產品規格說明書

The L78XX series of three-terminal positive regulators is available in TO-220, TO-220F, TO-252 and TO-252F packages and several fixed output voltages, making it useful in a wide range of applications.

TO-220

TO-220F

TO-252

TO-252F

- Output current up to 1.5 A
- Output voltages of 5; 6; 8; 8.5; 9; 12; 15; 18; 24 V
- Thermal overload protection
- Short circuit protection
- Output transition SOA protection
- 2 % output voltage tolerance (A version)
- Guaranteed in extended temperature range (A version)

The diagram illustrates the internal control loop of a buck converter. The input voltage V_I is connected to the top rail. The output voltage V_O is taken across the load inductor and capacitor. The control loop includes a **STARTING CIRCUIT** connected to the input and ground. A **REFERENCE VOLTAGE** block provides a reference to the **ERROR AMPLIFIER**. The **ERROR AMPLIFIER** also receives feedback from the output voltage divider (represented by two resistors) and drives the **SERIES PASS ELEMENT**. The **SERIES PASS ELEMENT** is connected to the input and the output. The **SOA PROTECTION** block monitors the input voltage and the output current (via a sense resistor) to prevent the power MOSFET from entering the safe operating area (SOA) limit. The **THERMAL PROTECTION** block monitors the junction temperature of the power MOSFET and provides feedback to the **ERROR AMPLIFIER** to reduce the duty cycle if the temperature exceeds a safe limit. The **CURRENT GENERATOR** block provides a current to the **REFERENCE VOLTAGE** block.

Application information

Design consideration

The L78XX Series of fixed voltage regulators are designed with thermal overload protection that shuts down the circuit when subjected to an excessive power overload condition, internal short-circuit protection that limits the maximum current the circuit will pass, and output transistor safe-area compensation that reduces the output shortcircuit current as the voltage across the pass transistor is increased. In many low current applications, compensation capacitors are not required. However, it is recommended that the regulator input be bypassed with capacitor if the regulator is connected to the power supply filter with long lengths, or if the output load capacitance is large. An input bypass capacitor should be selected to provide good high frequency characteristics to insure stable operation under all load conditions. A $0.33 \mu F$ or larger tantalum, mylar or other capacitor having low internal impedance at high frequencies should be chosen. The bypass capacitor should be mounted with the shortest possible leads directly across the regulators input

terminals. Normally good construction techniques should be used to minimize ground loops and lead resistance drops since the regulator has no external sense lead.

The addition of an operational amplifier allows adjustment to higher or intermediate values while retaining regulation characteristics. The minimum voltage obtained with the arrangement is 2 V greater than the regulator voltage.

The circuit of Figure 14. High current voltage regulator can be modified to provide supply protection against short circuit by adding a short circuit sense resistor, RSC, and an additional PNP transistor. The current sensing PNP must be able to handle the short circuit current of the three terminal regulator. Therefore a four ampere plastic power transistor is specified.

1. Although no output capacitor is need for stability, it does improve transient response.

Figure 28. Protection against input short-circuit with high capacitance loads

Note: Application with high capacitance loads and an output voltage greater than 6 volts need an external diode (see Figure 23. Reducing power dissipation with dropping resistor) to protect the device against input short circuit. In this case the input voltage falls rapidly while the output voltage decrease slowly. The capacitance discharges by means of the base-emitter junction of the series pass transistor in the regulator. If the energy is sufficiently high, the transistor may be destroyed. The external diode by-passes the current from the IC to ground.
