	RW
[6:4]	MODE		These bits control the operating mode of the ADC. Details can be found in the Operating Modes section.	0x010	RW
		000	Continuous conversion mode		
		001	Single conversion mode		
		010	Standby mode		
		011	RESERVED.		
		100	Internal offset calibration		
		110	System offset calibration		
		111	System gain calibration		
[3:2]	CLOCKSEL		This bit is used to select the ADC clock source. Selecting the internal oscillator also enables the internal oscillator.	0x00	RW
		0	Internal oscillator		
		1	Internal oscillator output on XTAL2/CLKIO pin		
		10	External clock input on XTAL2/CLKIO pin		
		11	RESERVED (internal oscillator)		
[1]	RESERVED		These bits are reserved. Set to 0.	0x0	R
[0]	SOFTRST		self clear after reset	0x0	W

Interface Mode Register(0x02)

The interface mode register configures various serial interface options.

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved. Set to 0.	0x0	R
12	ALT_SYNC		This bit enables a different behavior of the SYNC pin to allow the use of SYNC as a control for conversions when cycling channels. (For details, see the description of the SYNC_EN bit in the GPIO Configuration Register.)	0x0	RW
		0	Disabled		
		1	Enabled		
[11:9]	RESERVED		These bits are reserved. Set to 0.	0x0	R
8	DOUT_RESET		This bit prevents the DOUT/RDY pin from switching from outputting DOUT to outputting RDY soon after the last rising edge of SCLK during a read operation. Instead, the DOUT/RDY pin continues to output the LSB of the data until CS goes high, providing longer hold times for the SPI master to sample the LSB of the data. When this bit is set, CS must not be tied low.	0x0	RW
		0	Disabled		
		1	Enabled		
7	CONTREAD		This bit enables continuous read of the ADC data register. To use continuous read, configure the ADC in continuous	0x0	RW

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

		conversion mode. For more details, see the Operating Modes section.		
		0 Disabled		
		1 Enabled		
6	DATA_STAT	This bit enables the status register to be appended to the data register when read so that channel and status information is transmitted with the data. This is the only way to ensure that the channel bits read from the status register correspond to the data in the data register.	0x0	RW
		0 Disabled		
		1 Enabled		
5	REG_CHECK	This bit enables a register integrity checker that can be used to monitor any change in the value of the user registers. To use this feature, configure all other registers as desired, with this bit cleared. Then write to this register to set the REG_CHECK bit to 1. If the contents of any of the registers change, the REG_ERROR bit is set in the status register. To clear the error, set the REG_CHECK bit to 0. Neither the interface mode register nor the ADC data or status register is included in the registers that are checked. If a register must have a new value written, clear this bit first; otherwise, an error is flagged when the new register contents are written.	0x0	RW
		0 Disabled		
		1 Enabled		
		This bit is reserved. Set to 0.		
[3:2]	CRC_EN	Enables CRC protection of register reads/writes. CRC increases the number of bytes in a serial interface transfer by one. See the CRC Calculation section for more details.	0x00	RW
		0 Disabled.		
		1 XOR checksum enabled for register read transactions. Register writes still use CRC with these bits set.		
		10 CRC checksum enabled for read and write transactions.		
		11 Reserved		
1	RESERVED	This bit is reserved. Set to 0.	0x0	R
0	WL16	Changes the ADC data register to 16 bits. The ADC is not reset by a write to the interface mode register; therefore, the ADC result is not rounded to the correct word length immediately after writing to these bits. The first new ADC result is correct.	0x0	RW
		0 24-bit data		
		1 16-bit data		

Register Checksum Register (0x03)

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

The register check register is a 24-bit checksum calculated by XOR'ing the contents of the user registers and some non-accessible registers (Trim bits). The REG_CHECK bit in the interface mode register must be set for this to operate; otherwise, the register reads 0.

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	REGISTER_CHECK		This register contains the 24-bit checksum of user registers when the REG_CHECK bit is set in the interface mode register.	0x000000	R

ADC Data Register (0x04)

The data register contains the ADC conversion result. The encoding is offset binary; however, it can be changed to unipolar by the BI_UNIPOLAR bit in the setup configuration register. Reading the data register brings the RDY bit and pin high if they are low. The ADC result can be read multiple times; however, because RDY has been brought high, it is not possible to know if another ADC result is imminent. The ADC does not write a new result into the data register if the register is currently being read.

Bits	Bit Name	Settings	Description	Reset	Access
[23:0]	DATA		This register contains the ADC conversion result. If the DATA_STAT bit is set in the interface mode register, the status register is appended to this register when read, making this a 32-bit register. If WL16 is set in the interface mode register, this register is set to a length of 16 bits.	0x000000	R

GPIO Configure Register (0x06)

The GPIO configuration register controls the general-purpose I/O pins of the ADC.

Bits	Bit Name	Settings	Description	Reset	Access
15	RESERVED		This bit is reserved. Set to 0.	0x0	R
14	PDSW		This bit enables/disables the power-down switch function. Setting the bit allows the pin to sink current. This function can be used for bridge sensor applications where the switch controls the power-up/power-down of the bridge.	0x0	RW
13	OP_EN2_3		This bit enables the GPO2 and GPO3 pins. Outputs are referenced between AVDD1 and AVSS.	0x0	RW
12	RESERVED		RESERVED	0x0	RW
11	SYNC_EN		This bit enables the SYNC pin as a sync input. When set low, the SYNC pin holds the ADC and filter in reset until SYNC goes high. An alternative operation of the SYNC pin is available when the ALT_SYNC bit in the interface mode register is set. This mode works only when multiple channels are enabled. In such cases, a low on the SYNC pin does not immediately reset the filter/ modulator. Instead, if the SYNC pin is low when the channel is due to be switched, the modulator and filter are prevented from starting a new conversion. Bringing SYNC high begins the next conversion. This alternative sync mode allows SYNC to be used while cycling through channels.	0x1	RW
	0	Disabled			
	1	Enabled			

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

			These bits enable the ERROR pin as an error input/output.	0x0	RW
		0	Disabled		
		1	ERROR is an error input. The (inverted) readback state is OR'ed with other Error sources and is available in the ADC_ERROR bit in the status register. The ERROR pin state can also be read from the ERR_DAT bit in this register.		
[10:9]	ERR_EN	10	ERROR is an open-drain error output. The status register error bits are OR'ed, inverted, and mapped to the ERROR pin. ERROR pins of multiple devices can be wired together to a common pull-up resistor so that an error on any device can be observed.		
		11	ERROR is a general-purpose output. The status of the pin is controlled by the ERR_DAT bit in this register. This is referenced between IOVDD and DGND, as opposed to the AVDD1 and AVSS levels used by the general-purpose I/O pins. It has an active pull-up in this case.		
8	ERR_DAT		This bit determines the logic level at the ERROR pin if the pin is enabled as a general-purpose output. It reflects the readback status of the pin if the pin is enabled as an input.	0x0	RW
7	GP_DATA3		This bit is the write data for GPO3.	0x0	W
6	GP_DATA2		This bit is the write data for GPO2.	0x0	W
5	IP_EN1		This bit turns GPIO1 into an input. Input should equal AVDD1 or AVSS.	0x0	RW
		0	Disabled		
		1	Enabled		
4	IP_EN0		This bit turns GPIO0 into an input. Input should equal AVDD1 or AVSS.	0x0	RW
		0	Disabled		
		1	Enabled		
3	OP_EN1		This bit turns GPIO1 into an output. Outputs are referenced between AVDD1 and AVSS.	0x0	RW
		0	Disabled		
		1	Enabled		
2	OP_EN0		This bit turns GPIO0 into an output. Outputs are referenced between AVDD1 and AVSS.	0x0	RW
		0	Disabled		
		1	Enabled		
1	GP_DATA1		This bit is the readback or write data for GPIO1.	0x0	RW
0	GP_DATA0		This bit is the readback or write data for GPIO0.	0x0	RW

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC
ID Register (0x07)

The ID register returns a 16-bit ID. For the TPC62408, this is 0x6240.

Bits	Bit Name	Settings	Description	Reset	Access
[15:0]	ID		The ID register returns a 16-bit ID code that is specific to the ADC.	0x6240	R

DIEID1 Register (0x08)

The ID register returns a 16-bit ID.

Bits	Bit Name	Settings	Description	Reset	Access
[15:0]	ID1		The ID register returns a 16-bit DIE ID code.		R

DIEID2 Register (0x09)

The ID register returns a 16-bit ID.

Bits	Bit Name	Settings	Description	Reset	Access
[15:0]	ID2		The ID register returns a 16-bit DIE ID code.		R

CH0 Register (0x10)

The channel registers are 16-bit registers that are used to select which channels are currently active, which inputs are selected for each channel.

Bits	Bit Name	Settings	Description	Reset	Access
15	CH_EN0		This bit enables Channel 0. If more than one channel is enabled, the ADC automatically sequences between them.	0x1	RW
		0	Disabled		
		1	Enabled (default)

Setup Configuration 0 (0x20)

The setup configuration registers are 16-bit registers that configure the reference selection, input buffers, burnout currents, and output coding of the ADC.

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved. Set to 0.	0x0	R
12	BI_UNIPOLAR0		This bit sets the output coding of the ADC for Setup 0.	0x1	RW
		0	Unipolar coded output		
		1	Offset binary coded output		
			Reference input buffer enable. These bits turn on the buffers of the positive and negative reference inputs. This offers a high impedance input for an external reference source and isolates it from the switch capacitor reference sampling input of the ADC. Use both reference buffers together.	0x0	RW

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

		00	Reference input buffers disabled		
		01	REFN Buf En		
		10	REFP Buf En		
		11	Reference input buffers enabled		
[9:8]	AIN_PGA_0[1:0]		Analog input PGA enable. These bits turn on the PGAs of the positive and negative analog inputs. This offers a high impedance input to the device and isolates the sensor/signal for measurement from the switch capacitor sampling input of the ADC. Use both analog input buffers together.	0x0	RW
		00	Analog input PGAs disabled		
		01/10	Analog input PGAs disabled		
		11	Analog input PGAs enabled		
7	RESERVED		These bits are reserved. Set to 0.	0x0	RW
6	RESERVED		These bits are reserved. Set to 0.	0x0	R
[5:4]	REF_SEL0		These bits allow selection of the reference source for ADC conversion on Setup 0.	0x0	RW
		00	External reference supplied to REF+ and REF- pins		
		01	External Reference 2 supplied to AIN1/REF2+ and AIN0/REF2- pins		
		10	Internal 2.5 V reference; this reference must also be enabled in the ADC mode register		
		11	Reserved. Don't write.		
[3:2]	RESERVED		These bits are reserved. Set to 0.	0x0	R
[1:0]	BURNOUT_EN[1:0]		[BURNOUT_EN1, BURNOUT_EN0] The bits enable a current source on the positive analog input selected and a current sink on the negative analog input selected. The burnout currents are useful in diagnosis of an open wire, whereby the ADC result goes to full scale. Enabling the BURNOUT currents during measurement results in an offset voltage on the ADC reading of approximately 1 μ V. This means the strategy for diagnosing an open wire operates best by turning on the BURNOUT currents at intervals, before or after precision measurements.	0x0	RW
		00	OFF		
		01	Burn-out current sources enabled, 10- μ A setting		
		10	Burn-out current sources enabled, 0.2- μ A setting		
		11	Burn-out current sources enabled, 1- μ A setting		

Setup Configuration 1~3 (0x21~23)

The setup configuration registers are 16-bit registers that configure the reference selection, input buffers, burnout currents, and output coding of the ADC.

Bits	Bit Name	Settings	Description	Reset	Access
[15:13]	RESERVED		These bits are reserved. Set to 0.	0x0	R

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

12	BI_UNIPOLAR(N)		This bit sets the output coding of the ADC for Setup N (N=1~3).	0x1	RW
		0	Unipolar coded output		
		1	Offset binary coded output		
[11:10]	REF_BUF_(N) [1:0]		Reference input buffer enable. These bits turn on the buffers of the positive and negative reference inputs. This offers a high impedance input for an external reference source and isolates it from the switch capacitor reference sampling input of the ADC. Use both reference buffers together.	0x0	RW
		00	Reference input buffers disabled		
		11	Reference input buffers enabled		
[9:8]	AIN_PGA_(N)[1:0]		Analog input PGA enable. These bits turn on the PGAs of the positive and negative analog inputs. This offers a high impedance input to the device and isolates the sensor/signal for measurement from the switch capacitor sampling input of the ADC. Use both analog input buffers together.	0x0	RW
		00	Analog input PGAs disabled		
		01/10	Analog input PGAs disabled		
		11	Analog input PGAs enabled		
7	RESERVED		These bits are reserved. Set to 0.	0x0	RW
6	RESERVED		These bits are reserved. Set to 0.	0x0	R
[5:4]	REF_SEL(N)		These bits allow selection of the reference source for ADC conversion on Setup N.	0x0	RW
		00	External reference supplied to REF+ and REF- pins		
		01	External Reference 2 supplied to AIN1/REF2+ and AIN0/REF2- pins		
		10	Internal 2.5 V reference; this reference must also be enabled in the ADC mode register		
		11	Reserved. Don't write.		
[3:2]	RESERVED		These bits are reserved. Set to 0.	0x0	R
[1:0]	BURNOUT_EN(N) [1:0]		[BURNOUT_EN(N)1, BURNOUT_EN(N)0] The bits enable a current source on the positive analog input selected and a current sink on the negative analog input selected. The burnout currents are useful in diagnosis of an open wire, whereby the ADC result goes to full scale. Enabling the BURNOUT currents during measurement results in an offset voltage on the ADC reading of approximately 1 μ V. This means the strategy for diagnosing an open wire operates best by turning on the BURNOUT currents at intervals, before or after precision measurements.	0x0	RW
		00	OFF		
		01	Burn-out current sources enabled, 10- μ A setting		

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

		10	Burn-out current sources enabled, 0.2- μ A setting		
		11	Burn-out current sources enabled, 1- μ A setting		

Filter Configuration 0 (0x24)

The filter configuration registers are 16-bit registers that configure the ADC data rate and filter options. Writing to any of these registers resets any active ADC conversion and restarts converting at the first channel in the sequence.

Bits	Bit Name	Settings	Description	Reset	Access
[15]	G_CHOP0		Global chop enable	0x0	RW
			Enables the global chop function. When enabled, the device automatically swaps the inputs and takes the average of two consecutive readings to cancel the offset voltage.		
		0	Disabled (default)		
		1	Enabled		
[14]	FILTER0		Configures the ADC to use either the sinc5 or the low-latency filter.	0x1	RW
		0	Sinc5 filter		
		1	Low-latency filter (default)		
[13:10]	DR0[3:0]		Configures the output data rate(1).	0x0100	RW
		0000	2.5 SPS		
		0001	5 SPS		
		0010	10 SPS		
		0011	16.6 SPS		
		0100	20 SPS (default)		
		0101	50 SPS		
		0110	60 SPS		
		0111	100 SPS		
		1000	200 SPS		
		1001	400 SPS		
		1010	800 SPS		
		1011	1000 SPS		
		1100	2000 SPS		
		1101	4000 SPS		
		1110	8000 SPS		
		1111	8000 SPS		
[9]	ENNOTCH0		Notch filter Enable for channel 0.	0x0	RW
[8:0]	RESERVED			0x0	RW

Filter Configuration N (0x25~27)

The filter configuration registers are 16-bit registers that configure the ADC data rate and filter options. Writing to any of these registers resets any active ADC conversion and restarts converting at the first channel in the sequence.

Bits	Bit Name	Settings	Description	Reset	Access

STATUS2 Register (0x32)					
Bits	Bit Name	Settings	Description	Reset	Access
[15:12]	RESERVED		RESERVED		
[11]	ADC_DET_OVRN G4		INT4 over-range flag: when 1 indicates over-range occurs	0	

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

[10]	ADC_DET_OVRN G3		INT3 over-range flag: when 1 indicates over-range occurs	0	
[9]	ADC_DET_OVRN G2		INT2 over-range flag: when 1 indicates over-range occurs	0	
[8]	ADC_DET_OVRN G1		INT1 over-range flag: when 1 indicates over-range occurs	0	
[7]	FL_POR		POR flag Indicates a power-on reset (POR) event has occurred.	1	RW
		0	Register has been cleared and no POR event has occurred.		
		1	POR event occurred and has not been cleared. Flag must be cleared by user register write (default).		
[6]	FL_UVLO		UVLO flag Indicates a UVLO event has occurred.	1	R
		0	Indicate UVLO is released.		
		1	Indicate UVLO has occurred.		
[5]	FL_P_RAILP		Positive PGA output at positive rail flag(1) Indicates the positive PGA output is within 150 mV of AVDD.	0	
		0	No error (default)		
		1	PGA positive output within 150 mV of AVDD		
[4]	FL_P_RAILN		Positive PGA output at negative rail flag(1) Indicates the positive PGA output is within 150 mV of AVSS.	0	
		0	No error (default)		
		1	PGA positive output within 150 mV of AVSS		
[3]	FL_N_RAILP		Negative PGA output at positive rail flag(1) Indicates the negative PGA output is within 150 mV of AVDD.	0	
		0	No error (default)		
		1	PGA negative output within 150 mV of AVDD		
[2]	FL_N_RAILN		Negative PGA output at negative rail flag(1) Indicates the negative PGA output is within 150 mV of AVSS.	0	
		0	No error (default)		
		1	PGA negative output within 150 mV of AVSS		
[1]	FL_REF_L1		Reference voltage monitor flag, level 1(2) Indicates the external reference voltage is lower than 1/3 of the analog supply voltage. Can be used to detect an open-excitation lead in a 3-wire RTD application.	0	
		0	Differential reference voltage $\geq 1/3 \cdot (AVDD - AVSS)$ (default)		
		1	Differential reference voltage $< 1/3 \cdot (AVDD - AVSS)$		
[0]	FL_REF_L0		Reference voltage monitor flag, level 0(2) Indicates the external reference voltage is lower than 0.3 V. Can be used to indicate a missing or floating external reference voltage.	0	

4-/8-Channel, 8-kSPS, 24-Bit, Highly Integrated Sigma-Delta ADC

	0	Differential reference voltage ≥ 0.3 V (default)	
	1	Differential reference voltage < 0.3 V	

Application and Implementation

Note

Information in the following application sections is not part of the 3PEAK's component specification and 3PEAK does not warrant its accuracy or completeness. 3PEAK's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

Application Information

The TPC62408 is supplied by several voltages.

Typical Configuration flow

The suggested flow to change the ADC configuration is as follows:

- Channel Configuration
- Setup Configuration
- ADC Mode and Interface Mode Configuration

Layout

Layout Guideline

- Both input capacitors and output capacitors must be placed to the device pins as close as possible.
- It is recommended to bypass the input pin to ground with a 0.1- μ F bypass capacitor.
- It is recommended to use wide and thick copper to minimize $I \times R$ drop and heat dissipation.
- Exposed pad must be connected to the PCB ground plane directly, the copper area must be as large as possible.
